| singleton   | Whether the mount is a single backend store on the system                                                    |
| principal   | Agent (principal) invoking the current operation                                                             |
| owner       | Owner for new elements created (implicitly or explicitly) by the current operation                           |
| acl         | ACL for all new elements created (implicitly or explicitly) by the current operation                         |
| asof        | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes |
| read_only   | Whether the mount is read-only                                                                               |

### Usage Notes

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for information on mounting a registered store

## 53.7.39 NORMALIZEPATH Functions

This function converts a store-specific or full-absolute path name into normalized form.

It does the following:

- verifies that the path name is absolute, and so starts with "/"
- collapses multiple consecutive "/" into a single "/"
- strips trailing "/"
- breaks up a store-specific normalized path name into 2 components - parent pathname, trailing component name

- breaks up a full-absolute normalized path name into 3 components - store name, parent pathname, trailing component name

Syntax

```
DBMS_DBFS_CONTENT.NORMALIZEPATH (  
    path          IN          VARCHAR2,  
    parent        OUT NOCOPY   VARCHAR2,  
    tpath         OUT NOCOPY   VARCHAR2)  
RETURN VARCHAR2;  
  
DBMS_DBFS_CONTENT.NORMALIZEPATH (  
    path          IN          VARCHAR2,  
    store_name    OUT NOCOPY   VARCHAR2,  
    parent        OUT NOCOPY   VARCHAR2,  
    tpath         OUT NOCOPY   VARCHAR2)  
RETURN VARCHAR2;
```

Parameters

Table 53-51 NORMALIZEPATH Function Parameters

| Parameter  | Description                |
|------------|----------------------------|
| path       | Name of path to file items |
| store_name | Name of store              |
| parent     | Parent path name           |
| tpath      | Name of trailing path item |

Return Values

The completely normalized store-specific or full-absolute path name

53.7.40 PROPANY Functions

This function provides constructors that take one of a variety of types and return a PROPERTY\_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPANY (  
    val          IN          NUMBER)  
RETURN PROPERTY_T;  
  
DBMS_DBFS_CONTENT.PROPANY (  
    val          IN          VARCHAR2)  
RETURN PROPERTY_T;  
  
DBMS_DBFS_CONTENT.PROPANY (  
    val          IN          TIMESTAMP)  
RETURN PROPERTY_T;  
  
DBMS_DBFS_CONTENT.PROPANY (  
    val          IN          RAW)  
RETURN PROPERTY_T;
```

## Parameters

**Table 53-52 PROPANY Function Parameters**

| Parameter | Description |
|-----------|-------------|
| val       | Value       |

## Return Values

[PROPERTY\\_T Record Type](#)

## 53.7.41 PROPERTIESH2T Function

This function converts a `PROPERTY_T` hash to a `DBMS_DBFS_CONTENT_PROPERTIES_T` table.

### Syntax

```
DBMS_DBFS_CONTENT.PROPERTIESH2T (
    pprops      IN      PROPERTIES_T)
RETURN DBMS_DBFS_CONTENT_PROPERTIES_T;
```

## Parameters

**Table 53-53 PROPERTIESH2T Function Parameters**

| Parameter | Description                      |
|-----------|----------------------------------|
| sprops    | A <code>PROPERTIES_T</code> hash |

## Return Values

[DBMS\\_DBFS\\_CONTENT\\_PROPERTIES\\_T Table Type](#)

## 53.7.42 PROPERTIES2H Function

This function converts a `DBMS_DBFS_CONTENT_PROPERTIES_T` table to a `PROPERTY_T` hash.

### Syntax

```
DBMS_DBFS_CONTENT.PROPERTIES2H (
    sprops      IN      DBMS_DBFS_CONTENT_PROPERTIES_T)
RETURN properties_t;
```

## Parameters

**Table 53-54 PROPERTIES2H Function Parameters**

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| sprops    | A <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> table |

## Return Values

[PROPERTIES\\_T Table Type](#)

## 53.7.43 PROPNUMBER Function

This function is a constructor that takes a number and returns a `PROPERTY_T`.

### Syntax

```
DBMS_DBFS_CONTENT.PROPNUMBER (
    val      IN      NUMBER)
RETURN PROPERTY_T;
```

### Parameters

**Table 53-55** PROPNUMBER Function Parameters

| Parameter | Description |
|-----------|-------------|
| val       | Value       |

### Return Values

[PROPERTY\\_T Record Type](#)

## 53.7.44 PROPRAW Function

This function is a constructor that takes a `RAW` and returns a `PROPERTY_T`.

### Syntax

```
DBMS_DBFS_CONTENT.PROPRAW (
    val      IN      RAW)
RETURN PROPERTY_T;
```

### Parameters

**Table 53-56** PROPRAW Function Parameters

| Parameter | Description |
|-----------|-------------|
| val       | Value       |

### Return Values

[PROPERTY\\_T Record Type](#)

## 53.7.45 PROPTIMESTAMP Function

This function is a constructor that takes a `TIMESTAMP` and returns a `PROPERTY_T`.

### Syntax

```
DBMS_DBFS_CONTENT.PROPTIMESTAMP (
    val      IN      TIMESTAMP)
RETURN PROPERTY_T;
```

## Parameters

**Table 53-57 PROPTIMESTAMP Function Parameters**

| Parameter | Description |
|-----------|-------------|
| val       | Value       |

## Return Values

[PROPERTY\\_T Record Type](#)

## 53.7.46 PROPVARCHAR2 Function

This function is a constructor that takes a VARCHAR2 and returns a `PROPERTY_T`.

### Syntax

```
DBMS_DBFS_CONTENT.PROPVARCHAR2 (  
    val      IN      VARCHAR2)  
RETURN PROPERTY_T;
```

## Parameters

**Table 53-58 PROPNUMBER Function Parameters**

| Parameter | Description |
|-----------|-------------|
| val       | Value       |

## Return Values

[PROPERTY\\_T Record Type](#)

## 53.7.47 PURGEALL Procedure

This procedure purges all soft-deleted entries matching the path and optional filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT.PURGEALL (  
    path      IN      VARCHAR2,  
    filter     IN      VARCHAR2    DEFAULT NULL,  
    store_name IN      VARCHAR2    DEFAULT NULL,  
    principal  IN      VARCHAR2    DEFAULT NULL);
```

## Parameters

**Table 53-59 PURGEALL Procedure Parameters**

| Parameter  | Description                                                 |
|------------|-------------------------------------------------------------|
| path       | Name of path to file items                                  |
| filter     | A filter, if any, to be applied based on specified criteria |
| store_name | Name of store                                               |

**Table 53-59 (Cont.) PURGEALL Procedure Parameters**

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| principal | Agent (principal) invoking the current operation |

## 53.7.48 PURGEPATH Procedure

This procedure purges any soft-deleted versions of the given path item.

### Syntax

```
DBMS_DBFS_CONTENT.PURGEPATH (
    path          IN          VARCHAR2,
    filter         IN          VARCHAR2    DEFAULT NULL,
    store_name     IN          VARCHAR2    DEFAULT NULL,
    principal      IN          VARCHAR2    DEFAULT NULL);
```

### Parameters

**Table 53-60 PURGEPATH Procedure Parameters**

| Parameter  | Description                                      |
|------------|--------------------------------------------------|
| path       | Name of path to file items                       |
| filter     | A filter, if any, to be applied                  |
| store_name | Name of store                                    |
| principal  | Agent (principal) invoking the current operation |

## 53.7.49 PUTPATH Procedures

This procedure creates a new path item.

### Syntax

```
DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties     IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content        IN OUT NOCOPY BLOB,
    item_type      OUT          INTEGER,
    prop_flags     IN          INTEGER    DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    store_name     IN          VARCHAR2    DEFAULT NULL,
    principal      IN          VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties     IN OUT NOCOPY PROPERTIES_T,
    content        IN OUT NOCOPY BLOB,
    item_type      OUT          INTEGER,
    prop_flags     IN          INTEGER    DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    store_name     IN          VARCHAR2    DEFAULT NULL,
    principal      IN          VARCHAR2    DEFAULT NULL);
```

```

DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount        IN          NUMBER,
    offset        IN          NUMBER,
    buffer        IN          RAW,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT),

    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    amount        IN          NUMBER,
    offset        IN          NUMBER,
    buffer        IN          RAW,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT),

    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    written       OUT
    offset        IN          NUMBER,
    buffers       IN          DBMS_DBFS_CONTENT_RAW_T,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT),

    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    written       OUT
    offset        IN          NUMBER,
    buffers       IN          DBMS_DBFS_CONTENT_RAW_T,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT),

    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);

```

## Parameters

**Table 53-61 PUTPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to file items                                                                                                                 |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| content    | BLOB holding data which populates the file (optional)                                                                                      |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                          |
| amount     | Number of bytes to be read                                                                                                                 |

**Table 53-61 (Cont.) PUTPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| offset     | Byte offset from which to begin reading                                                                                                                                                                                                                    |
| buffer     | Buffer to which to write                                                                                                                                                                                                                                   |
| buffers    | Buffers to which to write                                                                                                                                                                                                                                  |
| prop_flags | Determines which properties are set. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| store_name | Name of store                                                                                                                                                                                                                                              |
| principal  | Agent (principal) invoking the current operation                                                                                                                                                                                                           |

## 53.7.50 REGISTERSTORE Procedure

This procedure registers a new store backed by a provider that uses a store provider (conforming to the DBMS\_DBFS\_CONTENT\_SPI package signature).

This method is to be used primarily by store providers after they have created a new store.

### Syntax

```
DBMS_DBFS_CONTENT.REGISTERSTORE (  
    store_name          IN      VARCHAR2,  
    provider_name       IN      VARCHAR2,  
    provider_package    IN      VARCHAR2);
```

### Parameters

**Table 53-62 REGISTERSTORE Procedure Parameters**

| Parameter        | Description                   |
|------------------|-------------------------------|
| store_name       | Name of store, must be unique |
| provider_name    | Name of provider              |
| provider_package | Store provider                |

## 53.7.51 RENAMEPATH Procedures

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

### Note:

See *Oracle Database SecureFiles and Large Objects Developer's Guide* for Rename and Move operations

## Syntax

```
DBMS_DBFS_CONTENT.RENAMEPATH (
    oldPath      IN          VARCHAR2,
    newPath      IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.RENAMEPATH (
    oldPath      IN          VARCHAR2,
    newPath      IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    store_name    IN          VARCHAR2    DEFAULT NULL,
    principal     IN          VARCHAR2    DEFAULT NULL);
```

## Parameters

**Table 53-63 RENAMEPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| oldPath    | Name of path prior to renaming                                                                                                             |
| newPath    | Name of path after renaming                                                                                                                |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| store_name | Name of store, must be unique                                                                                                              |
| principal  | Agent (principal) invoking the current operation                                                                                           |

## 53.7.52 RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

## Syntax

```
DBMS_DBFS_CONTENT.RESTOREALL (
    path          IN          VARCHAR2,
    filter         IN          VARCHAR2    DEFAULT NULL,
    store_name     IN          VARCHAR2    DEFAULT NULL,
    principal      IN          VARCHAR2    DEFAULT NULL);
```

## Parameters

**Table 53-64 RESTOREALL Procedure Parameters**

| Parameter  | Description                                      |
|------------|--------------------------------------------------|
| path       | Name of path to file items                       |
| filter     | A filter, if any, to be applied                  |
| store_name | Name of store                                    |
| principal  | Agent (principal) invoking the current operation |

## 53.7.53 RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT.RESTOREPATH (  
    path          IN          VARCHAR2,  
    filter        IN          VARCHAR2    DEFAULT NULL,  
    store_name    IN          VARCHAR2    DEFAULT NULL,  
    principal     IN          VARCHAR2    DEFAULT NULL);
```

### Parameters

**Table 53-65 RESTOREPATH Procedure Parameters**

| Parameter  | Description                                      |
|------------|--------------------------------------------------|
| path       | Name of path to file items                       |
| filter     | A filter, if any, to be applied                  |
| store_name | Name of store                                    |
| principal  | Agent (principal) invoking the current operation |

## 53.7.54 SETDEFAULTACL Procedure

This procedure sets the ACL parameter of the default context.

This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTACL (  
    acl          IN          VARCHAR2);
```

### Parameters

**Table 53-66 SETDEFAULTACL Procedure Parameters**

| Parameter | Description                                                                          |
|-----------|--------------------------------------------------------------------------------------|
| acl       | ACL for all new elements created (implicitly or explicitly) by the current operation |

### Usage Notes

- NULL by default, this parameter can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

## 53.7.55 SETDEFAULTASOF Procedure

This procedure sets the "as of" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTASOF (  
    asof      IN      TIMESTAMP);
```

### Parameters

**Table 53-67 SETDEFAULTASOF Procedure Parameters**

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| asof      | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes |

### Usage Notes

- NULL by default, this parameter be can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

## 53.7.56 SETDEFAULTCONTEXT Procedure

This procedure sets the default context. The information contained in the context can be inserted explicitly by way of arguments to the various method calls, allowing for fine-grained control over individual operations.

### Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTCONTEXT (  
    principal  IN      VARCHAR2,  
    owner      IN      VARCHAR2,  
    acl        IN      VARCHAR2,  
    asof       IN      TIMESTAMP);
```

### Parameters

**Table 53-68 SETDEFAULTCONTEXT Procedure Parameters**

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| principal | Agent (principal) invoking the current operation                                                             |
| owner     | Owner for new elements created (implicitly or explicitly) by the current operation                           |
| acl       | ACL for all new elements created (implicitly or explicitly) by the current operation                         |
| asof      | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes |

**Usage Notes**

- All of the context parameters are `NULL` by default, and be can be cleared by setting them to `NULL`.
- The context parameters, once set, remain as defaults for the duration of the session, and are inherited by all operations for which the defaults are not explicitly overridden.

## 53.7.57 SETDEFAULTOWNER Procedure

This procedure sets the "owner" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

**Syntax**

```
DBMS_DBFS_CONTENT.SETDEFAULTOWNER (  
    principal    IN    VARCHAR2);
```

**Parameters****Table 53-69 SETDEFAULTOWNER Procedure Parameters**

| Parameter | Description                                                                        |
|-----------|------------------------------------------------------------------------------------|
| owner     | Owner for new elements created (implicitly or explicitly) by the current operation |

**Usage Notes**

- `NULL` by default, this parameter be can be cleared by setting it to `NULL`.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

## 53.7.58 SETDEFAULTPRINCIPAL Procedure

This procedure sets the "principal" parameter of the default context. This information contained can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

**Syntax**

```
DBMS_DBFS_CONTENT.SETDEFAULTPRINCIPAL (  
    principal    IN    VARCHAR2);
```

**Parameters****Table 53-70 SETDEFAULTPRINCIPAL Procedure Parameters**

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| principal | Agent (principal) invoking the current operation |

**Usage Notes**

- `NULL` by default, this parameter be can be cleared by setting it to `NULL`.

- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

## 53.7.59 SETPATH Procedures

This procedure assigns a path name to a path item represented by contentID.

Stores and their providers that support contentID-based access and lazy path name binding also support the SETPATH Procedure that associates an existing contentID with a new path.

### Note:

See *Oracle Database SecureFiles and Large Objects Developer's Guide* for Rename and Move operations

### Syntax

```
DBMS_DBFS_CONTENT.SETPATH (
    store_name IN          VARCHAR2,
    contentID  IN          RAW,
    path       IN          VARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    principal  IN          VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.SETPATH (
    store_name IN          VARCHAR2,
    contentID  IN          RAW,
    path       IN          VARCHAR2,
    properties IN OUT NOCOPY PROPERTIES_T,
    principal  IN          VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 53-71 SETPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of the store                                                                                                                          |
| contentID  | Unique identifier for the item to be associated                                                                                            |
| path       | Name of path to path item                                                                                                                  |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| principal  | Agent (principal) invoking the current operation                                                                                           |

## 53.7.60 SETSTATS Procedure

This procedure enables and disables statistics collection.

The client can optionally control the flush settings by specifying non-NULL values for the time, count or both parameters.

## Syntax

```
DBMS_DBFS_CONTENT.SETSTATS (
    enable           IN    BOOLEAN,
    flush_time       IN    INTEGER,
    flush_count      IN    INTEGER);
```

## Parameters

**Table 53-72 SETSTATS Procedure Parameters**

| Parameter   | Description                                                                     |
|-------------|---------------------------------------------------------------------------------|
| enable      | If TRUE, enable statistics collection. If FALSE, disable statistics collection. |
| flush_time  | How often to flush the statistics to disk in centiseconds                       |
| flush_count | Number of operations to allow between statistics flushes                        |

## Usage Notes

The SETSTATS Procedure buffers statistics in-memory for a maximum of `flush_time` centiseconds or a maximum of `flush_count` operations (whichever limit is reached first), or both, at which time the buffers are implicitly flushed to disk.

## 53.7.61 SETTRACE Procedure

This procedure sets the DBMS\_DBFS\_CONTENT tracing severity to the given level, 0 being "off".

## Syntax

```
DBMS_DBFS_CONTENT.SETTRACE
    trclvl          IN    INTEGER);
```

## Parameters

**Table 53-73 SETTRACE Procedure Parameters**

| Parameter | Description                                               |
|-----------|-----------------------------------------------------------|
| trclvl    | Level of the tracing, higher values implying more tracing |

## 53.7.62 SPACEUSAGE Procedure

This procedure queries file system space usage statistics.

Providers are expected to support this subprogram for their stores (and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on).

## Syntax

```
DBMS_DBFS_CONTENT.SPACEUSAGE (
    path            IN    VARCHAR2,
    blksize         OUT   INTEGER,
    tbytes          OUT   INTEGER,
```

```
fbytes      OUT      INTEGER,
nfile       OUT      INTEGER,
ndir        OUT      INTEGER,
nlink       OUT      INTEGER,
nref        OUT      INTEGER,
store_name  IN        VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 53-74 SPACEUSAGE Procedure Parameters**

| Parameter  | Description                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to file items                                                                                                                        |
| blksize    | Natural tablespace blocksize that holds the store. If multiple tablespaces with different blocksizes are used, any valid blocksize is acceptable. |
| tbytes     | Total size of the store in bytes computed over all segments that comprise the store                                                               |
| fbytes     | Free or unused size of the store in bytes computed over all segments that comprise the store                                                      |
| nfile      | Number of currently available files in the store                                                                                                  |
| ndir       | Number of currently available directories in the store                                                                                            |
| nlink      | Number of currently available links in the store                                                                                                  |
| nref       | Number of currently available references in the store                                                                                             |
| store_name | Name of store                                                                                                                                     |

## Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.

## 53.7.63 TRACE Procedure

This procedure outputs tracing to the current foreground trace file.

### Syntax

```
DBMS_DBFS_CONTENT.TRACE
sev          IN          INTEGER,
msg0         IN          VARCHAR2,
msg1         IN          VARCHAR  DEFAULT '',
msg2         IN          VARCHAR  DEFAULT '',
msg3         IN          VARCHAR  DEFAULT '',
msg4         IN          VARCHAR  DEFAULT '',
msg5         IN          VARCHAR  DEFAULT '',
msg6         IN          VARCHAR  DEFAULT '',
msg7         IN          VARCHAR  DEFAULT '',
msg8         IN          VARCHAR  DEFAULT '',
msg9         IN          VARCHAR  DEFAULT '',
msg10        IN          VARCHAR  DEFAULT '' );
```

## Parameters

**Table 53-75 TRACE Procedure Parameters**

| Parameter | Description                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------|
| sev       | Severity at which trace message is output                                                        |
| msg*      | One or more message strings to be output. If more than one message is specified, all are output. |

## Usage Notes

- Trace information is written to the foreground trace file, with varying levels of detail as specified by the trace level arguments.
- The global trace level consists of 2 components: "severity" and "detail". These can be thought of as additive bitmasks.

The "severity" allows the separation of top level as compared to low-level tracing of different components, and allows the amount of tracing to be increased as needed. There are no semantics associated with different levels, and users are free to set trace at any severity they choose, although a good rule of thumb would use severity "1" for top level API entry and exit traces, "2" for internal operations, and "3" or greater for very low-level traces.

The "detail" controls how much additional information: timestamps, short-stack, etc. is dumped along with each trace record.

## 53.7.64 TRACEENABLED Function

This function determines if the current trace "severity" set by the SETTRACE Procedure is at least as high as the given trace level.

### Syntax

```
DBMS_DBFS_CONTENT.TRACEENABLED(  
    sev          IN          INTEGER)  
RETURN INTEGER;
```

## Parameters

**Table 53-76 TRACEENABLED Procedure Parameters**

| Parameter | Description                               |
|-----------|-------------------------------------------|
| sev       | Severity at which trace message is output |

## Return Values

Returns 0 if the requested severity level is lower than the currently set trace severity level; 1 otherwise.

## Related Topics

- [SETTRACE Procedure](#)  
This procedure sets the DBMS\_DBFS\_CONTENT tracing severity to the given level, 0 being "off".

## 53.7.65 UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

### Syntax

```
DBMS_DBFS_CONTENT.UNLOCKPATH (  
    path            IN      VARCHAR2,  
    who             IN      VARCHAR2,  
    waitForRowLock  IN      INTEGER    DEFAULT 1,  
    store_name      IN      VARCHAR2   DEFAULT NULL,  
    principal       IN      VARCHAR2   DEFAULT NULL);
```

### Parameters

**Table 53-77 UNLOCKPATH Procedure Parameters**

| Parameter      | Description                                           |
|----------------|-------------------------------------------------------|
| path           | Name of path to file items                            |
| who            | Transaction identifier that has locked the path       |
| waitForRowLock | Determines if a row is locked by a transaction or not |
| store_name     | Name of store                                         |
| principal      | Agent (principal) invoking the current operation      |

### Related Topics

- [LOCKPATH Procedure](#)  
This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

## 53.7.66 UNMOUNTSTORE Procedure

This procedure unmounts a registered store, either by name or by mount point.

### Syntax

```
DBMS_DBFS_CONTENT.UNMOUNTSTORE (  
    store_name      IN      VARCHAR2   DEFAULT NULL,  
    store_mount     IN      VARCHAR2   DEFAULT NULL,  
    ignore_unknown  IN      BOOLEAN    DEFAULT FALSE);
```

### Parameters

**Table 53-78 UNMOUNTSTORE Procedure Parameters**

| Parameter      | Description                                                                 |
|----------------|-----------------------------------------------------------------------------|
| store_name     | Name of store                                                               |
| store_mount    | Location at which the store instance is mounted                             |
| ignore_unknown | If TRUE, attempts to unregister unknown stores will not raise an exception. |

## Usage Notes

### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on unmounting a previously unmounted store

## 53.7.67 UNREGISTERSTORE Procedure

This procedure unregisters a previously registered store (invalidating all mount points associated with it).

### Syntax

```
DBMS_DBFS_CONTENT.UNREGISTERSTORE (  
    store_name          IN          VARCHAR2,  
    ignore_unknown      IN          BOOLEAN DEFAULT FALSE);
```

### Parameters

**Table 53-79 UNREGISTERSTORE Procedure Parameters**

| Parameter      | Description                                                                 |
|----------------|-----------------------------------------------------------------------------|
| store_name     | Name of store                                                               |
| ignore_unknown | If TRUE, attempts to unregister unknown stores will not raise an exception. |

### Usage Notes

- Once unregistered all access to the store (and its mount points) are not guaranteed to work
- If the `ignore_unknown` argument is TRUE, attempts to unregister unknown stores do not raise an exception.

# DBMS\_DBFS\_CONTENT\_SPI

The `DBMS_DBFS_CONTENT_SPI` package is a specification for `DBMS_DBFS_CONTENT` store providers, which must be implemented. Application designers can create PL/SQL packages conforming to this specification to extend `DBMS_DBFS_CONTENT` to use custom store providers.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Operational Notes](#)
- [Summary of DBMS\\_DBFS\\_CONTENT\\_SPI Subprograms](#)

## Related Topics

- [DBMS\\_DBFS\\_CONTENT](#)  
The `DBMS_DBFS_CONTENT` package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

## 54.1 ODBMS\_DBFS\_CONTENT\_SPI Overview

The `DBMS_DBFS_CONTENT_SPI` package describes an internal contract between the implementation of the `DBMS_DBFS_CONTENT` interface and individual store providers, and whichever package contains their code.

Since PL/SQL does not allow a compile-time, declarative type-conformation between package signatures, store providers should informally conform to the SPI, which is to say, they should implement the SPI by means of a package that contains all of the methods specified in package `DBMS_DBFS_CONTENT_SPI`, with the same method signatures and semantics.

Obviously, these provider packages can implement other methods and expose other interfaces, however, these interfaces are not to be used by the `DBMS_DBFS_CONTENT` interface itself.

Since the provider SPI is merely a contract specification, there is no package body for `DBMS_DBFS_CONTENT_SPI`, and it is not possible to actually invoke any methods using this package.

The SPI references various elements (constants, types, exceptions) defined by the `DBMS_DBFS_CONTENT` interface.

Additionally, there is an almost one-to-one correspondence between the client API exported by the `DBMS_DBFS_CONTENT` interface and the provider interface that the `DBMS_DBFS_CONTENT` interface itself expects to work against.

The main distinction in the method naming conventions is that all path name references are always store-qualified. That is, the notion of mount-points and full-absolute path names have been normalized and converted to store-qualified path names by the `DBMS_DBFS_CONTENT` interface before it invokes any of the provider SPI methods.

Since the interconnection of the `DBMS_DBFS_CONTENT` interface and the provider SPI is a 1-to-many pluggable architecture, and the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

#### Related Topics

- [DBMS\\_DBFS\\_CONTENT](#)  
The `DBMS_DBFS_CONTENT` package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

## 54.2 DBMS\_DBFS\_CONTENT\_SPI Security Model

Implementations of the `DBMS_DBFS_CONTENT_SPI` package should be created as `AUTHID CURRENT_USER`.

## 54.3 DBMS\_DBFS\_CONTENT\_SPI Operational Notes

This topic lists operational notes for `DBMS_DBFS_CONTENT_SPI` implementation, path names, and other operations.

- [Implementation](#)
- [Path Names](#)
- [Other DBMS\\_DBFS\\_CONTENT Operations](#)

#### Implementation

Since the interconnection of the `DBMS_DBFS_CONTENT` interface and the provider SPI is a 1-to-many pluggable architecture, the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

There are no explicit `INIT` or `FINI` methods to indicate when the `DBMS_DBFS_CONTENT` interface plugs or unplugs a particular provider SPI. Provider SPIs must be willing to auto-initialize themselves at any SPI entry-point.

All operations performed by a store provider are "stateless" in that they are complete operations unto themselves. If state is necessary to be maintained for some reason, then the state must be maintained in data structures such as auxiliary tables that can be queried as needed.

#### Path Names

All path names used in the provider SPI are store-qualified in pair form (`store_name, pathname`) where the path name is rooted within the store namespace.

Stores and their providers that support contentID-based access (see `FEATURE_CONTENT_ID` in [Table 53-5](#)) also support a form of addressing that is not based on path names. Content items

are identified by an explicit store name, a `NULL` path name, and possibly a contentID specified as a parameter or by way of the `OPT_CONTENT_ID` (see [Table 53-8](#)) property.

Not all operations are supported with contentID-based access, and applications should depend only on the simplest create or delete functionality being available.

### Other DBMS\_DBFS\_CONTENT Operations

This table lists other operations and provides links to related discussions.

**Table 54-1 Other DBMS\_DBFS\_CONTENT Operations**

| Other Operations                | See ...                                                                                                                            |

## 54.4 Summary of DBMS\_DBFS\_CONTENT\_SPI Subprograms

This table lists and describes the subprograms used in the `DBMS_DBFS_CONTENT_SPI` Package.

**Table 54-2 DBMS\_DBFS\_CONTENT\_SPI Package Subprograms**

| Subprogram                                | Description                                                                                    |
|-------------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">CHECKACCESS Function</a>      | Reports if the user (principal) can perform the specified operation on the given path          |
| <a href="#">CREATEDIRECTORY Procedure</a> | Creates a directory                                                                            |
| <a href="#">CREATEFILE Procedure</a>      | Creates a file                                                                                 |
| <a href="#">CREATELINK Procedure</a>      | Creates a physical link to an already existing file system element                             |
| <a href="#">CREATEREFERENCE Procedure</a> | Creates a new reference to the source file system element                                      |
| <a href="#">DELETECONTENT Procedure</a>   | Deletes the file specified by the given contentID                                              |
| <a href="#">DELETEDIRECTORY Procedure</a> | Deletes a directory                                                                            |
| <a href="#">DELETEFILE Procedure</a>      | Deletes a file                                                                                 |
| <a href="#">GETFEATURES Function</a>      | Returns the features of a store                                                                |
| <a href="#">GETPATH Procedures</a>        | Returns existing path items (such as files and directories)                                    |
| <a href="#">GETPATHBYSTOREID Function</a> | If the underlying GUID is found in the underlying store, returns the store-qualified path name |

**Table 54-2 (Cont.) DBMS\_DBFS\_CONTENT\_SPI Package Subprograms**

| Subprogram                              | Description                                                                                                                                           |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GETPATHNOWAIT Procedure</a> | Implies that the operation is for an update, and, if implemented, allows providers to return an exception (ORA-00054) rather than wait for row locks. |
| <a href="#">GETSTOREID Function</a>     | Returns the ID of a store                                                                                                                             |
| <a href="#">GETVERSION Function</a>     | Returns the version associated with a store                                                                                                           |
| <a href="#">LIST Function</a>           | Lists the contents of a directory path name                                                                                                           |
| <a href="#">LOCKPATH Procedure</a>      | Applies user-level locks to the given valid path name                                                                                                 |
| <a href="#">PURGEALL Procedure</a>      | Purges all soft-deleted entries matching the path and optional filter criteria                                                                        |
| <a href="#">PURGEPATH Procedure</a>     | Purges any soft-deleted versions of the given path item                                                                                               |
| <a href="#">PUTPATH Procedures</a>      | Creates a new path item                                                                                                                               |
| <a href="#">RENAMEPATH Procedure</a>    | Renames or moves a path                                                                                                                               |
| <a href="#">RESTOREALL Procedure</a>    | Restores all soft-deleted path items meeting the path and filter criteria                                                                             |
| <a href="#">RESTOREPATH Procedure</a>   | Restores all soft-deleted path items that match the given path and filter criteria                                                                    |
| <a href="#">SEARCH Function</a>         | Searches for path items matching the given path and filter criteria                                                                                   |
| <a href="#">SETPATH Procedure</a>       | Assigns a path name to a path item represented by contentID                                                                                           |
| <a href="#">SPACEUSAGE Procedure</a>    | Queries file system space usage statistics                                                                                                            |
| <a href="#">UNLOCKPATH Procedure</a>    | Unlocks path items that were previously locked with the <a href="#">LOCKPATH Procedure</a>                                                            |

## 54.4.1 CHECKACCESS Function

This function reports if the user (*principal*) can perform the specified operation on the given path. This enables verifying the validity of an operation without attempting to perform the operation. If `CHECKACCESS` returns 0, then the subprogram invoked to implement that operation should fail with an error.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.CHECKACCESS (
    store_name    IN    VARCHAR2  DEFAULT NULL,
    path          IN    VARCHAR2,
    pathtype      IN    INTEGER,
    operation     IN    VARCHAR2,
    principal     IN    VARCHAR2)
RETURN INTEGER;
```

### Parameters

**Table 54-3 CHECKACCESS Procedure Parameters**

| Parameter               | Description                      |
|-------------------------|----------------------------------|
| <code>store_name</code> | Name of store                    |
| <code>path</code>       | Name of path to check for access |

**Table 54-3 (Cont.) CHECKACCESS Procedure Parameters**

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| pathtype  | Type of object path represents (see <a href="#">Table 53-4</a> ) |
| operation | Operation to be checked (see <a href="#">Table 53-8</a> )        |
| principal | File system user for whom the access check is made               |

**Usage Notes**

Whether or not the user invokes this function, a store that supports access control internally performs these checks to guarantee security.

## 54.4.2 CREATEDIRECTORY Procedure

This procedure creates a directory.

**Syntax**

```
DBMS_DBFS_CONTENT_SPI.CREATEDIRECTORY (  
    store_name  IN          VARCHAR2,  
    path        IN          VARCHAR2,  
    properties  IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,  
    prop_flags  IN          INTEGER,  
    recurse     IN          INTEGER,  
    ctx         IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

**Parameters****Table 54-4 CREATEDIRECTORY Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                                                                             |
| path       | Name of path to the directory                                                                                                                                                                                                                                                                                                             |
| properties | One or more properties and their values to be set, returned, or both, depending on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                                                               |
| prop_flags | Determines which properties are set, returned, or both. Default is <code>PROP_STD</code> . Specify properties to be returned by setting <code>PROP_SPC</code> (see <a href="#">Table 53-9</a> ), and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| recurse    | If 0, do not execute recursively; otherwise, recursively create the directories above the given directory                                                                                                                                                                                                                                 |
| ctx        | Context with which to create the directory (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                                                                                                                                                                 |

## 54.4.3 CREATEFILE Procedure

This procedure creates a file.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATEFILE (
  store_name    IN          VARCHAR2,
  path          IN          VARCHAR2,
  properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
  content       IN OUT NOCOPY BLOB,
  prop_flags    IN          INTEGER,
  ctx           IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-5 CREATEFILE Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                                             |
| path       | Name of path to the file                                                                                                                                                                                                                                                                                  |
| properties | One or more properties and their values to be set, returned or both depending, or both on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                        |
| content    | BLOB holding data with which to populate the file (optional)                                                                                                                                                                                                                                              |
| prop_flags | Determines which properties are set, returned, or both. Default is <code>PROP_STD</code> . Specify properties to be returned by setting <code>prop_spec</code> , and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| ctx        | Context with which to create the file (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                                                                                                                                      |

## 54.4.4 CREATELINK Procedure

This procedure creates a physical link to an already existing file system element (such as file or directory). The resulting entry shares the same metadata structures as the value of the `srcPath` parameter, and so is similar to incrementing a reference count on the file system element. This is analogous to a UNIX file system hard link.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATELINK (
  store_name    IN          VARCHAR2,
  srcPath       IN          VARCHAR2,
  dstPath       IN          VARCHAR2,
  properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
  prop_flags    IN          INTEGER,
  ctx           IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-6 CREATELINK Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                 |
| srcPath    | File system entry with which to link                                                                                                                                                                                                                                          |
| dstPath    | Path of the new link element to be created                                                                                                                                                                                                                                    |
| properties | One or more properties and their values to be set, returned, or both, depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                |
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| ctx        | Context with which to create the link (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                                                                                                          |

## 54.4.5 CREATEREERENCE Procedure

This procedure creates a new reference to the source file system element (such as a file, or directory). The resulting reference points to the source element but does not directly share metadata with the source element. This is analogous to a UNIX file system symbolic link.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATEREERENCE (
  srcPath      IN          VARCHAR2,
  dstPath      IN          VARCHAR2,
  properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
  prop_flags    IN          INTEGER,
  store_name    IN          VARCHAR2,
  ctx          IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-7 CREATEREERENCE Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                 |
| srcPath    | File system entry with which to link                                                                                                                                                                                                                                          |
| dstPath    | Path of the new link element to be created                                                                                                                                                                                                                                    |
| properties | One or more properties and their values to be set, returned, or both, depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                |
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |

**Table 54-7 (Cont.) CREATEREERENCE Procedure Parameters**

| Parameter | Description                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------|
| ctx       | Context with which to create the reference (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.6 DELETECONTENT Procedure

This procedure deletes the file specified by the given contentID.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETECONTENT (
    store_name      IN      VARCHAR2,
    contentID       IN      RAW,
    filter          IN      VARCHAR2,
    soft_delete     IN      INTEGER,
    ctx             IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-8 DELETECONTENT Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name  | Name of store                                                                                                                                                                                 |
| contentID   | Unique identifier for the file to be deleted                                                                                                                                                  |
| filter      | A filter, if any, to be applied                                                                                                                                                               |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations). |
| ctx         | Context with which to delete the file (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                          |

## 54.4.7 DELETEDIRECTORY Procedure

This procedure deletes a directory.

If `recurse` is nonzero, it recursively deletes all elements of the directory. A filter, if supplied, determines which elements of the directory are deleted.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETEDIRECTORY (
    store_name      IN      VARCHAR2,
    path           IN      VARCHAR2,
    filter          IN      VARCHAR2,
    soft_delete     IN      INTEGER,
    recurse        IN      INTEGER,
    ctx            IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-9 DELETEDIRECTORY Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name  | Name of store                                                                                                                                                                                 |
| path        | Name of path to the directory                                                                                                                                                                 |
| filter      | A filter, if any, to be applied                                                                                                                                                               |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations). |
| recurse     | If 0, do not execute recursively. Otherwise, recursively delete the directories and files below the given directory.                                                                          |
| ctx         | Context with which to delete the directory (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                     |

## 54.4.8 DELETEFILE Procedure

This procedure deletes the specified file.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETEFILE (
    store_name    IN    VARCHAR2,
    path          IN    VARCHAR2,
    filter        IN    VARCHAR2,
    soft_delete   IN    BOOLEAN,
    ctx           IN    DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-10 DELETEFILE Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name  | Name of store                                                                                                                                                                                 |
| path        | Name of path to the file                                                                                                                                                                      |
| filter      | A filter, if any, to be applied                                                                                                                                                               |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations). |
| ctx         | Context with which to delete the file (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                          |

## 54.4.9 GETFEATURES Function

This function returns the features of a store.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.GETFEATURES (
    store_name      IN      VARCHAR2)
RETURN  INTEGER;
```

### Parameters

**Table 54-11 GETFEATURES Function Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

### Return Values

DBMS\_DBFS\_CONTENT.FEATURE\_\* features supported by the Store Provider

## 54.4.10 GETPATH Procedures

This procedure returns existing path items (such as files and directories). This includes both data and metadata (properties).

The client can request (using `prop_flags`) that specific properties be returned. File path names can be read either by specifying a BLOB locator using the `prop_data` bitmask in `prop_flags` (see [Table 53-9](#)) or by passing one or more RAW buffers.

When `forUpdate` is 0, this procedure also accepts a valid "as of" timestamp parameter as part of `ctx` that can be used by stores to implement "as of" style flashback queries. Mutating versions of the GETPATH Procedures do not support these modes of operation.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name  IN      VARCHAR2,
    path        IN      VARCHAR2,
    properties  IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content     OUT      NOCOPY BLOB,
    item_type   OUT      INTEGER,
    prop_flags  IN      INTEGER,
    forUpdate   IN      INTEGER,
    deref       IN      INTEGER,
    ctx         IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name  IN      VARCHAR2,
    path        IN      VARCHAR2,
    properties  IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount     IN OUT      NUMBER,
    offset      IN      NUMBER,
    buffer      OUT      NOCOPY RAW,
    prop_flags  IN      INTEGER,
    ctx         IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

```

DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name IN          VARCHAR2,
    path       IN          VARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount     IN OUT      NUMBER,
    offset     IN          NUMBER,
    buffers    OUT         NOCOPY DBMS_DBFS_CONTENT_RAW_T,
    prop_flags IN          INTEGER,
    ctx        IN          DBMS_DBFS_CONTENT_CONTEXT_T);

```

## Parameters

**Table 54-12 GETPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                 |
| path       | Name of path to path items                                                                                                                                                                                                                                                    |
| properties | One or more properties and their values to be returned depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                               |
| content    | BLOB holding data which populates the file (optional)                                                                                                                                                                                                                         |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                                                                                                                                                             |
| amount     | On input, number of bytes to be read. On output, number of bytes read                                                                                                                                                                                                         |
| offset     | Byte offset from which to begin reading                                                                                                                                                                                                                                       |
| buffer     | Buffer to which to write                                                                                                                                                                                                                                                      |
| buffers    | Buffers to which to write                                                                                                                                                                                                                                                     |
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| forUpdate  | Specifies that a lock should be taken to signify exclusive write access to the path item                                                                                                                                                                                      |
| deref      | If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link)                                                                                                                                                                 |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                                                                                                    |

## 54.4.11 GETPATHBYSTOREID Function

If the underlying GUID is found in the underlying store, this function returns the store-qualified path name.

### Syntax

```

DBMS_DBFS_CONTENT_SPI.GETPATHBYSTOREID (
    store_name IN          VARCHAR2,
    guid       IN          INTEGER)
RETURN VARCHAR2;

```

## Parameters

**Table 54-13 GETPATHBYSTOREID Function Parameters**

| Parameter  | Description                                  |
|------------|----------------------------------------------|
| store_name | Name of store                                |
| guid       | Unique ID representing the desired path item |

## Return Values

Store-qualified path name represented by the GUID

## Usage Notes

If the `STD_GUID` is unknown, a `NULL` value is returned. Clients are expected to handle this as appropriate.

## 54.4.12 GETPATHNOWAIT Procedure

This procedure implies that the operation is for an update, and, if implemented, allows providers to return an exception (ORA-00054) rather than wait for row locks.

See `FEATURE_NOWAIT` in [Table 53-5](#) for more information.

## Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATHNOWAIT (
    store_name IN          VARCHAR2,
    path       IN          VARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content    OUT NOCOPY  BLOB,
    item_type  OUT          INTEGER,
    prop_flags IN          INTEGER,
    deref      IN          INTEGER,
    ctx        IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-14 GETPATHNOWAIT Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                                                                                                                                                               |
| path       | Name of path to path items                                                                                                                                                                                                                                                                  |
| properties | One or more properties and their values to be returned depending on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                                |
| content    | BLOB holding data which populates the file (optional)                                                                                                                                                                                                                                       |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                                                                                                                                                                           |
| prop_flags | Determines which properties are returned. Default is <code>PROP_STD</code> . Specify properties to be returned by setting <code>prop_spec</code> , and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |

**Table 54-14 (Cont.) GETPATHNOWAIT Procedure Parameters**

| Parameter | Description                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------|
| deref     | If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link) |
| ctx       | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )    |

## 54.4.13 GETSTOREID Function

This function returns the ID of a store.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.GETSTOREID (  
    store_name      IN      VARCHAR2)  
RETURN NUMBER;
```

### Parameters

**Table 54-15 GETSTOREID Function Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

### Return Values

ID of the Store

### Usage Notes

A store ID identifies a provider-specific store, across registrations and mounts, but independent of changes to the store contents. For this reason, changes to the store table or tables should be reflected in the store ID, but re-initialization of the same store table or tables should preserve the store ID.

## 54.4.14 GETVERSION Function

This function returns the version associated with a store.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.GETVERSION (  
    store_name      IN      VARCHAR2)  
RETURN VARCHAR2;
```

### Parameters

**Table 54-16 GETVERSION Function Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

## Return Values

A "version" (either specific to a provider package, or to an individual store) based on a standard *a.b.c* naming convention (for *major*, *minor*, and *patch* components)

## 54.4.15 ISPATHLOCKED Procedure

This procedure checks if any user-level locks are applied on a given path.

### Syntax

```
DBMS_DBFS_CONTENT.ISPATHLOCKED (
    store_name    IN    VARCHAR2,
    path          IN    VARCHAR2,
    who           IN    VARCHAR2,
    lock_type     IN OUT INTEGER,
    ctx           IN    DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-17** ISPATHLOCKED Procedure Parameters

| Parameter  | Description                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                              |
| path       | Path name of items to be locked                                                                            |
| who        | Transaction identifier that has locked the path                                                            |
| lock_type  | One of the available lock types (see <a href="#">Table 53-6</a> )                                          |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.16 LIST Function

This function lists the contents of a directory path name.

The invoker of the subprogram has the option to investigate recursively into sub-directories, to make soft-deleted items visible, to use a flashback "as of" a specified timestamp, and to filter items within the store based on list predicates.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.LIST (
    store_name    IN    VARCHAR2,
    path          IN    VARCHAR2,
    filter        IN    VARCHAR2,
    recurse       IN    INTEGER,
    ctx           IN    DBMS_DBFS_CONTENT_CONTEXT_T)
RETURN DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

## Parameters

**Table 54-18 LIST Function Parameters**

| Parameter  | Description                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of repository                                                                                                             |
| path       | Name of path to directories                                                                                                    |
| filter     | A filter, if any, to be applied                                                                                                |
| recurse    | If 0, do not execute recursively. Otherwise, recursively list the contents of directories and files below the given directory. |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                     |

## Return Values

Path items found that match the path, filter and criteria for executing recursively (see [DBMS\\_DBFS\\_CONTENT\\_LIST\\_ITEMS\\_T Table Type](#))

## Usage Notes

This function returns only list items; the client is expected to explicitly use one of the [GETPATH Procedures](#) to access the properties or content associated with an item.

## 54.4.17 LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

## Syntax

```
DBMS_DBFS_CONTENT_SPI.LOCKPATH (
    store_name    IN    VARCHAR2,
    path          IN    VARCHAR2,
    who           IN    VARCHAR2,
    lock_type     IN    INTEGER,
    waitForRowLock IN    INTEGER,
    ctx           IN    DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-19 LOCKPATH Procedure Parameters**

| Parameter      | Description                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------|
| store_name     | Name of store                                                                                              |
| path           | Path name of items to be locked                                                                            |
| who            | Transaction identifier that has locked the path                                                            |
| lock_type      | One of the available lock types (see <a href="#">Table 53-6</a> )                                          |
| waitForRowLock | Determines if a row is locked by a transaction or not                                                      |
| ctx            | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

### Usage Notes

- It is the responsibility of the store and its providers (assuming it supports user-defined lock checking) to ensure that lock and unlock operations are performed in a consistent manner.
- The status of locked items is available by means of various optional properties (see `OPT_LOCK*` in [Table 53-8](#)).

## 54.4.18 PURGEALL Procedure

This procedure purges all soft-deleted entries matching the path and optional filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.PURGEALL (
    store_name    IN      VARCHAR2,
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2,
    ctx           IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-20 PURGEALL Procedure Parameters**

| Parameter  | Description                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                              |
| path       | Name of path to file items                                                                                 |
| filter     | A filter, if any, to be applied based on specified criteria                                                |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.19 PURGEPATH Procedure

This procedure purges any soft-deleted versions of the given path item.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.PURGEPATH (
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2,
    store_name    IN      VARCHAR2,
    ctx           IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-21 PURGEPATH Procedure Parameters**

| Parameter  | Description                     |
|------------|---------------------------------|
| store_name | Name of store                   |
| path       | Name of path to file items      |
| filter     | A filter, if any, to be applied |

**Table 54-21 (Cont.) PURGEPATH Procedure Parameters**

| Parameter | Description                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------|
| ctx       | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.20 PUTPATH Procedures

This procedure creates a new path item.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name    IN          VARCHAR2,
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content       IN OUT NOCOPY BLOB,
    item_type     OUT          INTEGER,
    prop_flags    IN          INTEGER,
    ctx           IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

```
DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name    IN          VARCHAR2,
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount       IN          NUMBER,
    offset        IN          NUMBER,
    buffer        IN          RAW,
    prop_flags    IN          INTEGER,
    ctx           IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

```
DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name    IN          VARCHAR2,
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    written       OUT          NUMBER,
    offset        IN          NUMBER,
    buffers       IN          DBMS_DBFS_CONTENT_RAW_T,
    prop_flags    IN          INTEGER,
    ctx           IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-22 PUTPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                              |
| path       | Path name of item to be put                                                                                                                |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| content    | BLOB holding data which populates the file (optional)                                                                                      |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                          |
| amount     | Number of bytes to be read                                                                                                                 |

**Table 54-22 (Cont.) PUTPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| written    | Number of bytes written                                                                                                                                                                                                                                    |
| offset     | Byte offset from which to begin reading                                                                                                                                                                                                                    |
| buffer     | Buffer to which to write                                                                                                                                                                                                                                   |
| buffers    | Buffers to which to write                                                                                                                                                                                                                                  |
| prop_flags | Determines which properties are set. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                                                                                                                                 |

**Usage Notes**

- All path names allow their metadata (properties) to be read and modified. On completion of the call, the client can access specific properties using prop\_flags (see [Table 53-9](#)).
- On completion of the call, the client can request a new BLOB locator that can be used to continue data access using the prop\_data bitmask in prop\_flags (see [Table 53-9](#)).
- Files can also be written without using BLOB locators, by explicitly specifying logical offsets or buffer-amounts, and a suitably sized buffer.

## 54.4.21 RENAMEPATH Procedure

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

**Note:**

See *Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations

**Syntax**

```
DBMS_DBFS_CONTENT_SPI.RENAMEPATH (
  store_name      IN          VARCHAR2,
  oldPath         IN          VARCHAR2,
  newPath         IN          VARCHAR2,
  properties      IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
  ctx             IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

**Parameters****Table 54-23 RENAMEPATH Procedure Parameters**

| Parameter  | Description                   |
|------------|-------------------------------|
| store_name | Name of store, must be unique |

**Table 54-23 (Cont.) RENAMEPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| oldPath    | Name of path prior to renaming                                                                                                             |
| newPath    | Name of path after renaming                                                                                                                |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                 |

## 54.4.22 RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.RESTOREALL (
    store_name    IN      VARCHAR2,
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2,
    ctx           IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-24 RESTOREALL Procedure Parameters**

| Parameter  | Description                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                              |
| path       | Name of path to path items                                                                                 |
| filter     | A filter, if any, to be applied                                                                            |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.23 RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.RESTOREPATH (
    store_name    IN      VARCHAR2,
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2,
    ctx           IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-25** RESTOREPATH Procedure Parameters

| Parameter  | Description                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                              |
| path       | Name of path to path items                                                                                 |
| filter     | A filter, if any, to be applied                                                                            |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

## 54.4.24 SEARCH Function

This function searches for path items matching the given path and filter criteria.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.SEARCH (
    store_name    IN      VARCHAR2,
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2,
    recurse       IN      INTEGER,
    ctx           IN      DBMS_DBFS_CONTENT_CONTEXT_T)
RETURN DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

## Parameters

**Table 54-26** LIST Function Parameters

| Parameter  | Description                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                    |
| path       | Name of path to the path items                                                                                                   |
| filter     | A filter, if any, to be applied                                                                                                  |
| recurse    | If 0, do not execute recursively. Otherwise, recursively search the contents of directories and files below the given directory. |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                       |

### Return Values

Path items matching the given path and filter criteria (see [DBMS\\_DBFS\\_CONTENT\\_LIST\\_ITEMS\\_T Table Type](#))

## 54.4.25 SETPATH Procedure

This procedure assigns a path name to a path item represented by contentID.

Stores and their providers that support contentID-based access and lazy path name binding also support the SETPATH Procedure that associates an existing contentID with a new path.

#### Note:

See *Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations

### Syntax

```
DBMS_DBFS_CONTENT_SPI.SETPATH (
    store_name    IN          VARCHAR2,
    contentID     IN          RAW,
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    ctx          IN          DBMS_DBFS_CONTENT_CONTEXT_T);
```

### Parameters

**Table 54-27 SETPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of the store                                                                                                                          |
| contentID  | Unique identifier for the item to be associated                                                                                            |
| path       | Name of path to path item                                                                                                                  |
| properties | One or more properties and their values to be set depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| ctx        | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> )                                 |

## 54.4.26 SPACEUSAGE Procedure

This procedure queries file system space usage statistics.

Providers are expected to support this subprogram for their stores and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.SPACEUSAGE (
    store_name    IN          VARCHAR2,
    blksize      OUT         INTEGER,
    tbytes       OUT         INTEGER,
    fbytes       OUT         INTEGER,
    nfile        OUT         INTEGER,
    ndir         OUT         INTEGER,
    nlink        OUT         INTEGER,
    nref         OUT         INTEGER);
```

## Parameters

**Table 54-28 SPACEUSAGE Procedure Parameters**

| Parameter  | Description                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                                     |
| blksize    | Natural tablespace blocksize that holds the store. If multiple tablespaces with different blocksizes are used, any valid blocksize is acceptable. |
| tbytes     | Total size of the store in bytes computed over all segments that comprise the store                                                               |
| fbytes     | Free or unused size of the store in bytes computed over all segments that comprise the store                                                      |
| nfile      | Number of currently available files in the store                                                                                                  |
| ndir       | Number of currently available directories in the store                                                                                            |
| nlink      | Number of currently available links in the store                                                                                                  |
| nref       | Number of currently available references in the store                                                                                             |

## Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, it is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.

## 54.4.27 UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

### Syntax

```
DBMS_DBFS_CONTENT_SPI.UNLOCKPATH (
    store_name    IN    VARCHAR2,
    path          IN    VARCHAR2,
    who           IN    VARCHAR2,
    waitForRowLock IN    INTEGER,
    ctx           IN    DBMS_DBFS_CONTENT_CONTEXT_T);
```

## Parameters

**Table 54-29 UNLOCKPATH Procedure Parameters**

| Parameter      | Description                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------|
| store_name     | Name of store                                                                                              |
| path           | Name of path to the path items                                                                             |
| who            | Transaction identifier that has locked the path                                                            |
| waitForRowLock | Determines if a row is locked by a transaction or not                                                      |
| ctx            | Context with which to access the path items (see <a href="#">DBMS_DBFS_CONTENT_CONTEXT_T Object Type</a> ) |

### Related Topics

- [LOCKPATH Procedure](#)  
This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

# DBMS\_DBFS\_HS

The Oracle Database File System Hierarchical Store is implemented in the `DBMS_DBFS_HS` package. This package provides users the ability to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management for their database tables.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Operational Notes](#)
- [Summary of DBMS\\_DBFS\\_HS Subprograms](#)

## See Also:

- *Oracle Database SecureFiles and Large Objects Developer's Guide*

## 55.1 DBMS\_DBFS\_HS Overview

The `DBMS_DBFS_HS` package is a service provider underneath the `DBMS_DBFS_CONTENT` package that enables use of tape or Amazon S3 Web service as storage for data.

The data on tape or Amazon S3 Web service is part of the Oracle Database and can be accessed through all standard interfaces, but only through the database. The package allows users to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management of their content.

The package initially stores all content files in level-1 cache. As the level-1 cache fills up, content files are moved to level-2 cache and then to an external storage device using bulk writes.

## 55.2 DBMS\_DBFS\_HS Security Model

The `DBMS_DBFS_HS` package runs with invoker's rights.

## 55.3 DBMS\_DBFS\_HS Constants

The `DBMS_DBFS_HS` package uses the constants shown in the tables in this topic.

**Table 55-1 DBMS\_DBFS\_HS Constants - Used by the CREATESTORE Procedure**

| Constant               | Type          | Value     | Description                                 |
|------------------------|---------------|-----------|---------------------------------------------|
| STORETYPE_TAPE         | VARCHAR2 (50) | 'HS_TAPE' | Use tape as a storage tier                  |
| STORETYPE_AMAZON<br>S3 | VARCHAR2 (50) | 'HS_S3'   | Use Amazon S3 Web service as a storage tier |

**Table 55-2 DBMS\_DBFS\_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function**

| Constant                  | Type          | Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|---------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROPNAME_BUCKET           | VARCHAR2 (50) | 'BUCKET'            | Specifies the AWS bucket to be used as a storage tier by the Hierarchical Store.<br>Restrictions on bucket name are:<br>1) Bucket names can only contain lowercase letters, numbers, periods (.) and dashes(-). Note that underscores (_) are invalid.<br>2) Bucket names must start with a number or letter.<br>3) Bucket names cannot be in an IP address style (192.168.5.4).<br>4) Bucket names must be between 3 and 63 characters long.<br>5) Bucket names should not end with a dash.<br>6) Dashes cannot appear next to periods. For example, my-.bucket.com is invalid. |
| PROPNAME_CACHESIZE        | VARCHAR2 (50) | 'CACHE_SIZE'        | Specifies the cumulative cache size used for the Hierarchical Store. This property is set by the <a href="#">CREATESTORE Procedure</a> and can be modified by the <a href="#">RECONFIGCACHE Procedure</a> . It cannot be modified by the <a href="#">SETSTOREPROPERTY Procedure</a> , though its value can be queried by the <a href="#">GETSTOREPROPERTY Function</a> .                                                                                                                                                                                                         |
| PROPNAME_COMPRESSIONLEVEL | VARCHAR2 (50) | 'COMPRESSION_LEVEL' | Use to enable compression of files stored in the DBFS hierarchical store. It specifies the compression level to be used for compressing the files                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 55-2 (Cont.) DBMS\_DBFS\_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function**

| Constant                       | Type          | Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|---------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROPNAME_ENABLECLEANUPONDELETE | VARCHAR2 (50) | 'ENABLE_CLEANUP_ON_DELETE' | If this property is set to 'TRUE', whenever the user invokes the <a href="#">DELETEFILE Procedure</a> in the <a href="#">DBMS_DBFS_CONTENT</a> interface on a file residing in the DBMS_DBFS_HS store, the DBMS_DBFS_HS removes the file on the external storage that contains this user file, provided that the file has no other useful data. By default, the property is set to 'TRUE' for <a href="#">STORETYPE_AMAZONS3</a> and 'FALSE' for <a href="#">STORETYPE_TAPE</a> .                                                            |
| PROPNAME_HTTPPROXY             | VARCHAR2 (50) | 'HTTP_PROXY'               | Specifies the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PROPNAME_LICENSEID             | VARCHAR2 (50) | 'LICENSE_ID'               | Specifies the license ID associated with the library <code>libosbws11.so</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PROPNAME_LOBCACHE_QUOTA        | VARCHAR2 (50) | 'LOBCACHE_QUOTA'           | Specifies fraction of the <code>cache_size</code> which is allocated for level 1 cache. The default value of this parameter is <code>NULL</code> which means that 0.8 (= 80%) of the <code>cache_size</code> is used for level 1 cache. This property cannot be modified by the <a href="#">SETSTOREPROPERTY Procedure</a> though its value can be queried by the <a href="#">GETSTOREPROPERTY Function</a> . Its value is set by <a href="#">CREATESTORE Procedure</a> and can be modified by the <a href="#">RECONFIGCACHE Procedure</a> . |
| PROPNAME_MEDIAPOOL             | VARCHAR2 (50) | 'MEDIA_POOL'               | Specifies the media pool number to use for storing the content                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PROPVAL_COMPLVL_NONE           | VARCHAR2 (50) | 'NONE'                     | Indicates no compression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PROPVAL_COMPLVL_LOW            | VARCHAR2 (50) | 'LOW'                      | Use to set the compression level to <code>LOW</code> . This is expected to have the best performance while still providing a good compression ratio.                                                                                                                                                                                                                                                                                                                                                                                         |
| PROPVAL_COMPLVL_MEDIUM         | VARCHAR2 (50) | 'MEDIUM'                   | Use to set the compression level to <code>MEDIUM</code> . This compression level is expected to provide better compression ratio than <code>LOW</code> but the time required for compression will be higher than compression level <code>LOW</code> .                                                                                                                                                                                                                                                                                        |
| PROPVAL_COMPLVL_HIGH           | VARCHAR2 (50) | 'HIGH'                     | Use to set the compression level to <code>HIGH</code> . This compression level is expected to provide the best compression ratio but compression time will in general be highest among the 3 compression levels.                                                                                                                                                                                                                                                                                                                             |

**Table 55-2 (Cont.) DBMS\_DBFS\_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function**

| Constant                    | Type         | Value                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|--------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROPNAME_OPTTARB<br>ALLSIZE | VARCHAR2(50) | 'OPTIMAL_TARBALL_SIZE' | <p>Specifies <code>optimal_tarball_size</code> as the maximum possible size of an archive file.</p> <p>Multiple content files are bundled together into one archive file and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation.</p> <p>This property cannot be modified by the <a href="#">SETSTOREPROPERTY Procedure</a> though its value can be queried by the <a href="#">GETSTOREPROPERTY Function</a>. Its value is set by <a href="#">CREATESTORE Procedure</a> and can be modified by the <a href="#">RECONFIGCACHE Procedure</a>.</p> |
| PROPNAME_READCHUNK<br>SIZE  | VARCHAR2(50) | 'READ_CHUNK_SIZE'      | <p>Specifies the size used by the SBT protocol to transfer data from tape or S3. This chunk is allocated in memory per transaction for retrieval of content files from an archive store, so the value of this property should be conservative. The default size of 1MB is typically good for most users.</p>                                                                                                                                                                                                                                                                                                                                                                             |
| PROPNAME_S3HOST             | VARCHAR2(50) | 'S3_HOST'              | <p>Specifies the <code>HOST</code> name of the Amazon S3 storage service. It must be <code>s3.amazonaws.com</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PROPNAME_SBT_LIBRARY        | VARCHAR2(50) | 'SBT_LIBRARY'          | <p>Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named <code>libosbws11.so</code> and is available in <code>rdbms/lib</code> directory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PROPNAME_STREAMABLE         | VARCHAR2(50) | 'STREAMABLE'           | <p>Indicates whether buffer-based <code>PUT</code> or <code>GET</code> should be done on this store. Valid values for are <code>TRUE</code> and <code>FALSE</code>. The default value of this property is <code>TRUE</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 55-2 (Cont.) DBMS\_DBFS\_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function**

| Constant                | Type         | Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROPNAME_WALLET         | VARCHAR2(50) | 'WALLET'           | <p>The value of this property should be of the form:</p> <pre>LOCATION=file:filename CREDENTIAL_ALIAS=access/secret_alias PROXY_AUTH_ALIAS=proxyusername/password alias</pre> <p>Defines the Oracle Wallet which contains the credentials of the Amazon S3 account associated with the store under consideration.</p> <p>LOCATION: The directory path that contains the Oracle wallet. The format is <code>file:directory-path</code></p> <p>The format of <code>wallet_path</code> in Windows is, for example:</p> <pre>file:c:\WINNT\Profiles\username\WALLETS</pre> <p>In UNIX or Linux it is, for example:</p> <pre>file:/home/username/wallets</pre> <p>When the package is executed in the Oracle database server, the wallet is accessed from the database server.</p> <p>PASSWORD: Defines the wallet password. If auto-login is enabled in wallet (this can be changed using the OWM utility), this parameter does not have to be specified. By default, the <code>mkstore</code> utility enables auto-login.</p> <p>CREDENTIAL_ALIAS: Defines the credential alias for ACCESS_KEY and SECRET_KEY</p> |
| PROPNAME_WRITECHUNKSIZE | VARCHAR2(50) | 'WRITE_CHUNK_SIZE' | <p>Specifies the size used by the SBT protocol to transfer data to tape or S3.</p> <p>This chunk is allocated in memory per transaction for PUT of Content Files to an archive store so the value should be conservative.</p> <p>The default size of 1MB is typically good for most users.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 55-3 DBMS\_DBFS\_HS Constants - Used by the REGISTERSTORECOMMAND Function**

| Constant   | Type   | Value | Description                                                                                                            |
|------------|--------|-------|------------------------------------------------------------------------------------------------------------------------|
| BEFORE_PUT | NUMBER | '1'   | Specified operation must be performed before writing a SECUREFILE to the remote store                                  |
| BEFORE_GET | NUMBER | '2'   | Specified operation must be performed before a retrieval operation such as reading a SECUREFILE from the remote device |

**Table 55-4 DBMS\_DBFS\_HS Constants - Failure/Success/Error**

| Constant | Type   | Value | Description                                        |
|----------|--------|-------|----------------------------------------------------|
| FAIL     | NUMBER | '0'   | Procedure or function did not execute successfully |
| SUCCESS  | NUMBER | '1'   | Procedure or function completed successfully       |
| ERROR    | NUMBER | '2'   | Procedure or function returned an error            |

## 55.4 DBMS\_DBFS\_HS Operational Notes

When the DBMS\_DBFS\_HS package is executed in the Oracle database server, the wallet is accessed from the database server.

## 55.5 Summary of DBMS\_DBFS\_HS Subprograms

This table lists and describes the subprograms in the DBMS\_DBFS\_HS package.

**Table 55-5 DBMS\_DBFS\_HS Package Subprograms**

| Subprogram                                         | Description                                                                                                                                 |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CLEANUPUNUSEDBACKUPFILES Procedure</a> | Removes files created on the external storage device that hold no currently used data                                                       |
| <a href="#">CREATEBUCKET Procedure</a>             | Creates an AWS bucket, associated with a store of type <code>STORETYPE_AMAZONS3</code> into which the Hierarchical Store can then move data |
| <a href="#">CREATESTORE Procedure</a>              | Creates a new hierarchical store                                                                                                            |
| <a href="#">DEREGSTORECOMMAND Function</a>         | Removes a command that had been previously associated with a store through the <a href="#">RECONFIGCACHE Procedure</a>                      |
| <a href="#">DROPSTORE Procedure</a>                | Deletes a previously created hierarchical store                                                                                             |
| <a href="#">FLUSHCACHE Procedure</a>               | Flushes (writes out) dirty contents from the level-1 cache.                                                                                 |
| <a href="#">GETSTOREPROPERTY Function</a>          | Retrieves the values of a property of a store                                                                                               |
| <a href="#">RECONFIGCACHE Procedure</a>            | Reconfigures the parameters of the database cache used by the store                                                                         |

**Table 55-5 (Cont.) DBMS\_DBFS\_HS Package Subprograms**

| Subprogram                                     | Description                                                                                                                                          |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">REGISTERSTORECOMMAND Procedure</a> | Registers commands for a store with the Hierarchical Store to be sent to the Media Manager for the external storage device associated with the store |
| <a href="#">SENDCOMMAND Procedures</a>         | Sends a command to be executed on the external storage device's Media Manager                                                                        |
| <a href="#">SETSTOREPROPERTY Procedure</a>     | Stores properties of a store in the database                                                                                                         |
| <a href="#">STOREPUSH Procedure</a>            | Pushes locally staged data to the remote storage                                                                                                     |

## 55.5.1 CLEANUPUNUSEDBACKUPFILES Procedure

This procedure removes files created on the external storage device that hold no currently used data in them.

### Syntax

```
DBMS_DBFS_HS.CLEANUPUNUSEDBACKUPFILES (  
    store_name      IN      VARCHAR2);
```

### Parameters

**Table 55-6 CLEANUPUNUSEDBACKUPFILES Procedure Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

### Usage Notes

- The action of removing files from external storage device can not be rolled back.
- This method can be executed periodically to clear space on the external storage device. Asynchronously deleting content from the external storage device is useful because it has minimal impact on the OLTP performance. The periodic scheduling can be accomplished using the DBMS\_SCHEDULER package.

## 55.5.2 CREATEBUCKET Procedure

This procedure creates an AWS bucket, associated with a store of type `STORETYPE_AMAZONS3` into which the Hierarchical Store can then move data.

### Syntax

```
DBMS_DBFS_HS.CREATEBUCKET (  
    store_name      IN      VARCHAR2);
```

## Parameters

**Table 55-7 CREATEBUCKET Procedure Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

## Usage Notes

- The `PROPNAME_BUCKET` property of the store should be set before this subprogram is called.
- Once this procedure has successfully created a bucket in Amazon S3, the bucket can only be deleted using out-of-band methods, such as logging-in to S3 and deleting data (directories, files, and other items) for the bucket.

## 55.5.3 CREATESTORE Procedure

This procedure creates a new hierarchical store `store_name` of type `STORE_TYPE` (`STORETYPE_TAPE` or `STORETYPE_AMAZONS3`) in schema `schema_name` (defaulting to the current schema) under the ownership of the invoking session user.

## Syntax

```
DBMS_DBFS_HS.CREATESTORE (
    store_name      IN      VARCHAR2,
    store_type      IN      VARCHAR2,
    tbl_name        IN      VARCHAR2,
    tbs_name        IN      VARCHAR2,
    cache_size      IN      NUMBER,
    lob_cache_quota IN      NUMBER DEFAULT NULL,
    optimal_tarball_size IN    NUMBER DEFAULT NULL,
    schema_name     IN      VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 55-8 CREATESTORE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name      | Name of store                                                                                                                                                                                                                 |
| store_type      | <code>STORETYPE_TAPE</code> or <code>STORETYPE_AMAZONS3</code>                                                                                                                                                                |
| tbl_name        | Table for store entries                                                                                                                                                                                                       |
| tbs_name        | Tablespace for the store                                                                                                                                                                                                      |
| cache_size      | Amount of space used by the store to cache content in given tablespace                                                                                                                                                        |
| lob_cache_quota | Fraction of the <code>cache_size</code> which is allocated for level 1 cache. The default value of this parameter is <code>NULL</code> which means that 0.8 (= 80%) of the <code>cache_size</code> is used for level 1 cache. |

**Table 55-8 (Cont.) CREATESTORE Procedure Parameters**

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>optimal_tarball_size</code> | Maximum possible size of the archive file.<br>Multiple content files are bundled together into one archive file, and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation.<br>The value of is set by default to 10GB for tape and to 100MB for Amazon S3. |
| <code>schema_name</code>          | Schema for the store                                                                                                                                                                                                                                                                                                                                                                              |

### Usage Notes

`CREATESTORE()` sets certain properties of the store to default values. The user can use the methods `SETSTOREPROPERTY()` and `RECONFIGCACHE()` to appropriately change the property values and to set other properties of the store.

- Store names must be unique for an owner. The same store names can be used for different stores owned by different owners.
- Once a table space has been specified to store the store's content in a database, it cannot be changed later.
- This subprogram will execute like a DDL statement, performing an automatic `COMMIT` before and after execution.
- Stores using `DBMS_DBFS_HS` must not use singleton mount. This means that the singleton parameter should be `FALSE` and the `store_mount` parameter should have a non-NULL value in a call to the `DBMS_DBFS_CONTENT.MOUNTSTORE` procedure.

## 55.5.4 DEREGSTORECOMMAND Function

This procedure removes a command that had been previously associated with a store through the `REGISTERSTORECOMMAND` Procedure.

### Syntax

```
DBMS_DBFS_HS.DEREGSTORECOMMAND (  
    store_name      IN      VARCHAR2,  
    message         IN      VARCHAR2);
```

### Parameters

**Table 55-9 DEREGSTORECOMMAND Procedure Parameters**

| Parameter               | Description                |
|-------------------------|----------------------------|
| <code>store_name</code> | Name of store              |
| <code>message</code>    | Message to be deregistered |

### Usage Notes

If this subprogram successfully executes, its actions cannot be rolled back by the user. If the user wants to restore the previous state, the user must call the [REGISTERSTORECOMMAND Procedure](#).

### Related Topics

- [REGISTERSTORECOMMAND Procedure](#)  
This procedure registers commands for a store with the Hierarchical Store. These commands are sent to the Media Manager for the external storage device associated with the store.

## 55.5.5 DROPSTORE Procedure

This procedure deletes a previously created hierarchical store specified by name and owned by the invoking session user.

### Syntax

```
DBMS_DBFS_HS.DROPSTORE (
    store_name  IN      VARCHAR2,
    opt_flags   IN      INTEGER DEFAULT 0);
```

### Parameters

**Table 55-10 DROPSTORE Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store owned by the invoking session user                                                                                                                                                                                                                                                            |
| opt_flags  | User can specify optional flags. If <code>DISABLE_CLEANUPBACKUPFILES</code> is specified as one of the optional flags, the call to the <a href="#">CLEANUPUNUSEDBACKUPFILES Procedure</a> is not issued. By default, when this flag is not set, the procedure implicitly cleans-up all unused backup files. |

### Usage Notes

- The procedure executes like a DDL in that it auto-commits before and after its execution.
- If `CLEANUPBACKUPFILES` is disabled during the procedure, the user must resort to out-of-band techniques to cleanup unused backup files. No further invocations of `CLEANUPBACKFILES` for a dropped store are possible through hierarchical store.
- This subprogram will un-register the store from `DBMS_DBFS_CONTENT` package. All files in the given store are deleted from the store (Tape or Amazon S3 Web service). The database table holding the store's entries in the database, is also dropped by this subprogram.

## 55.5.6 FLUSHCACHE Procedure

This procedure flushes out dirty contents from level-1 cache, which can be locked, to level-2 cache, thereby freeing-up space in level 1 cache.

### Syntax

```
DBMS_DBFS_HS.FLUSHCACHE (
    store_name    IN    VARCHAR2);
```

### Parameters

**Table 55-11 FLUSHCACHE Procedure Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

## 55.5.7 GETSTOREPROPERTY Function

This function retrieves the values of a property.

### Syntax

```
DBMS_DBFS_HS.GETSTOREPROPERTY (
    store_name      IN    VARCHAR2,
    property_name    IN    VARCHAR2,
    noexcp          IN    BOOLEAN DEFAULT FALSE) RETURN VARCHAR2;
```

### Parameters

**Table 55-12 GETSTOREPROPERTY Function Parameters**

| Parameter     | Description                                                                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name    | Name of store                                                                                                                                                                                                     |
| property_name | Name of property                                                                                                                                                                                                  |
| noexcp        | If set to <code>FALSE</code> , raises an exception if the property does not exist in the database. If <code>noexcp</code> is set to <code>TRUE</code> , returns <code>NULL</code> if the property does not exist. |

### Return Values

The values of a property.

### Usage Notes

The specified store must already have been created.

## 55.5.8 RECONFIGCACHE Procedure

This procedure reconfigures the parameters of the database cache being used by the store.

### Syntax

```
DBMS_DBFS_HS.RECONFIGCACHE (
    store_name          IN    VARCHAR2,
    cache_size          IN    NUMBER DEFAULT NULL,
    lobcache_quota      IN    NUMBER DEFAULT NULL,
    optimal_tarball_size IN    NUMBER DEFAULT NULL);
```

### Parameters

**Table 55-13 RECONFIGCACHE Procedure Parameters**

| Parameter            | Description                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name           | Name of store                                                                                                                                                                                                                                      |
| cache_size           | Cumulative cache size used for the Hierarchical Store                                                                                                                                                                                              |
| lobcache_quota       | Fraction of the cache size that are assigned to level 1 cache                                                                                                                                                                                      |
| optimal_tarball_size | Maximum possible size of an archive file. Since creating one file for every content file in the store is a prohibitively expensive operation, multiple content files are bundled together into one archive file for transfer to tape or Amazon S3. |

### Usage Notes

- The specified store must already have been created before reconfiguration.
- The Hierarchical Store uses a level 1 cache and a level 2 cache. The level 1 cache subsumes most of the working set and the level 2 cache is used to perform bulk writes to the backend device.
- If any of the last 3 parameters is `NULL`, its value specified during store creation is used. If the parameter was `NULL` when the call to the [CREATESTORE Procedure](#) was issued, the `DBMS_DBFS_HS` package assigns a default value.

The `DBMS_DBFS_HS` package optimistically tries to allocate more than 1 tarball's worth of size for level 2 cache to facilitate concurrency, though a minimum of 1 tarball size is necessary for level 2 cache.

The values for cumulative cache size and LOB cache quota decide allocation of space for the two caches. If values are not provided, a user might see an `INSUFFICIENT_CACHE` exception. In that case, it is better to revise the cache parameters in order to have a working store.

- If this subprogram successfully executes, its actions cannot be rolled back by the user. In that case, the user should call `RECONFIGCACHE` again with new or modified parameters.

## 55.5.9 REGISTERSTORECOMMAND Procedure

This procedure registers commands for a store with the Hierarchical Store. These commands are sent to the Media Manager for the external storage device associated with the store.

### Syntax

```
DBMS_DBFS_HS.REGISTERSTORECOMMAND (  
    store_name      IN      VARCHAR2,  
    message         IN      VARCHAR2,  
    flags           IN      NUMBER);
```

### Parameters

**Table 55-14 REGISTERSTORECOMMAND Procedure Parameters**

| Parameter  | Description                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store                                                                                                                           |
| message    | Message to be sent to the Media Manager of the external store                                                                           |
| flags      | Valid values: <ul style="list-style-type: none"><li>BEFORE_PUT CONSTANT NUMBER := 1;</li><li>BEFORE_GET CONSTANT NUMBER := 2;</li></ul> |

### Usage Notes

- These commands are sent before the next read or write of content. When the Hierarchical Store wants to push (or get) data to (or from) the storage device, it begins a session (to communicate with the device). After beginning the session, it sends all registered commands for the to the relevant device before writing (or getting) any data.
- If this method successfully executes, its actions cannot be rolled back by the user. To restore the previous state the user must call the [DEREGSTORECOMMAND Function](#).

## 55.5.10 SENDCOMMAND Procedure

This procedure sends a command to be executed on the external storage device's Media Manager.

### Syntax

```
DBMS_DBFS_HS.SENDCOMMAND (  
    store_name      IN      VARCHAR2,  
    message         IN      VARCHAR2);
```

### Parameters

**Table 55-15 SENDCOMMAND Procedure Parameters**

| Parameter  | Description                   |
|------------|-------------------------------|
| store_name | Name of store                 |
| message    | Message string to be executed |

## 55.5.11 SETSTOREPROPERTY Procedure

This procedure stores properties of a store in the database as name-value pairs.

### Syntax

```
DBMS_DBFS_HS.SETSTOREPROPERTY (
    store_name      IN      VARCHAR2,
    property_name   IN      VARCHAR2,
    property_value  IN      VARCHAR2);
```

### Parameters

**Table 55-16 SETSTOREPROPERTY Procedure Parameters**

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name     | Name of store                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| property_name  | For a store using Tape device, there are three properties whose values must be set by the user, and four properties that have default values. Stores of type STORETYPE_AMAZONS3 have properties with default values. The various options for both types of stores are detailed under property_value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| property_value | <p><b>Stores using a Tape Device</b></p> <p>The values for the following properties must be set by the user:</p> <ul style="list-style-type: none"> <li>PROPNAME_SBTLIBRARY - This should point to the shared library used by RMAN to communicate with the external tape device. It is usually named libobk.so.</li> <li>PROPNAME_MEDIAPOL - Media pool number for storing content</li> <li>PROPNAME_CACHE_SIZE - Amount of space, in bytes, used for the cache of this store</li> </ul> <p>The following properties, which have default values assigned to them when a store is created, benefit from tuning:</p> <ul style="list-style-type: none"> <li>PROPNAME_READCHUNKSIZE and PROPNAME_WRITECHUNKSIZE - These are the sizes used by the SBT protocol to transfer data to and from the tapes. These chunks are allocated in memory per transaction, so the values should be conservative. The default size is 1MB.</li> <li>PROPNAME_STREAMABLE – Indicates whether DBFS_LINKS can perform read operations (for example SELECT or DBMS_LOB.READ) directly from the store, or if the data must be copied back into the database before it can be read</li> <li>PROPNAME_ENABLECLEANUPONDELETE - Indicates if DBMS_DBFS_HS should delete unused files on the external storage. Valid values for this property are 'FALSE' for STORETYPE_TAPE.</li> <li>PROPNAME_COMPRESSLEVEL - Describes how files written to Tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.</li> </ul> |

**Table 55-16 (Cont.) SETSTOREPROPERTY Procedure Parameters**

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (cont) property_value | <p><b>Stores of type STORETYPE_AMAZONS3</b></p> <p>It is mandatory that the following properties have assigned values, and default values are provided:</p> <ul style="list-style-type: none"> <li>• <b>PROPNAME_SBTLIBRARY</b> - Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named <code>libosbws11.so</code> and is available in <code>rdbms/lib</code> directory.</li> <li>• <b>PROPNAME_S3HOST</b> - Defines the HOST name of the Amazon S3 storage service. It must be <code>s3.amazonaws.com</code>.</li> <li>• <b>PROPNAME_BUCKET</b> - Defines the AWS bucket used as a storage tier by the Hierarchical Store. Restrictions on bucket names are: <ul style="list-style-type: none"> <li>-- Bucket names can only contain lowercase letters, numbers, periods (.) and dashes (-). Use of an underscore ( ) is invalid.</li> <li>-- Bucket names must start with a number or letter</li> <li>-- Bucket names cannot be in an IP address style ("192.168.5.4")</li> <li>-- Bucket names must be between 3 and 63 characters in length</li> <li>-- Bucket names should not end with a dash</li> <li>-- Dashes cannot appear next to periods. For example, "my-.bucket.com" is invalid.</li> </ul> </li> <li>• <b>PROPNAME_LICENSEID</b> - Specifies the license ID associated with the library <code>libosbws11.so</code>.</li> <li>• <b>PROPNAME_WALLET</b> - Has the form: 'LOCATION=file:&lt;filename&gt; CREDENTIAL_ALIAS=&lt;access/secret_alias&gt; PROXY_AUTH_ALIAS=&lt;proxyusername/password alias&gt;' <ul style="list-style-type: none"> <li>-- <b>LOCATION</b> - Directory path that contains the Oracle wallet. The format is <code>file:directory-path</code>. See <a href="#">Examples</a> for variations in format.</li> <li>-- <b>PASSWORD</b> - Defines the wallet password. If auto-login is enabled in the wallet (this can be changed using the user's own utility), and does not have to be specified. By default, the <code>mkstore</code> utility enables auto-login.</li> <li>-- <b>CREDENTIAL_ALIAS</b> - Defines the credential alias for <code>ACCESS_KEY</code> and <code>SECRET_KEY</code></li> <li>-- <b>PROXY_AUTH_ALIAS</b> - Defines authentication credentials for the proxy server, if applicable.</li> </ul> </li> </ul> |

**Table 55-16 (Cont.) SETSTOREPROPERTY Procedure Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (property_value (contd.)) | <p>The following properties are optional:</p> <ul style="list-style-type: none"> <li>PROPNAME_HTTPPROXY - Defines the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service.</li> <li>PROPNAME_STREAMABLE – Indicates whether buffer-based PUT or GET operation should be done on this store. Valid values for this property are TRUE (default) and FALSE.</li> <li>PROPNAME_ENABLECLEANUPONDELETE - Indicates if DBMS_DBFS_HS should delete unused files on the external storage device. Default values for this property are FALSE for STORETYPE_TAPE and TRUE for STORETYPE_AMAZONS3.</li> <li>PROPNAME_COMPRESSLEVEL - Describes how files written to tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.</li> </ul> |

#### Usage Notes

- The specified store must already have been created.
- If this subprogram successfully executes, its actions cannot be rolled back by the user.
- The same property can be set multiple times to the same or different values using this subprogram
- Regarding PROPNAME\_ENABLECLEANUPONDELETE behavior, a job is created for each store by the DBMS\_DBFS\_HS to remove the unused files from the external storage. By default, the job is enabled for STORETYPE\_AMAZONS3 and is disabled for STORETYPE\_TAPE. If the ENABLECLEANUPONDELETE property is set to TRUE, the job is enabled; if the property is set to FALSE, the job is disabled. If enabled, the job runs at an interval of one hour by default. The DBMS\_SCHEDULER package can be used to modify the schedule. The name of the job can be obtained by querying USER\_DBFS\_HS\_FIXED\_PROPERTIES for prop\_name = 'DELJOB\_NAME'.

#### Examples

##### Format

The format of wallet\_path in Windows is, for example:

```
file:c:\WINNT\Profiles\\WALLETS
```

The format of wallet\_path in UNIX or Linux is, for example:

```
file:/home/username/wallets
```

## 55.5.12 STOREPUSH Procedure

This procedure pushes locally staged data to the remote storage.

### Syntax

```
DBMS_DBFS_HS.STOREPUSH (  
    store_name    IN      VARCHAR2,  
    path          IN      VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 55-17 STOREPUSH Procedure Parameters**

| Parameter  | Description                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name | Name of store whose content the client writes from local cache to the external store                                                                           |
| path       | A non-mount qualified (without mount point) path within the store. By default, its value is <code>NULL</code> which corresponds to the root path of the store. |

### Usage Notes

- The Hierarchical Store caches the content files locally in database tables. When enough content is amassed in the cache to make it efficient to write to the external storage device (or the cache is completely filled), the Hierarchical Store creates a tarball out of the local content and writes these tarballs as files on the external device. The size of the tarball created by the Hierarchical Store is controlled by the store property `PROPNAME_OPTTARBALLSIZE`.
- When the amount of free space in the cache is such that the caching of a content file will push the space used above `cache_size`, the Hierarchical Store will internally call `STOREPUSH`. The `STOREPUSH` Procedure creates tarball(s) out of the existing dirty or modified content files in the cache and writes them out to the external device. A `STOREPUSH` call is not guaranteed to write all the dirty content from local cache to the external storage, since some files may be locked by other sessions.
- `STOREPUSH` has a built-in ability feature allowing it to automatically resume operation. If a `STOREPUSH` call is interrupted (say by a network outage) after it has transferred some tarballs to the external device, it can be restarted after the outage and will then resume transferring data from the point it was interrupted. In other words, work done before the outage is not lost. `STOREPUSH` can safely be restarted and the effect is such as if the outage never occurred.
- If this method successfully executes, its actions cannot be rolled back by the user.
- By default, when `path` is `NULL`, all files in the store are candidates for `STOREPUSH`. If `path` has a valid input value, all files which are under the namespace of given `path` are written from the local cache to the external store. If a given `path` is an existing file, it is pushed out again to the remote store.

# DBMS\_DBFS\_SFS

The `DBMS_DBFS_SFS` package provides an interface to operate a SecureFile-based store (SFS) for the content interface described in the `DBMS_DBFS_CONTENT` package.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_DBFS\\_SFS Subprograms](#)

## See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide*

## 56.1 DBMS\_DBFS\_SFS Overview

The `DBMS_DBFS_SFS` package is a sample implementation of a package that implements and extends the `DBMS_DBFS_CONTENT_SPI` interface. It provides a POSIX-compliant file system stored in the RDBMS.

## 56.2 DBMS\_DBFS\_SFS Security Model

The `DBMS_DBFS_SFS` package runs with `AUTHID CURRENT_USER`.

## 56.3 DBMS\_DBFS\_SFS Constants

The `DBMS_DBFS_SFS` package uses the constants shown in the following tables.

## Note:

Oracle has deprecated the older encryptions and hashing algorithms. The deprecated algorithms for `DBMS_CRYPTO` and native network encryption include MD4, MD5, DES, 3DES, and RC4-related algorithms as well as 3DES for Transparent Data Encryption (TDE). Removing older, less secure cryptography algorithms prevents accidental use of these algorithms. To meet your security requirements, Oracle recommends that you use more modern cryptography algorithms, such as the Advanced Encryption Standard (AES).

- [Table 56-3](#)
- [Table 56-4](#)

**Table 56-1 DBMS\_DBFS\_SFS Constants - Compression Levels**

| Constant            | Type         | Value    | Description                                  |
|---------------------|--------------|----------|----------------------------------------------|
| COMPRESSION_DEFAULT | VARCHAR2(32) | ' '      | Use the default SecureFile compression level |
| COMPRESSION_LOW     | VARCHAR2(32) | 'LOW'    | Use compression level 'LOW'                  |
| COMPRESSION_MEDIUM  | VARCHAR2(32) | 'MEDIUM' | Use compression level 'MEDIUM'               |
| COMPRESSION_HIGH    | VARCHAR2(32) | 'HIGH'   | Use compression level 'HIGH'                 |

**Table 56-2 DBMS\_DBFS\_SFS Constants - Used by the encryption Parameter**

| Constant           | Type         | Value    | Description                                     |
|--------------------|--------------|----------|-------------------------------------------------|
| ENCRYPTION_DEFAULT | VARCHAR2(32) | ' '      | Use the default SecureFile encryption algorithm |
| ENCRYPTION_AES128  | VARCHAR2(32) | 'AES128' | Use encryption AES 128 bit                      |
| ENCRYPTION_AES192  | VARCHAR2(32) | 'AES192' | Use encryption AES 192 bit                      |
| ENCRYPTION_AES256  | VARCHAR2(32) | 'AES256' | Use encryption AES 256 bit                      |

**Table 56-3 DBMS\_DBFS\_SFS Constants - Used by the npartitions Parameter**

| Constant           | Type    | Value | Description              |
|--------------------|---------|-------|--------------------------|
| DEFAULT_PARTITIONS | INTEGER | 16    | Default to 16 partitions |

**Table 56-4 DBMS\_DBFS\_SFS Constants - Used by the partition\_key Parameter**

| Constant          | Type    | Value | Description                                       |
|-------------------|---------|-------|---------------------------------------------------|
| PARTITION_BY_ITEM | INTEGER | 1     | Use a hash of the item name for the partition key |
| PARTITION_BY_PATH | INTEGER | 2     | Use a hash of the path name for the partition key |
| PARTITION_BY_GUID | INTEGER | 3     | Use a hash of the GUID as the partition key       |

## 56.4 Summary of DBMS\_DBFS\_SFS Subprograms

This table lists and describes the DBMS\_DBFS\_SFS Package subprograms.

**Table 56-5 DBMS\_DBFS\_SFS Package Subprograms**

| Subprogram                                 | Description                           |
|--------------------------------------------|---------------------------------------|
| <a href="#">CREATEFILESYSTEM Procedure</a> | Creates a file system store           |
| <a href="#">CREATESTORE Procedure</a>      | Creates a new DBFS SFS store          |
| <a href="#">DROPFILESYSTEM Procedures</a>  | Drops the DBFS SFS store              |
| <a href="#">INITFS Procedure</a>           | Initializes a POSIX file system store |

## 56.4.1 CREATEFILESYSTEM Procedure

This procedure creates a file system store.

### Syntax

```
DBMS_DBFS_SFS.CREATEFILESYSTEM (
  store_name          IN      VARCHAR2,
  schema_name         IN      VARCHAR2  DEFAULT NULL,
  tbl_name            IN      VARCHAR2  DEFAULT NULL,
  tbl_tbs             IN      VARCHAR2  DEFAULT NULL,
  lob_tbs             IN      VARCHAR2  DEFAULT NULL,
  use_bf              IN      BOOLEAN   DEFAULT FALSE,
  properties          IN      DBMS_DBFS_CONTENT_PROPERTIES_T DEFAULT NULL,
  create_only         IN      BOOLEAN   FALSE,
  use_objects         IN      BOOLEAN   DEFAULT FALSE,
  with_grants         IN      BOOLEAN   DEFAULT FALSE,
  do_dedup            IN      BOOLEAN   DEFAULT FALSE,
  do_compress         IN      BOOLEAN   DEFAULT FALSE,
  compression        IN      VARCHAR2  DEFAULT COMPRESSION_DEFAULT,
  do_encrypt          IN      BOOLEAN   DEFAULT FALSE,
  encryption         IN      VARCHAR2  DEFAULT ENCRYPTION_DEFAULT,
  do_partition        IN      BOOLEAN   DEFAULT FALSE,
  npartitions         IN      NUMBER    DEFAULTDEFAULT_PARTITIONS,
  partition_key       IN      NUMBER    DEFAULT PARTITION_BY_ITEM,
  partition_guidi     IN      BOOLEAN   DEFAULT FALSE,
  partition_pathi     IN      BOOLEAN   DEFAULT FALSE,
  partition_prop      IN      BOOLEAN   DEFAULT TRUE);
```

### Parameters

**Table 56-6 CREATEFILESYSTEM Procedure Parameters**

| Parameter   | Description                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| store_name  | Name of store                                                                                                                     |
| schema_name | Schema for the store, defaulting to the current schema                                                                            |
| tbl_name    | Table for store entries. If not specified, an internally generated name is used.                                                  |
| tbl_tbs     | Tablespace for the store, defaulting to the schema's default tablespace                                                           |
| lob_tbs     | Tablespace in which to create the LOB segment. It defaults to the user's default tablespace.                                      |
| use_bf      | If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used.                                                             |
| properties  | Table of (name, value, typecode) tuples used to configure the store properties. Currently no such properties are defined or used. |

**Table 56-6 (Cont.) CREATEFILESYSTEM Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| create_only     | If TRUE, the file system is created, but not registered with the current user                                                                                                                                                                                                                                    |
| use_objects     | If TRUE, a single base-table with an object-type column (using a nested table) is created to backup the new file system. Otherwise, a pair of (parent, child) tables is used to backup the file system. In both cases, the object type nested table or the child table is used only for user-defined properties. |
| with_grants     | If TRUE, DML and query access permissions are granted to the DBFS_ROLE as part of creating the file system. Otherwise, explicit grants (or existing permissions) are required to access the file system.                                                                                                         |
| do_dedup        | If TRUE, do deduplication the underlying SecureFile column                                                                                                                                                                                                                                                       |
| do_compress     | If TRUE, do compression the underlying SecureFile column                                                                                                                                                                                                                                                         |
| compression     | Compression algorithm to use (see <a href="#">Table 56-1</a> )                                                                                                                                                                                                                                                   |
| do_encrypt      | If TRUE, encrypt the underlying SecureFile column                                                                                                                                                                                                                                                                |
| encryption      | encryption algorithm to use (see <a href="#">Table 56-2</a> )                                                                                                                                                                                                                                                    |
| do_partition    | If TRUE, partition the table used for storage                                                                                                                                                                                                                                                                    |
| npartitions     | Number of partitions to create for the table (see <a href="#">Table 56-3</a> ).                                                                                                                                                                                                                                  |
| partition_key   | How to partition the table: by item name, by path name, or by GUID (see <a href="#">Table 56-4</a> ).                                                                                                                                                                                                            |
| partition_guidi | If TRUE, build an index on GUID                                                                                                                                                                                                                                                                                  |
| partition_pathi | If TRUE, build an index on path name                                                                                                                                                                                                                                                                             |
| partition_prop  | If TRUE, partition the properties table                                                                                                                                                                                                                                                                          |

**Usage Notes**

The procedure executes like a DDL in that it auto-commits before and after its execution.

## 56.4.2 CREATESTORE Procedure

This procedure creates a new DBFS SFS store owned by the invoking session user.

**Syntax**

```
DBMS_DBFS_SFS.CREATESTORE (
    store_name      IN      VARCHAR2,
    tbl_name        IN      VARCHAR2  DEFAULT NULL,
    tbs_name        in      VARCHAR2  DEFAULT NULL,
    use_bf          in      BOOLEAN   DEFAULT FALSE,
    stgopts         in      VARCHAR2  DEFAULT '');
```

**Parameters****Table 56-7 CREATESTORE Procedure Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

**Table 56-7 (Cont.) CREATESTORE Procedure Parameters**

| Parameter  | Description                                                           |
|------------|-----------------------------------------------------------------------|
| store_type | STORETYPE_TAPE or STORETYPE_AMAZONS3                                  |
| tbl_name   | Placeholder for the store content cached in database                  |
| tbs_name   | Named tablespace                                                      |
| use_bf     | If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used. |
| stgopts    | Currently non-operational, reserved for future use                    |

## 56.4.3 DROPFILESYSTEM Procedures

This procedure drops the DBFS SFS store, purging all dictionary information associated with the store, and dropping the underlying file system table.

### Syntax

```
DBMS_DBFS_SFS.DROPFILESYSTEM (
    schema_name    IN    VARCHAR2 DEFAULT NULL,
    tbl_name       IN    INTEGER);
```

```
DBMS_DBFS_SFS.DROPFILESYSTEM (
    store_name     IN    VARCHAR2);
```

### Parameters

**Table 56-8 DROPFILESYSTEM Procedure Parameters**

| Parameter   | Description        |
|-------------|--------------------|
| schema_name | Name of schema     |
| tbl_name    | Name of tablespace |
| store_name  | Name of store path |

### Usage Notes

- If the specified store table is registered by the current user, it will be unregistered from the content interface described in the `DBMS_DBFS_CONTENT` package and the POSIX metadata tables.
- Subsequent to unregistration, an attempt will be made to store table(s). This operation may fail if other users are currently using this store table.
- The user attempting a drop of the tables underlying the store must actually have the privileges to complete the drop operation (either as the owner of the tables, or as a sufficiently privileged user for cross-schema operations).
- The procedure executes like a DDL in that it auto-commits before and after its execution.

## 56.4.4 INITFS Procedure

This procedure initialize a POSIX file system store. The table associated with the POSIX file system store `store_name` is truncated and reinitialized with a single "root" directory entry.

### Syntax

```
DBMS_DBFS_SFS.INITFS (  
    store_name      IN      VARCHAR2);
```

### Parameters

**Table 56-9** INITFS Procedure Parameters

| Parameter               | Description   |
|-------------------------|---------------|
| <code>store_name</code> | Name of store |

### Usage Notes

The procedure executes like a DDL in that it auto-commits before and after its execution.

## DBMS\_DDL

This package provides access to some SQL data definition language (DDL) statements from stored procedures. It also provides special administration operations that are not available as Data Definition Language statements (DDLs).

This chapter contains the following topics:

- [Deprecated Subprograms](#)
- [Security Model](#)
- [Operational Notes](#)
- [Summary of DBMS\\_DDL Subprograms](#)

### 57.1 DBMS\_DDL Deprecated Subprograms

Oracle recommends that you do not use deprecated subprograms in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with release Oracle Database 10g:

- [ALTER\\_COMPILE Procedure](#)

### 57.2 DBMS\_DDL Security Model

This package runs with the privileges of the calling user, rather than the package owner SYS.

### 57.3 DBMS\_DDL Operational Notes

The `ALTER_COMPILE` procedure commits the current transaction, performs the operation, and then commits again.

### 57.4 Summary of DBMS\_DDL Subprograms

This table lists the `DBMS_DDL` subprograms in alphabetical order and briefly describes them.

**Table 57-1 DBMS\_DDL Package Subprograms**

| Subprogram                                              | Description                |
|---------------------------------------------------------|----------------------------|
| <a href="#">ALTER_COMPILE Procedure</a>                 | Compiles the PL/SQL object |
| <a href="#">ALTER_TABLE_NOT_REFERENCEABLE Procedure</a> | Reorganizes object tables  |
| <a href="#">ALTER_TABLE_REFERENCEABLE Procedure</a>     | Reorganizes object tables  |

Table 57-1 (Cont.) DBMS\_DDL Package Subprograms

| Subprogram                                             | Description                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_WRAPPED Procedures</a>              | Takes as input a single CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body, generates a CREATE OR REPLACE statement with the PL/SQL source text obfuscated and executes the generated statement |
| <a href="#">IS_TRIGGER_FIRE_ONCE Function</a>          | Returns TRUE if the specified DML or DDL trigger is set to fire once. Otherwise, returns FALSE                                                                                                                                                                                                         |
| <a href="#">SET_TRIGGER_FIRING_PROPERTY Procedures</a> | Sets the specified DML or DDL trigger's firing property                                                                                                                                                                                                                                                |
| <a href="#">WRAP Functions</a>                         | Takes as input a CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a CREATE OR REPLACE statement where the text of the PL/SQL unit has been obfuscated                             |

## 57.4.1 ALTER\_COMPILE Procedure

This procedure is equivalent to the SQL statement: ALTER PROCEDURE | FUNCTION | PACKAGE [<schema>.] <name> COMPILE [BODY]

### Note:

This procedure is deprecated in Oracle Database 10g Release 2 (10.2). While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the DDL equivalent in a dynamic SQL statement.

### Syntax

```
DBMS_DDL.ALTER_COMPILE (
    type          VARCHAR2,
    schema        VARCHAR2,
    name          VARCHAR2,
    reuse_settings BOOLEAN := FALSE);
```

### Parameters

Table 57-2 ALTER\_COMPILE Procedure Parameters

| Parameter      | Description                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| type           | Must be either PROCEDURE, FUNCTION, PACKAGE, PACKAGE BODY or TRIGGER                                                                      |
| schema         | Schema name<br>If NULL, then use current schema (case-sensitive)                                                                          |
| name           | Name of the object (case-sensitive)                                                                                                       |
| reuse_settings | Indicates whether the session settings in the objects should be reused, or whether the current session settings should be adopted instead |

## Exceptions

**Table 57-3 ALTER\_COMPILE Procedure Exceptions**

| Exception  | Description                                                                                        |
|------------|----------------------------------------------------------------------------------------------------|
| ORA-20000: | Insufficient privileges or object does not exist                                                   |
| ORA-20001: | Remote object, cannot compile                                                                      |
| ORA-20002: | Bad value for object type: should be either PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, or TRIGGER |

## 57.4.2 ALTER\_TABLE\_NOT\_REFERENCEABLE Procedure

This procedure alters the given object table `table_schema.table_name` so it becomes not the default referenceable table for the schema `affected_schema`.

This is equivalent to SQL:

```
ALTER TABLE [<table_schema>.<table_name>] NOT REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

### Syntax

```
DBMS_DDL.ALTER_TABLE_NOT_REFERENCEABLE (  
    table_name      IN          VARCHAR2,  
    table_schema    IN  DEFAULT  NULL,  
    affected_schema IN  DEFAULT  NULL);
```

### Parameters

**Table 57-4 ALTER\_TABLE\_NOT\_REFERENCEABLE Procedure Parameters**

| Parameter                    | Description                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>table_name</code>      | Name of the table to be altered. Cannot be a synonym. Must not be NULL. Case sensitive.                     |
| <code>table_schema</code>    | Name of the schema owning the table to be altered. If NULL then the current schema is used. Case sensitive. |
| <code>affected_schema</code> | Name of the schema affected by this alteration. If NULL then the current schema is used. Case sensitive.    |

### Usage Notes

This procedure simply reverts for the affected schema to the default table referenceable for PUBLIC; that is., it simply undoes the previous `ALTER_TABLE_REFERENCEABLE` call for this specific schema. The affected schema must a particular schema (cannot be PUBLIC).

The user that executes this procedure must own the table (that is, the schema is the same as the user), and the affected schema must be the same as the user.

If the user executing this procedure has `ALTER ANY TABLE` and `SELECT ANY TABLE` and `DROP ANY TABLE` privileges, the user doesn't have to own the table and the affected schema can be any valid schema.

## 57.4.3 ALTER\_TABLE\_REFERENCEABLE Procedure

This procedure alters the given object table `table_schema.table_name` so it becomes the referenceable table for the given schema `affected_schema`.

This is equivalent to SQL:

```
ALTER TABLE [<table_schema>.<table_name>] REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

### Syntax

```
DBMS_DDL.ALTER_TABLE_REFERENCEABLE
  table_name      IN  VARCHAR2,
  table_schema    IN  DEFAULT  NULL,
  affected_schema IN  DEFAULT  NULL);
```

### Parameters

**Table 57-5 ALTER\_TABLE\_REFERENCEABLE Procedure Parameters**

| Parameter                    | Description                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>table_name</code>      | Name of the table to be altered. Cannot be a synonym. Must not be <code>NULL</code> . Case sensitive.                    |
| <code>table_schema</code>    | Name of the schema owning the table to be altered. If <code>NULL</code> then the current schema is used. Case sensitive. |
| <code>affected_schema</code> | Name of the schema affected by this alteration. If <code>NULL</code> then the current schema is used. Case sensitive.    |

### Usage Notes

When you create an object table, it automatically becomes referenceable, unless you use the `OID AS` clause when creating the table. The `OID AS` clause makes it possible for you to create an object table and to assign to the new table the same `EOID` as another object table of the same type. After you create a new table using the `OID AS` clause, you end up with two object table with the same `EOID`; the new table is not referenceable, the original one is. All references that used to point to the objects in the original table still reference the same objects in the same original table.

If you execute this procedure on the new table, it makes the new table the referenceable table replacing the original one; thus, those references now point to the objects in the new table instead of the original table.

## 57.4.4 CREATE\_WRAPPED Procedures

The procedure takes as input a single `CREATE OR REPLACE` statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body. It then generates a `CREATE OR REPLACE` statement with the PL/SQL source text

obfuscated and executes the generated statement. In effect, this procedure bundles together the operations of wrapping the text and creating the PL/SQL unit.

### See Also:

[WRAP Functions](#)

This procedure has 3 overloads. Each of the three functions provides better performance than using a combination of individual [WRAP Functions](#) and `DBMS_SQL.PARSE` (or `EXECUTE IMMEDIATE`) calls. The different functionality of each form of syntax is presented with the definition.

### Syntax

Is a shortcut for `EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP(ddl)`:

```
DBMS_DDL.CREATE_WRAPPED (
    ddl      VARCHAR2);
```

Is a shortcut for `DBMS_SQL.PARSE(cursor, SYS.DBMS_DDL.WRAP (input, lb, ub))`:

```
DBMS_DDL.CREATE_WRAPPED (
    ddl      DBMS_SQL.VARCHAR2A,
    lb       PLS_INTEGER,
    ub       PLS_INTEGER);
```

Is a shortcut for `DBMS_SQL.PARSE(cursor, SYS.DBMS_DDL.WRAP (input, lb, ub))`:

```
DBMS_DDL.CREATE_WRAPPED (
    ddl      DBMS_SQL.VARCHAR2S,
    lb       PLS_INTEGER,
    ub       PLS_INTEGER);
```

### Parameters

**Table 57-6 CREATE\_WRAPPED Procedure Parameters**

| Parameter | Description                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ddl       | A CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body |
| lb        | Lower bound for indices in the string table that specify the CREATE OR REPLACE statement                                                                    |
| ub        | Upper bound for indices in the string table that specify the CREATE OR REPLACE statement.                                                                   |

### Usage Notes

- The CREATE OR REPLACE statement is executed with the privileges of the user invoking `DBMS_DDL.CREATE_WRAPPED`.
- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name `SYS.DBMS_DDL` to avoid the possibility that the name `DBMS_DDL` is captured by a locally-defined unit or by redefining the `DBMS_DDL` public synonym.

- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL `wrap` utility accepts a entire SQL\*Plus file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL's dynamic SQL interfaces (`EXECUTE IMMEDIATE` and `DBMS_SQL.PARSE`). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL\*Plus `"/"` termination character), both the [CREATE\\_WRAPPED Procedures](#) and the [WRAP Functions](#) require input to be a single unit.

### Exceptions

ORA-24230: If the input is not a `CREATE` OR `REPLACE` statement specifying a PL/SQL unit, exception `DBMS_DDL.MALFORMED_WRAP_INPUT` is raised.

### Examples

```
DECLARE
    ddl VARCHAR2(32767);
BEGIN
    ddl := GENERATE_PACKAGE(...);
    SYS.DBMS_DDL.CREATE_WRAPPED(ddl); -- Instead of EXECUTE IMMEDIATE ddl
END;
```

## 57.4.5 IS\_TRIGGER\_FIRE\_ONCE Function

This function returns `TRUE` if the specified DML or DDL trigger is set to fire once. Otherwise, it returns `FALSE`.

A fire once trigger fires in a user session but does not fire in the following cases:

- For changes made by a Streams apply process
- For changes made by executing one or more Streams apply errors using the `EXECUTE_ERROR` or `EXECUTE_ALL_ERRORS` procedure in the `DBMS_APPLY_ADM` package
- For changes made by a Logical Standby apply process

#### Note:

Only DML and DDL triggers can be fire once. All other types of triggers always fire.

#### See Also:

["SET\\_TRIGGER\\_FIRING\\_PROPERTY Procedures"](#)

### Syntax

```
DBMS_DDL.IS_TRIGGER_FIRE_ONCE
    trig_owner      IN  VARCHAR2,
    trig_name       IN  VARCHAR2)
RETURN BOOLEAN;
```

## Parameters

**Table 57-7 IS\_TRIGGER\_FIRE\_ONCE Function Parameters**

| Parameter  | Description       |
|------------|-------------------|
| trig_owner | Schema of trigger |
| trig_name  | Name of trigger   |

## 57.4.6 SET\_TRIGGER\_FIRING\_PROPERTY Procedures

This procedure sets the specified DML or DDL trigger's firing property whether or not the property is set for the trigger.

Use this procedure to control a DML or DDL trigger's firing property for changes:

- Applied by a Streams apply process
- Made by executing one or more Streams apply errors using the `EXECUTE_ERROR` or `EXECUTE_ALL_ERRORS` procedure in the `DBMS_APPLY_ADM` package.
- Applied by a Logical Standby apply process

### Syntax

```
DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (  
    trig_owner      IN VARCHAR2,  
    trig_name       IN VARCHAR2,  
    fire_once       IN BOOLEAN);
```

```
DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (  
    trig_owner      IN VARCHAR2,  
    trig_name       IN VARCHAR2,  
    property        IN INTEGER,  
    setting         IN BOOLEAN);
```

## Parameters

**Table 57-8 SET\_TRIGGER\_FIRING\_PROPERTY Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trig_owner | Schema of the trigger to set                                                                                                                                                                                                                                                                                                                                                                                            |
| trig_name  | Name of the trigger to set                                                                                                                                                                                                                                                                                                                                                                                              |
| fire_once  | <ul style="list-style-type: none"><li>• If <code>TRUE</code>, the trigger is set to fire once. By default, the <code>fire_once</code> parameter is set to <code>TRUE</code> for DML and DDL triggers.</li><li>• If <code>FALSE</code>, the trigger is set to always fire unless <code>apply_server_only</code> property is set to <code>TRUE</code>, which overrides <code>fire_once</code> property setting.</li></ul> |
| property   | <ul style="list-style-type: none"><li>• <code>DBMS_DDL.fire_once</code> to set the <code>fire_once</code> property of the trigger</li><li>• <code>DBMS_DDL.apply_server_only</code> to indicate whether trigger fires only in the context of SQL apply processes maintaining a logical standby database or Streams apply processes</li></ul>                                                                            |
| setting    | Value of property being set                                                                                                                                                                                                                                                                                                                                                                                             |

## Usage Notes

DML triggers created on a table have their fire-once property set to `TRUE`. In this case, the triggers only fire when the table is modified by an user process, and they are automatically disabled inside Oracle processes maintaining either a logical standby database (SQL Apply) or Oracle processes doing replication (Streams Apply) processes, and thus do not fire when a SQL Apply or a Streams Apply process modifies the table. There are two ways for a user to fire a trigger as a result of SQL Apply or a Streams Apply process making a change to a maintained table: (a) setting the fire-once property of a trigger to `FALSE`, which allows it fire both in the context of a user process or a SQL or Streams Apply process, or (b) by setting the apply-server-only property to `TRUE` and thus making the trigger fire only in the context of a SQL Apply or a Streams Apply process and not in the context of a user process.

- `FIRE_ONCE=TRUE, APPLY_SERVER_ONLY=FALSE`

This is the default property setting for a DML trigger. The trigger only fires when user process modifies the base table.

- `FIRE_ONCE=TRUE or FALSE, APPLY_SERVER_ONLY=TRUE`

The trigger only fires when SQL Apply or Streams Apply process modifies the base table. The trigger does not fire when a user process modifies the base table. Thus the apply-server-only property overrides the fire-once property of a trigger.

### Note:

- If you dequeue an error transaction from the error queue and execute it without using the `DBMS_APPLY_ADM` package, then relevant changes resulting from this execution cause a trigger to fire, regardless of the trigger firing property.
- Only DML and DDL triggers can be fire once. All other types of triggers always fire.

## 57.4.7 WRAP Functions

This function takes as input a single `CREATE OR REPLACE` statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a `CREATE OR REPLACE` statement where the text of the PL/SQL unit has been obfuscated.

The function has 3 overloads to allow for the different ways in which DDL statements can be generated dynamically and presented to `DBMS_SQL` or `EXECUTE IMMEDIATE`. The different functionality of each form of syntax is presented with the definition.

### See Also:

[CREATE\\_WRAPPED Procedures](#)

## Syntax

Provides basic functionality:

```
DBMS_DDL.WRAP (
    ddl      VARCHAR2)
RETURN VARCHAR2;
```

Provides the same functionality as the first form, but allows for larger inputs. This function is intended to be used with the [PARSE Procedures](#) in the [DBMS\\_SQL](#) package and its argument list follows the convention of [DBMS\\_SQL.PARSE](#):

```
DBMS_DDL.WRAP (
    ddl      DBMS_SQL.VARCHAR2S,
    lb       PLS_INTEGER,
    ub       PLS_INTEGER)
RETURN DBMS_SQL.VARCHAR2S;
```

Provides the same functionality as the second form and is provided for compatibility with multiple forms of the [PARSE Procedures](#) in the [DBMS\\_SQL](#) package:

```
DBMS_DDL.WRAP (
    ddl      DBMS_SQL.VARCHAR2A,
    lb       PLS_INTEGER,
    ub       PLS_INTEGER)
RETURN DBMS_SQL.VARCHAR2A;
```

## Parameters

**Table 57-9 WRAP Function Parameters**

| Parameter | Description                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ddl       | A <code>CREATE</code> OR <code>REPLACE</code> statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body |
| lb        | Lower bound for indices in the string table that specify the <code>CREATE</code> OR <code>REPLACE</code> statement                                                                    |
| ub        | Upper bound for indices in the string table that specify the <code>CREATE</code> OR <code>REPLACE</code> statement.                                                                   |

## Return Values

A `CREATE` OR `REPLACE` statement with the text obfuscated. In the case of the second and third form, the return value is a table of strings that need to be concatenated in order to construct the `CREATE` OR `REPLACE` string containing obfuscated source text.

## Usage Notes

- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name `SYS.DBMS_DDL` to avoid the possibility that the name `DBMS_DDL` is captured by a locally-defined unit or by redefining the `DBMS_DDL` public synonym.
- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL `wrap` utility accepts a full SQL file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL's dynamic SQL interfaces (`EXECUTE IMMEDIATE` and `DBMS_SQL.PARSE`). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL\*Plus `"/` termination character), both the [CREATE\\_WRAPPED Procedures](#) and the [WRAP Functions](#) require input to be a single unit.

## Exceptions

ORA-24230: If the input is not a CREATE OR REPLACE statement specifying a PL/SQL unit, exception DBMS\_DDL.MALFORMED\_WRAP\_INPUT is raised.

## Examples

```
DECLARE
    ddl VARCHAR2(32767);
BEGIN
    ddl := GENERATE_PACKAGE(...);
EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP(ddl); -- Instead of EXECUTE IMMEDIATE ddl
END;
```

# DBMS\_DEBUG

`DBMS_DEBUG` is deprecated. Use `DBMS_DEBUG_JDWP` instead.

See [DBMS\\_DEBUG\\_JDWP](#) for more information.

`DBMS_DEBUG` is a PL/SQL interface to the PL/SQL debugger layer, Probe, in the Oracle server.

This package is primarily intended to implement server-side debuggers and it provides a way to debug server-side PL/SQL program units.

**Note:**

The term *program unit* refers to a PL/SQL program of any type (procedure, function, package, package body, trigger, anonymous block, object type, or object type body).

This chapter contains the following topics:

- [Overview](#)
- [Constants](#)
- [Variables](#)
- [Exceptions](#)
- [Operational Notes](#)
- [Data Structures](#)
- [Summary of DBMS\\_DEBUG Subprograms](#)

## 58.1 DBMS\_DEBUG Overview

To debug server-side code, you must have two database sessions: one session to run the code in debug mode (the target session), and a second session to supervise the target session (the debug session).

The target session becomes available for debugging by making initializing calls with `DBMS_DEBUG`. This marks the session so that the PL/SQL interpreter runs in debug mode and generates debug events. As debug events are generated, they are posted from the session. In most cases, debug events require return notification: the interpreter pauses awaiting a reply.

Meanwhile, the debug session must also initialize itself using `DBMS_DEBUG`. This tells it which target session to supervise. The debug session may then call entry points in `DBMS_DEBUG` to read events that were posted from the target session and to communicate with the target session.

The following subprograms are run in the target session (the session that is to be debugged):

- [SYNCHRONIZE Function](#)
- [DEBUG\\_ON Procedure](#)

- [DEBUG\\_OFF Procedure](#)

DBMS\_DEBUG does not provide an interface to the PL/SQL compiler, but it does depend on debug information optionally generated by the compiler. Without debug information, it is not possible to examine or modify the values of parameters or variables.

## 58.2 DBMS\_DEBUG Constants

A breakpoint status may have the following value: `breakpoint_status_unused`—breakpoint is not in use.

Otherwise, the status is a mask of the following values:

- `breakpoint_status_active`—a line breakpoint
- `breakpoint_status_disabled`—breakpoint is currently disabled
- `breakpoint_status_remote`—a shadow breakpoint (a local representation of a remote breakpoint)

## 58.3 DBMS\_DEBUG Variables

The DBMS\_DEBUG uses the variables shown in the following table.

**Table 58-1 DBMS\_DEBUG Variables**

| Variable                     | Description                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>default_timeout</code> | The timeout value (used by both sessions). The smallest possible timeout is 1 second. If this value is set to 0, then a large value (3600) is used. |

## 58.4 DBMS\_DEBUG Exceptions

These values are returned by the various functions called in the debug session (`SYNCHRONIZE`, `CONTINUE`, `SET_BREAKPOINT`, and so on). If PL/SQL exceptions worked across client/server and server/server boundaries, then these would all be exceptions rather than error codes.

**Table 58-2 DBMS\_DEBUG Exceptions**

| Status               | Description        |
|----------------------|--------------------|
| <code>success</code> | Normal termination |

Statuses returned by `GET_VALUE` and `SET_VALUE`:

**Table 58-3 DBMS\_DEBUG Exceptions Returned by GET\_VALUE and SET\_VALUE**

| Status                            | Description                                |
|-----------------------------------|--------------------------------------------|
| <code>error_bogus_frame</code>    | No such entrypoint on the stack            |
| <code>error_no_debug_info</code>  | Program was compiled without debug symbols |
| <code>error_no_such_object</code> | No such variable or parameter              |
| <code>error_unknown_type</code>   | Debug information is unreadable            |

**Table 58-3 (Cont.) DBMS\_DEBUG Exceptions Returned by GET\_VALUE and SET\_VALUE**

| Status               | Description                                                               |
|----------------------|---------------------------------------------------------------------------|
| error_indexed_table  | Returned by GET_VALUE if the object is a table, but no index was provided |
| error_illegal_index  | No such element exists in the collection                                  |
| error_nullcollection | Table is atomically NULL                                                  |
| error_nullvalue      | Value is NULL                                                             |

Statuses returned by SET\_VALUE:

**Table 58-4 DBMS\_DEBUG Exceptions Returned by SET\_VALUE**

| Status                | Description                        |
|-----------------------|------------------------------------|
| error_illegal_value   | Constraint violation               |
| error_illegal_null    | Constraint violation               |
| error_value_malformed | Unable to decipher the given value |
| error_other           | Some other error                   |
| error_name_incomplete | Name did not resolve to a scalar   |

Statuses returned by the breakpoint functions:

**Table 58-5 Statuses Returned by the Breakpoint Functions**

| Status                | Description                                                                   |
|-----------------------|-------------------------------------------------------------------------------|
| error_no_such_breakpt | No such breakpoint                                                            |
| error_idle_breakpt    | Cannot enable or disable an unused breakpoint                                 |
| error_bad_handle      | Unable to set breakpoint in given program (nonexistent or security violation) |

General error codes (returned by many of the DBMS\_DEBUG subprograms):

**Table 58-6 DBMS\_DEBUG Subprograms Error Codes**

| Status              | Description                                                               |
|---------------------|---------------------------------------------------------------------------|
| error_unimplemented | Functionality is not yet implemented                                      |
| error_deferred      | No program running; operation deferred                                    |
| error_exception     | An exception was raised in the DBMS_DEBUG or Probe packages on the server |
| error_communication | Some error other than a timeout occurred                                  |
| error_timeout       | Timeout occurred                                                          |

**Table 58-7 illegal\_init Exceptions**

| Exception    | Description                             |
|--------------|-----------------------------------------|
| illegal_init | DEBUG_ON was called prior to INITIALIZE |

The following exceptions are raised by procedure SELF\_CHECK:

**Table 58-8 SELF\_CHECK Procedure Exceptions**

| Exception              | Description                       |
|------------------------|-----------------------------------|
| pipe_creation_failure  | Could not create a pipe           |
| pipe_send_failure      | Could not write data to the pipe  |
| pipe_receive_failure   | Could not read data from the pipe |
| pipe_datatype_mismatch | Datatype in the pipe was wrong    |
| pipe_data_error        | Data got garbled in the pipe      |

## 58.5 DBMS\_DEBUG Operational Notes

There are two ways to ensure that debug information is generated: through a session switch, or through individual recompilation.

To set the session switch, enter the following statement:

```
ALTER SESSION SET PLSQL_DEBUG = true;
```

This instructs the compiler to generate debug information for the remainder of the session. It does not recompile any existing PL/SQL.

To generate debug information for existing PL/SQL code, use one of the following statements (the second recompiles a package or type body):

```
ALTER [PROCEDURE | FUNCTION | PACKAGE | TRIGGER | TYPE] <name> COMPILE DEBUG;  
ALTER [PACKAGE | TYPE] <name> COMPILE DEBUG BODY;
```

[Figure 58-1](#) and [Figure 58-2](#) illustrate the flow of operations in the session to be debugged and in the debugging session.

**Figure 58-1 Target Session**

### Control of the Interpreter

The interpreter pauses execution at the following times:

1. At startup of the interpreter so any deferred breakpoints may be installed prior to execution.
2. At any line containing an enabled breakpoint.
3. At any line where an *interesting* event occurs. The set of interesting events is specified by the flags passed to `DBMS_DEBUG.CONTINUE` in the `breakflags` parameter.

## Session Termination

There is no event for session termination. Therefore, it is the responsibility of the debug session to check and make sure that the target session has not ended. A call to `DBMS_DEBUG.SYNCHRONIZE` after the target session has ended causes the debug session to hang until it times out.

## Deferred Operations

The diagram suggests that it is possible to set breakpoints prior to having a target session. This is true. In this case, Probe caches the breakpoint request and transmits it to the target session at first synchronization. However, if a breakpoint request is deferred in this fashion, then:

- `SET_BREAKPOINT` does not set the breakpoint number (it can be obtained later from `SHOW_BREAKPOINTS` if necessary).
- `SET_BREAKPOINT` does not validate the breakpoint request. If the requested source line does not exist, then an error silently occurs at synchronization, and no breakpoint is set.

## Diagnostic Output

To debug Probe, there are *diagnostics* parameters to some of the calls in `DBMS_DEBUG`. These parameters specify whether to place diagnostic output in the RDBMS tracefile. If output to the RDBMS tracefile is disabled, these parameters have no effect.

## Common Debug Session Sections

- Common Section
- Target Session
- Debug Session Section

### Common Section

The following subprograms may be called in either the target or the debug session:

- [PROBE\\_VERSION Procedure](#)
- [SELF\\_CHECK Procedure](#)
- [SET\\_TIMEOUT Function](#)

### Target Session

The following subprograms may be called only in the target session:

- [INITIALIZE Function](#)
- [DEBUG\\_ON Procedure](#)
- [SET\\_TIMEOUT\\_BEHAVIOUR Procedure](#)
- [GET\\_TIMEOUT\\_BEHAVIOUR Function](#)

### Debug Session Section

The following subprograms should be run in the debug session only:

- [ATTACH\\_SESSION Procedure](#)
- [SYNCHRONIZE Function](#)
- [SHOW\\_FRAME\\_SOURCE Procedure](#)

- [SHOW\\_SOURCE Procedures](#)
- [GET\\_MORE\\_SOURCE Procedure](#)
- [PRINT\\_BACKTRACE Procedure](#)
- [CONTINUE Function](#)
- [SET\\_BREAKPOINT Function](#)
- [DELETE\\_BREAKPOINT Function](#)
- [SET\\_OER\\_BREAKPOINT Function](#)
- [DELETE\\_OER\\_BREAKPOINT Function](#)
- [ENABLE\\_BREAKPOINT Function](#)
- [DISABLE\\_BREAKPOINT Function](#)
- [SHOW\\_BREAKPOINTS Procedures](#)
- [SET\\_VALUE Function](#)
- [GET\\_VALUE Function](#)
- [TARGET\\_PROGRAM\\_RUNNING Procedure](#)
- [DETACH\\_SESSION Procedure](#)
- [GET\\_RUNTIME\\_INFO Function](#)
- [PRINT\\_INSTANTIATIONS Procedure](#)
- [PING Procedure](#)
- [GET\\_LINE\\_MAP Function](#)
- [GET\\_RUNTIME\\_INFO Function](#)
- [GET\\_INDEXES Function](#)
- [EXECUTE Procedure](#)

### OER Breakpoints

Exceptions that are declared in PL/SQL programs are known as user-defined exceptions. In addition, there are Oracle Errors (OERs) that are returned from the Oracle kernel. To tie the two mechanisms together, PL/SQL provides the `exception_init` pragma that turns a user-defined exception into an OER, so that a PL/SQL handler may be used for it, and so that the PL/SQL engine can return OERs to the Oracle kernel. As of the current release, the only information available about an OER is its number. If two user-defined exceptions are `exception_init`'d to the same OER, they are indistinguishable.

### Namespaces

Program units on the server reside in different namespaces. When setting a breakpoint, specify the desired namespace.

1. `Namespace_cursor` contains cursors (anonymous blocks).
2. `Namespace_pgkspec_or_toplevel` contains:
  - Package specifications.
  - Procedures and functions that are not nested inside other packages, procedures, or functions.
  - Object types.

3. `Namespace_pkg_body` contains package bodies and type bodies.
4. `Namespace_trigger` contains triggers.

### Libunit Types

These values are used to disambiguate among objects in a given namespace. These constants are used in `PROGRAM_INFO` when Probe is giving a stack backtrace.

- `LibunitType_cursor`
- `LibunitType_procedure`
- `LibunitType_function`
- `LibunitType_package`
- `LibunitType_package_body`
- `LibunitType_trigger`
- `LibunitType_Unknown`

### Breakflags

These are values to use for the `breakflags` parameter to `CONTINUE`, in order to tell Probe what events are of interest to the client. These flags may be combined.

| Value                         | Description                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>break_next_line</code>  | Break at next source line (step over calls)                                                                                                                                                                                                                              |
| <code>break_any_call</code>   | Break at next source line (step into calls)                                                                                                                                                                                                                              |
| <code>break_any_return</code> | Break after returning from current entrypoint (skip over any entrypoints called from the current routine)                                                                                                                                                                |
| <code>break_return</code>     | Break the next time an entrypoint gets ready to return. (This includes entrypoints called from the current one. If interpreter is running <code>Proc1</code> , which calls <code>Proc2</code> , then <code>break_return</code> stops at the end of <code>Proc2</code> .) |
| <code>break_exception</code>  | Break when an exception is raised                                                                                                                                                                                                                                        |
| <code>break_handler</code>    | Break when an exception handler is executed                                                                                                                                                                                                                              |
| <code>abort_execution</code>  | Stop execution and force an 'exit' event as soon as <code>DBMS_DEBUG.CONTINUE</code> is called.                                                                                                                                                                          |

### Information Flags

These are flags which may be passed as the `info_requested` parameter to `SYNCHRONIZE`, `CONTINUE`, and `GET_RUNTIME_INFO`.

| Flag                            | Description                        |
|---------------------------------|------------------------------------|
| <code>info_getStackDepth</code> | Get the current depth of the stack |
| <code>info_getBreakpoint</code> | Get the breakpoint number          |
| <code>info_getLineinfo</code>   | Get program unit information       |

### Reasons for Suspension

After `CONTINUE` is run, the program either runs to completion or breaks on some line.

| Reason                      | Description                       |
|-----------------------------|-----------------------------------|
| reason_none                 | -                                 |
| reason_interpreter_starting | Interpreter is starting           |
| reason_breakpoint           | Hit a breakpoint                  |
| reason_enter                | Procedure entry                   |
| reason_return               | Procedure is about to return      |
| reason_finish               | Procedure is finished             |
| reason_line                 | Reached a new line                |
| reason_interrupt            | An interrupt occurred             |
| reason_exception            | An exception was raised           |
| reason_exit                 | Interpreter is exiting (old form) |
| reason_knl_exit             | Kernel is exiting                 |
| reason_handler              | Start exception-handler           |
| reason_timeout              | A timeout occurred                |
| reason_instantiate          | Instantiation block               |
| reason_abort                | Interpreter is aborting           |

## 58.6 DBMS\_DEBUG Data Structures

The `DBMS_DEBUG` package defines `RECORD` types and `TABLE` types.

### RECORD Types

- [BREAKPOINT\\_INFO Record Type](#)
- [PROGRAM\\_INFO Record Type](#)
- [RUNTIME\\_INFO Record Type](#)

### TABLE Types

- [BACKTRACE\\_TABLE Table Type](#)
- [BREAKPOINT\\_TABLE Table Type](#)
- [INDEX\\_TABLE Table Type](#)
- [VC2\\_TABLE Table Type](#)

### 58.6.1 BREAKPOINT\_INFO Record Type

This type gives information about a breakpoint, such as its current status and the program unit in which it was placed.

#### Syntax

```
TYPE breakpoint_info IS RECORD (  
    name          VARCHAR2(30),  
    owner         VARCHAR2(30),  
    dblink        VARCHAR2(30),
```

```

line#          BINARY_INTEGER,
libunittype    BINARY_INTEGER,
status         BINARY_INTEGER);

```

## Fields

**Table 58-9 BREAKPOINT\_INFO Fields**

| Field       | Description                                                     |
|-------------|-----------------------------------------------------------------|
| name        | Name of the program unit                                        |
| owner       | Owner of the program unit                                       |
| dblink      | Database link, if remote                                        |
| line#       | Line number                                                     |
| libunittype | NULL, unless this is a nested procedure or function             |
| status      | See <a href="#">Constants</a> for values of breakpoint_status_* |

## 58.6.2 PROGRAM\_INFO Record Type

The `PROGRAM_INFO` record type of the `DBMS_DEBUG` package specifies a program location. It is a line number in a program unit.

This is used for stack backtraces and for setting and examining breakpoints. The read-only fields are currently ignored by Probe for breakpoint operations. They are set by Probe only for stack backtraces.

## Syntax

```

TYPE program_info IS RECORD(
    -- The following fields are used when setting a breakpoint
    namespace    BINARY_INTEGER,
    name         VARCHAR2(30),
    owner        VARCHAR2(30),
    dblink       VARCHAR2(30),
    line#        BINARY_INTEGER,
    -- Read-only fields (set by Probe when doing a stack backtrace)
    libunittype  BINARY_INTEGER,
    entrypointname VARCHAR2(30));

```

## Fields

**Table 58-10 PROGRAM\_INFO Fields**

| Field       | Description                                                                             |
|-------------|-----------------------------------------------------------------------------------------|
| namespace   | See <a href="#">DBMS_DEBUG Operational Notes</a> for more information about namespaces. |
| name        | Name of the program unit                                                                |
| owner       | Owner of the program unit                                                               |
| dblink      | Database link, if remote                                                                |
| line#       | Line number                                                                             |
| libunittype | A read-only field, NULL, unless this is a nested procedure or function                  |

**Table 58-10 (Cont.) PROGRAM\_INFO Fields**

| Field          | Description                                                                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entrypointname | A read-only field, to disambiguate among objects that share the same namespace (for example, procedure and package specifications).<br>See <a href="#">DBMS_DEBUG Operational Notes</a> for more information about the libunit types. |

### 58.6.3 RUNTIME\_INFO Record Type

This type gives context information about the running program.

#### Syntax

```
TYPE runtime_info IS RECORD(  
    line#           BINARY_INTEGER,  
    terminated      binary_integer,  
    breakpoint      binary_integer,  
    stackdepth      BINARY_INTEGER,  
    interpreterdepth BINARY_INTEGER,  
    reason          BINARY_INTEGER,  
    program         program_info);
```

#### Fields

**Table 58-11 RUNTIME\_INFO Fields**

| Field            | Description                        |
|------------------|------------------------------------|
| line#            | Duplicate of program.line#         |
| terminated       | Whether the program has terminated |
| breakpoint       | Breakpoint number                  |
| stackdepth       | Number of frames on the stack      |
| interpreterdepth | [A reserved field]                 |
| reason           | Reason for suspension              |
| program          | Source location                    |

### 58.6.4 BACKTRACE\_TABLE Table Type

This type is used by PRINT\_BACKTRACE.

#### Syntax

```
TYPE backtrace_table IS TABLE OF program_info INDEX BY BINARY_INTEGER;
```

### 58.6.5 BREAKPOINT\_TABLE Table Type

This type is used by SHOW\_BREAKPOINTS.

#### Syntax

```
TYPE breakpoint_table IS TABLE OF breakpoint_info INDEX BY BINARY_INTEGER;
```

## 58.6.6 INDEX\_TABLE Table Type

This type is used by `GET_INDEXES` to return the available indexes for an indexed table.

### Syntax

```
TYPE index_table IS table of BINARY_INTEGER INDEX BY BINARY_INTEGER;
```

## 58.6.7 VC2\_TABLE Table Type

This type is used by `SHOW_SOURCE`.

### Syntax

```
TYPE vc2_table IS TABLE OF VARCHAR2(90) INDEX BY BINARY_INTEGER;
```

## 58.7 Summary of DBMS\_DEBUG Subprograms

This table lists the `DBMS_DEBUG` subprograms in alphabetical order and briefly describes them.

**Table 58-12 DBMS\_DEBUG Package Subprograms**

| Subprogram                                     | Description                                                                                    |
|------------------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">ATTACH_SESSION Procedure</a>       | Notifies the debug session about the target debugID                                            |
| <a href="#">CONTINUE Function</a>              | Continues execution of the target program                                                      |
| <a href="#">DEBUG_OFF Procedure</a>            | Turns debug-mode off                                                                           |
| <a href="#">DEBUG_ON Procedure</a>             | Turns debug-mode on                                                                            |
| <a href="#">DELETE_BREAKPOINT Function</a>     | Deletes a breakpoint                                                                           |
| <a href="#">DELETE_OER_BREAKPOINT Function</a> | Deletes an OER breakpoint                                                                      |
| <a href="#">DETACH_SESSION Procedure</a>       | Stops debugging the target program                                                             |
| <a href="#">DISABLE_BREAKPOINT Function</a>    | Disables a breakpoint                                                                          |
| <a href="#">ENABLE_BREAKPOINT Function</a>     | Activates an existing breakpoint                                                               |
| <a href="#">EXECUTE Procedure</a>              | Executes SQL or PL/SQL in the target session                                                   |
| <a href="#">GET_INDEXES Function</a>           | Returns the set of indexes for an indexed table                                                |
| <a href="#">GET_MORE_SOURCE Procedure</a>      | Provides additional source in the event of buffer overflow when using <code>SHOW_SOURCE</code> |
| <a href="#">GET_LINE_MAP Function</a>          | Returns information about line numbers in a program unit                                       |
| <a href="#">GET_RUNTIME_INFO Function</a>      | Returns information about the current program                                                  |
| <a href="#">GET_TIMEOUT_BEHAVIOUR Function</a> | Returns the current timeout behavior                                                           |
| <a href="#">GET_VALUE Function</a>             | Gets a value from the currently-running program                                                |
| <a href="#">INITIALIZE Function</a>            | Sets debugID in target session                                                                 |
| <a href="#">PING Procedure</a>                 | Pings the target session to prevent it from timing out                                         |

**Table 58-12 (Cont.) DBMS\_DEBUG Package Subprograms**

| Subprogram                                       | Description                                                                                         |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">PRINT_BACKTRACE Procedure</a>        | Prints a stack backtrace                                                                            |
| <a href="#">PRINT_INSTANTIATIONS Procedure</a>   | Prints a stack backtrace                                                                            |
| <a href="#">PROBE_VERSION Procedure</a>          | Returns the version number of DBMS_DEBUG on the server                                              |
| <a href="#">SELF_CHECK Procedure</a>             | Performs an internal consistency check                                                              |
| <a href="#">SET_BREAKPOINT Function</a>          | Sets a breakpoint in a program unit                                                                 |
| <a href="#">SET_OER_BREAKPOINT Function</a>      | Sets an OER breakpoint                                                                              |
| <a href="#">SET_TIMEOUT Function</a>             | Sets the timeout value                                                                              |
| <a href="#">SET_TIMEOUT_BEHAVIOUR Procedure</a>  | Tells Probe what to do with the target session when a timeout occurs                                |
| <a href="#">SET_VALUE Function</a>               | Sets a value in the currently-running program                                                       |
| <a href="#">SHOW_BREAKPOINTS Procedures</a>      | Returns a listing of the current breakpoints                                                        |
| <a href="#">SHOW_FRAME_SOURCE Procedure</a>      | Fetches the frame source                                                                            |
| <a href="#">SHOW_SOURCE Procedures</a>           | Fetches program source                                                                              |
| <a href="#">SYNCHRONIZE Function</a>             | Waits for program to start running                                                                  |
| <a href="#">TARGET_PROGRAM_RUNNING Procedure</a> | Returns TRUE if the target session is currently executing a stored procedure, or FALSE if it is not |

## 58.7.1 ATTACH\_SESSION Procedure

This procedure notifies the debug session about the target program.

### Syntax

```
DBMS_DEBUG.ATTACH_SESSION (
    debug_session_id IN VARCHAR2,
    diagnostics       IN BINARY_INTEGER := 0);
```

### Parameters

**Table 58-13 ATTACH\_SESSION Procedure Parameters**

| Parameter        | Description                                          |
|------------------|------------------------------------------------------|
| debug_session_id | Debug ID from a call to INITIALIZE in target session |
| diagnostics      | Generate diagnostic output if nonzero                |

## 58.7.2 CONTINUE Function

This function passes the given breakflags (a mask of the events that are of interest) to Probe in the target process. It tells Probe to continue execution of the target process, and it waits until the target process runs to completion or signals an event.

If `info_requested` is not `NULL`, then calls `GET_RUNTIME_INFO`.

### Syntax

```
DBMS_DEBUG.CONTINUE (  
    run_info          IN OUT runtime_info,  
    breakflags        IN      BINARY_INTEGER,  
    info_requested    IN      BINARY_INTEGER := NULL)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-14** CONTINUE Function Parameters

| Parameter                   | Description                                                                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>run_info</code>       | Information about the state of the program                                                                                                                                         |
| <code>breakflags</code>     | Mask of events that are of interest (see the discussion about break flags under <a href="#">DBMS_DEBUG Operational Notes</a> )                                                     |
| <code>info_requested</code> | Which information should be returned in <code>run_info</code> when the program stops (see the discussion of information flags under <a href="#">DBMS_DEBUG Operational Notes</a> ) |

### Return Values

**Table 58-15** CONTINUE Function Return Values

| Return                           | Description                                  |
|----------------------------------|----------------------------------------------|
| <code>success</code>             |                                              |
| <code>error_timeout</code>       | Timed out before the program started running |
| <code>error_communication</code> | Other communication error                    |

## 58.7.3 DEBUG\_OFF Procedure

This procedure notifies the target session that debugging should no longer take place in that session. It is not necessary to call this function before ending the session.

### **WARNING:**

There must be a debug session waiting if `immediate` is `TRUE`.

### Syntax

```
DBMS_DEBUG.DEBUG_OFF;
```

### Usage Notes

The server does not handle this entrypoint specially. Therefore, it attempts to debug this entrypoint.

## 58.7.4 DEBUG\_ON Procedure

This procedure marks the target session so that all PL/SQL is run in debug mode. This must be done before any debugging can take place.

### Syntax

```
DBMS_DEBUG.DEBUG_ON (  
    no_client_side_plsql_engine BOOLEAN := TRUE,  
    immediate                   BOOLEAN := FALSE);
```

### Parameters

**Table 58-16** DEBUG\_ON Procedure Parameters

| Parameter                   | Description                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| no_client_side_plsql_engine | Should be left to its default value unless the debugging session is taking place from a client-side PL/SQL engine                                      |
| immediate                   | If this is TRUE, then the interpreter immediately switches itself into debug-mode, instead of continuing in regular mode for the duration of the call. |

## 58.7.5 DELETE\_BREAKPOINT Function

This function deletes a breakpoint.

### Syntax

```
DBMS_DEBUG.DELETE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-17** DELETE\_BREAKPOINT Function Parameters

| Parameter  | Description                                              |
|------------|----------------------------------------------------------|
| breakpoint | Breakpoint number from a previous call to SET_BREAKPOINT |

### Return Values

**Table 58-18** DELETE\_BREAKPOINT Function Return Values

| Return  | Description |
|---------|-------------|
| success |             |

**Table 58-18 (Cont.) DELETE\_BREAKPOINT Function Return Values**

| Return                    | Description                                                 |
|---------------------------|-------------------------------------------------------------|
| error_no_such_break<br>pt | No such breakpoint exists                                   |
| error_idle_breakpt        | Cannot delete an unused breakpoint                          |
| error_stale_breakpt       | The program unit was redefined since the breakpoint was set |

## 58.7.6 DELETE\_OER\_BREAKPOINT Function

This function deletes an OER breakpoint.

### Syntax

```
DBMS_DEBUG.DELETE_OER_BREAKPOINT (  
    oer IN PLS_INTEGER)  
RETURN PLS_INTEGER;
```

### Parameters

**Table 58-19 DELETE\_OER\_BREAKPOINT Function Parameters**

| Parameter | Description                                |
|-----------|--------------------------------------------|
| oer       | The OER (positive 4-byte number) to delete |

## 58.7.7 DETACH\_SESSION Procedure

This procedure stops debugging the target program.

This procedure may be called at any time, but it does not notify the target session that the debug session is detaching itself, and it does not terminate execution of the target session. Therefore, care should be taken to ensure that the target session does not hang itself.

### Syntax

```
DBMS_DEBUG.DETACH_SESSION;
```

## 58.7.8 DISABLE\_BREAKPOINT Function

This function makes an existing breakpoint inactive but leaves it in place.

### Syntax

```
DBMS_DEBUG.DISABLE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

## Parameters

**Table 58-20** DISABLE\_BREAKPOINT Function Parameters

| Parameter  | Description                                              |
|------------|----------------------------------------------------------|
| breakpoint | Breakpoint number from a previous call to SET_BREAKPOINT |

## Return Values

**Table 58-21** DISABLE\_BREAKPOINT Function Return Values

| Returns               | Description                         |
|-----------------------|-------------------------------------|
| success               |                                     |
| error_no_such_breakpt | No such breakpoint exists           |
| error_idle_breakpt    | Cannot disable an unused breakpoint |

## 58.7.9 ENABLE\_BREAKPOINT Function

This function is the reverse of disabling. This enables a previously disabled breakpoint.

### Syntax

```
DBMS_DEBUG.ENABLE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

## Parameters

**Table 58-22** ENABLE\_BREAKPOINT Function Parameters

| Parameter  | Description                                              |
|------------|----------------------------------------------------------|
| breakpoint | Breakpoint number from a previous call to SET_BREAKPOINT |

## Return Values

**Table 58-23** ENABLE\_BREAKPOINT Function Return Values

| Return                | Description                        |
|-----------------------|------------------------------------|
| success               | Success                            |
| error_no_such_breakpt | No such breakpoint exists          |
| error_idle_breakpt    | Cannot enable an unused breakpoint |

# 58.7.10 EXECUTE Procedure

This procedure executes SQL or PL/SQL code in the target session. The target session is assumed to be waiting at a breakpoint (or other event). The call to `DBMS_DEBUG.EXECUTE` occurs in the debug session, which then asks the target session to execute the code.

## Syntax

```
DBMS_DEBUG.EXECUTE (
  what          IN VARCHAR2,
  frame#        IN BINARY_INTEGER,
  bind_results  IN BINARY_INTEGER,
  results       IN OUT NOCOPY dbms_debug_vc2coll,
  errm          IN OUT NOCOPY VARCHAR2);
```

## Parameters

**Table 58-24 EXECUTE Procedure Parameters**

| Parameter    | Description                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| what         | SQL or PL/SQL source to execute                                                                                                  |
| frame#       | The context in which to execute the code. Only -1 (global context) is supported at this time.                                    |
| bind_results | Whether the source wants to bind to <code>results</code> in order to return values from the target session:<br>0 = No<br>1 = Yes |
| results      | Collection in which to place results, if <code>bind_results</code> is not 0                                                      |
| errm         | Error message, if an error occurred; otherwise, NULL                                                                             |

## Examples

### Example 1

This example executes a SQL statement. It returns no results.

```
DECLARE
  coll sys.dbms_debug_vc2coll; -- results (unused)
  errm VARCHAR2(100);
BEGIN
  dbms_debug.execute('insert into emp(ename,empno,deptno) ' ||
    'values(''LJE'', 1, 1)',
    -1, 0, coll, errm);
END;
```

### Example 2

This example executes a PL/SQL block, and it returns no results. The block is an autonomous transaction, which means that the value inserted into the table becomes visible in the debug session.

```
DECLARE
  coll sys.dbms_debug_vc2coll;
  errm VARCHAR2(100);
BEGIN
  dbms_debug.execute(
```

```

        'DECLARE PRAGMA autonomous_transaction; ' ||
        'BEGIN ' ||
        '    insert into emp(ename, empno, deptno) ' ||
        '    values(''LJE'', 1, 1); ' ||
        ' COMMIT; ' ||
        'END;',
        -1, 0, coll, errm);
END;

```

### Example 3

This example executes a PL/SQL block, and it returns some results.

```

DECLARE
    coll sys.dbms_debug_vc2coll;
    errm VARCHAR2(100);
BEGIN
    dbms_debug.execute(
        'DECLARE ' ||
        '    pp SYS.dbms_debug_vc2coll := SYS.dbms_debug_vc2coll(); ' ||
        '    x PLS_INTEGER; ' ||
        '    i PLS_INTEGER := 1; ' ||
        'BEGIN ' ||
        '    SELECT COUNT(*) INTO x FROM emp; ' ||
        '    pp.EXTEND(x * 6); ' ||
        '    FOR c IN (SELECT * FROM emp) LOOP ' ||
        '        pp(i) := 'Ename: ' || c.ename; i := i+1; ' ||
        '        pp(i) := 'Empno: ' || c.empno; i := i+1; ' ||
        '        pp(i) := 'Job: ' || c.job; i := i+1; ' ||
        '        pp(i) := 'Mgr: ' || c.mgr; i := i+1; ' ||
        '        pp(i) := 'Sal: ' || c.sal; i := i+1; ' ||
        '        pp(i) := null; i := i+1; ' ||
        '    END LOOP; ' ||
        '    :1 := pp; ' ||
        'END;',
        -1, 1, coll, errm);
    each := coll.FIRST;
    WHILE (each IS NOT NULL) LOOP
        dosomething(coll(each));
        each := coll.NEXT(each);
    END LOOP;
END;

```

## 58.7.11 GET\_INDEXES Function

Given a name of a variable or parameter, this function returns the set of its indexes, if it is an indexed table. An error is returned if it is not an indexed table.

### Syntax

```

DBMS_DEBUG.GET_INDEXES (
    varname    IN  VARCHAR2,
    frame#     IN  BINARY_INTEGER,
    handle     IN  program_info,
    entries    OUT index_table)
RETURN BINARY_INTEGER;

```

## Parameters

**Table 58-25 GET\_INDEXES Function Parameters**

| Parameter | Description                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| varname   | Name of the variable to get index information about                                                                                                |
| frame#    | Number of frame in which the variable or parameter resides; NULL for a package variable                                                            |
| handle    | Package description, if object is a package variable                                                                                               |
| entries   | 1-based table of the indexes: if non-NULL, then entries(1) contains the first index of the table, entries(2) contains the second index, and so on. |

## Return Values

**Table 58-26 GET\_INDEXES Function Return Values**

| Return               | Description                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| error_no_such_object | One of the following: <ul style="list-style-type: none"> <li>- The package does not exist</li> <li>- The package is not instantiated</li> <li>- The user does not have privileges to debug the package</li> <li>- The object does not exist in the package</li> </ul> |

## 58.7.12 GET\_MORE\_SOURCE Procedure

When the source does not fit in the buffer provided by the SHOW\_SOURCE Procedure version which produced a formatted buffer, this procedure provides additional source.

### Syntax

```
DBMS_DEBUG.GET_MORE_SOURCE (
    buffer      IN OUT VARCHAR2,
    buflen     IN BINARY_INTEGER,
    piece#     IN BINARY_INTEGER);
```

## Parameters

**Table 58-27 GET\_MORE\_SOURCE Procedure Parameters**

| Parameter | Description                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| buffer    | The buffer                                                                                                                                           |
| buflen    | The length of the buffer                                                                                                                             |
| piece#    | A value between 2 and the value returned in the parameter pieces from the call to the relevant version of the <a href="#">SHOW_SOURCE Procedures</a> |

## Usage Notes

This procedure should be called only after the version of SHOW\_SOURCE that returns a formatted buffer.

Related Topics

- [SHOW\\_SOURCE Procedures](#)  
The procedure gets the source code. There are two overloaded `SHOW_SOURCE` procedures.

58.7.13 GET\_LINE\_MAP Function

This function finds line and entrypoint information about a program so that a debugger can determine the source lines at which it is possible to place breakpoints.

Syntax

```
DBMS_DEBUG.GET_LINE_MAP (  
    program          IN    program_info,  
    maxline          OUT   BINARY_INTEGER,  
    number_of_entry_points OUT BINARY_INTEGER,  
    linemap          OUT   RAW)  
RETURN BINARY_INTEGER;
```

Parameters

Table 58-28 GET\_LINE\_MAP Function Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| program                | A top-level program unit (procedure / package / function / package body, and so on). Its <code>Namespace</code> , <code>Name</code> , and <code>Owner</code> fields must be initialized, the remaining fields are ignored.                                                                                                                                                                                                                                 |
| maxline                | The largest source code line number in 'program'                                                                                                                                                                                                                                                                                                                                                                                                           |
| number_of_entry_points | The number of subprograms in 'program'                                                                                                                                                                                                                                                                                                                                                                                                                     |
| linemap                | A bitmap representing the executable lines of 'program'. If line number <code>N</code> is executable, bit number <code>N MOD 8</code> will be set to 1 at <code>linemap</code> position <code>N / 8</code> . The length of returned <code>linemap</code> is either <code>maxline</code> divided by 8 (plus one if <code>maxline MOD 8</code> is not zero) or 32767 in the unlikely case of <code>maxline</code> being larger than <code>32767 * 8</code> . |

Return Values

Table 58-29 GET\_LINE\_MAP Function Return Values

| Return              | Description                                    |
|---------------------|------------------------------------------------|
| success             | A successful completion                        |
| error_no_debug_info | The program unit exists, but has no debug info |
| error_bad_handle    | No such program unit exists                    |

## 58.7.14 GET\_RUNTIME\_INFO Function

This function returns information about the current program. It is only needed if the `info_requested` parameter to `SYNCHRONIZE` or `CONTINUE` was set to 0.

### Note:

This is currently only used by client-side PL/SQL.

### Syntax

```
DBMS_DEBUG.GET_RUNTIME_INFO (  
    info_requested IN BINARY_INTEGER,  
    run_info      OUT runtime_info)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-30 GET\_RUNTIME\_INFO Function Parameters**

| Parameter                   | Description                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>info_requested</code> | Which information should be returned in <code>run_info</code> when the program stops (see <a href="#">DBMS_DEBUG Operational Notes</a> for information about information flags) |
| <code>run_info</code>       | Information about the state of the program                                                                                                                                      |

## 58.7.15 GET\_TIMEOUT\_BEHAVIOUR Function

This procedure returns the current timeout behavior. This call is made in the target session.

### Syntax

```
DBMS_DEBUG.GET_TIMEOUT_BEHAVIOUR  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-31 GET\_TIMEOUT\_BEHAVIOUR Function Parameters**

| Parameter        | Description                        |
|------------------|------------------------------------|
| <code>oer</code> | The OER (a 4-byte positive number) |

### Return Values

**Table 58-32 GET\_TIMEOUT\_BEHAVIOUR Function Return Values**

| Return               | Description             |
|----------------------|-------------------------|
| <code>success</code> | A successful completion |

Information Flags

```
info_getOerInfo CONSTANT PLS_INTEGER:= 32;
```

Usage Notes

Less functionality is supported on OER breakpoints than on code breakpoints. In particular, note that:

- No "breakpoint number" is returned - the number of the OER is used instead. Thus it is impossible to set duplicate breakpoints on a given OER (it is a no-op).
- It is not possible to disable an OER breakpoint (although clients are free to simulate this by deleting it).
- OER breakpoints are deleted using `delete_oer_breakpoint`.

58.7.16 GET\_VALUE Function

This function gets a value from the currently-running program. There are two overloaded GET\_VALUE functions.

Syntax

```
DBMS_DEBUG.GET_VALUE (  
    variable_name IN VARCHAR2,  
    frame#        IN BINARY_INTEGER,  
    scalar_value  OUT VARCHAR2,  
    format        IN VARCHAR2 := NULL)  
RETURN BINARY_INTEGER;
```

Parameters

Table 58-33 GET\_VALUE Function Parameters

| Parameter     | Description                                            |
|---------------|--------------------------------------------------------|
| variable_name | Name of the variable or parameter                      |
| frame#        | Frame in which it lives; 0 means the current procedure |
| scalar_value  | Value                                                  |
| format        | Optional date format to use, if meaningful             |

Return Values

Table 58-34 GET\_VALUE Function Return Values

| Return               | Description                                                |
|----------------------|------------------------------------------------------------|
| success              | A successful completion                                    |
| error_bogus_frame    | Frame does not exist                                       |
| error_no_debug_info  | Entrypoint has no debug information                        |
| error_no_such_object | variable_name does not exist in frame#                     |
| error_unknown_type   | The type information in the debug information is illegible |
| error_nullvalue      | Value is NULL                                              |

**Table 58-34 (Cont.) GET\_VALUE Function Return Values**

| Return              | Description                                      |
|---------------------|--------------------------------------------------|
| error_indexed_table | The object is a table, but no index was provided |

This form of `GET_VALUE` is for fetching package variables. Instead of a `frame#`, it takes a handle, which describes the package containing the variable.

### Syntax

```
DBMS_DEBUG.GET_VALUE (  
    variable_name IN VARCHAR2,  
    handle        IN program_info,  
    scalar_value  OUT VARCHAR2,  
    format        IN VARCHAR2 := NULL)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-35 GET\_VALUE Function Parameters**

| Parameter     | Description                                        |
|---------------|----------------------------------------------------|
| variable_name | Name of the variable or parameter                  |
| handle        | Description of the package containing the variable |
| scalar_value  | Value                                              |
| format        | Optional date format to use, if meaningful         |

### Return Values

**Table 58-36 GET\_VALUE Function Return Values**

| Return               | Description                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| error_no_such_object | One of the following: <ul style="list-style-type: none"><li>- Package does not exist</li><li>- Package is not instantiated</li><li>- User does not have privileges to debug the package</li><li>- Object does not exist in the package</li></ul> |
| error_indexed_table  | The object is a table, but no index was provided                                                                                                                                                                                                 |

### Examples

This example illustrates how to get the value with a given package `PACK` in schema `SCOTT`, containing variable `VAR`:

```
DECLARE  
    handle      dbms_debug.program_info;  
    resultbuf   VARCHAR2(500);  
    retval      BINARY_INTEGER;  
BEGIN  
    handle.Owner      := 'SCOTT';  
    handle.Name       := 'PACK';
```

```
    handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;  
    retval           := dbms_debug.get_value('VAR', handle, resultbuf, NULL);  
END;
```

## 58.7.17 INITIALIZE Function

This function initializes the target session for debugging.

### Syntax

```
DBMS_DEBUG.INITIALIZE (  
    debug_session_id IN VARCHAR2      := NULL,  
    diagnostics      IN BINARY_INTEGER := 0)  
RETURN VARCHAR2;
```

### Parameters

**Table 58-37 INITIALIZE Function Parameters**

| Parameter        | Description                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------|
| debug_session_id | Name of session ID. If NULL, then a unique ID is generated.                                                            |
| diagnostics      | Indicates whether to dump diagnostic output to the tracefile:<br>0 = (default) no diagnostics<br>1 = print diagnostics |

### Return Values

The newly-registered debug session ID (debugID)

### Usage Notes

You cannot use `DBMS_DEBUG` and the JDWP-based debugging interface simultaneously. This call will either fail with an ORA-30677 error if the session is currently being debugged with the JDWP-based debugging interface or, if the call succeeds, any further use of the JDWP-based interface to debug this session will be disallowed.

Calls to `DBMS_DEBUG` will succeed only if either the caller or the specified debug role carries the `DEBUG CONNECT SESSION` privilege. Failing that, an ORA-1031 error will be raised. Other exceptions are also possible if a debug role is specified but the password does not match, or if the calling user has not been granted the role, or the role is application-enabled and this call does not originate from within the role-enabling package.

The `CREATE ANY PROCEDURE` privilege does not affect the visibility of routines through the debugger. A privilege `DEBUG` for each object has been introduced with a corresponding `DEBUG ANY PROCEDURE` variant. These are required in order to see routines owned by users other than the session's login user.

Authentication of the debug role and the check for `DEBUG CONNECT SESSION` privilege will be done in the context of the caller to this routine. If the caller is a definer's rights routine or has been called from one, only privileges granted to the defining user, the debug role, or `PUBLIC` will be used to check for `DEBUG CONNECT SESSION`. If this call is from within a definer's rights routine, the debug role, if specified, must be one that has been granted to that definer, but it need not also have been granted to the session login user or be enabled in the calling session at the time the call is made.

The checks made by the debugger after this call is made looking for the `DEBUG` privilege on individual procedures will be done in the context of the session's login user, the roles that were enabled at session level at the moment this call was made (even if those roles were not available within a definer's rights environment of the call), and the debug role.

## 58.7.18 PING Procedure

This procedure pings the target session to prevent it from timing out. Use this procedure when execution is suspended in the target session, for example at a breakpoint.

If the `timeout_behaviour` is set to `retry_on_timeout` then this procedure is not necessary.

### Syntax

```
DBMS_DEBUG.PING;
```

### Exceptions

Oracle will display the `no_target_program` exception if there is no target program or if the target session is not currently waiting for input from the debug session.

### Usage Notes

Timeout options for the target session are registered with the target session by calling `set_timeout_behaviour`:

- `retry_on_timeout` - Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.
- `continue_on_timeout` - Continue execution, using same event flags.
- `nodebug_on_timeout` - Turn debug-mode OFF (in other words, call `debug_off`) and then continue execution. No more events will be generated by this target session unless it is re-initialized by calling `debug_on`.
- `abort_on_timeout` - Continue execution, using the `abort_execution` flag, which should cause the program to terminate immediately. The session remains in debug-mode.

```
retry_on_timeout CONSTANT BINARY_INTEGER:= 0;  
continue_on_timeout CONSTANT BINARY_INTEGER:= 1;  
nodebug_on_timeout CONSTANT BINARY_INTEGER:= 2;  
abort_on_timeout CONSTANT BINARY_INTEGER:= 3;
```

## 58.7.19 PRINT\_BACKTRACE Procedure

This procedure prints a backtrace listing of the current execution stack. This should only be called if a program is currently running.

There are two overloaded `PRINT_BACKTRACE` procedures.

### Syntax

```
DBMS_DEBUG.PRINT_BACKTRACE (  
    listing IN OUT VARCHAR2);  
  
DBMS_DEBUG.PRINT_BACKTRACE (  
    backtrace OUT backtrace_table);
```

## Parameters

**Table 58-38 PRINT\_BACKTRACE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| listing   | A formatted character buffer with embedded newlines                                                                                                                                                                                          |
| backtrace | 1-based indexed table of backtrace entries. The currently-running procedure is the last entry in the table (that is, the frame numbering is the same as that used by <code>GET_VALUE</code> ). Entry 1 is the oldest procedure on the stack. |

## 58.7.20 PRINT\_INSTANTIATIONS Procedure

This procedure returns a list of the packages that have been instantiated in the current session.

### Syntax

```
DBMS_DEBUG.PRINT_INSTANTIATIONS (  
    pkgs    IN OUT NOCOPY backtrace_table,  
    flags   IN BINARY_INTEGER);
```

## Parameters

**Table 58-39 PRINT\_INSTANTIATIONS Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pkgs      | The instantiated packages                                                                                                                                                                                                                                                                                                                |
| flags     | Bitmask of options: <ul style="list-style-type: none"><li>• 1 - show specs</li><li>• 2 - show bodies</li><li>• 4 - show local instantiations</li><li>• 8 - show remote instantiations (NYI)</li><li>• 16 - do a fast job. The routine does not test whether debug information exists or whether the libunit is shrink-wrapped.</li></ul> |

### Exceptions

`no_target_program` - target session is not currently executing

### Usage Notes

On return, `pkgs` contains a `program_info` for each instantiation. The valid fields are: Namespace, Name, Owner, and LibunitType.

In addition, `Line#` contains a bitmask of:

- 1 - the libunit contains debug info
- 2 - the libunit is shrink-wrapped

## 58.7.21 PROBE\_VERSION Procedure

This procedure returns the version number of DBMS\_DEBUG on the server.

### Syntax

```
DBMS_DEBUG.PROBE_VERSION (  
    major out BINARY_INTEGER,  
    minor out BINARY_INTEGER);
```

### Parameters

**Table 58-40 PROBE\_VERSION Procedure Parameters**

| Parameter | Description                                                |
|-----------|------------------------------------------------------------|
| major     | Major version number                                       |
| minor     | Minor version number: increments as functionality is added |

## 58.7.22 SELF\_CHECK Procedure

This procedure performs an internal consistency check. SELF\_CHECK also runs a communications test to ensure that the Probe processes are able to communicate.

If SELF\_CHECK does not return successfully, then an incorrect version of DBMS\_DEBUG was probably installed on this server. The solution is to install the correct version (pblog.sql loads DBMS\_DEBUG and the other relevant packages).

### Syntax

```
DBMS_DEBUG.SELF_CHECK (  
    timeout IN binary_integer := 60);
```

### Parameters

**Table 58-41 SELF\_CHECK Procedure Parameters**

| Parameter | Description                                                           |
|-----------|-----------------------------------------------------------------------|
| timeout   | The timeout to use for the communication test. Default is 60 seconds. |

### Exceptions

**Table 58-42 SELF\_CHECK Procedure Exceptions**

| Exception              | Description                       |
|------------------------|-----------------------------------|
| OER-6516               | Probe version is inconsistent     |
| pipe_creation_failure  | Could not create a pipe           |
| pipe_send_failure      | Could not write data to the pipe  |
| pipe_receive_failure   | Could not read data from the pipe |
| pipe_datatype_mismatch | Datatype in the pipe was wrong    |

**Table 58-42 (Cont.) SELF\_CHECK Procedure Exceptions**

| Exception       | Description                  |
|-----------------|------------------------------|
| pipe_data_error | Data got garbled in the pipe |

All of these exceptions are fatal. They indicate a serious problem with Probe that prevents it from working correctly.

## 58.7.23 SET\_BREAKPOINT Function

This function sets a breakpoint in a program unit, which persists for the current session.

Execution pauses if the target program reaches the breakpoint.

### Syntax

```
DBMS_DEBUG.SET_BREAKPOINT (  
    program      IN  program_info,  
    line#        IN  BINARY_INTEGER,  
    breakpoint#  OUT BINARY_INTEGER,  
    fuzzy        IN  BINARY_INTEGER := 0,  
    iterations   IN  BINARY_INTEGER := 0)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-43 SET\_BREAKPOINT Function Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| program     | Information about the program unit in which the breakpoint is to be set. (In version 2.1 and later, the namespace, name, owner, and dblink may be set to NULL, in which case the breakpoint is placed in the currently-running program unit.)                                             |
| line#       | Line at which the breakpoint is to be set                                                                                                                                                                                                                                                 |
| breakpoint# | On successful completion, contains the unique breakpoint number by which to refer to the breakpoint                                                                                                                                                                                       |
| fuzzy       | Only applicable if there is no executable code at the specified line:<br>0 means return <code>error_illegal_line</code><br>1 means search forward for an adjacent line at which to place the breakpoint<br>-1 means search backward for an adjacent line at which to place the breakpoint |
| iterations  | Number of times to wait before signalling this breakpoint                                                                                                                                                                                                                                 |

### Return Values

**Note:**

The `fuzzy` and `iterations` parameters are not yet implemented

**Table 58-44 SET\_BREAKPOINT Function Return Values**

| Return             | Description                          |
|--------------------|--------------------------------------|
| success            | A successful completion              |
| error_illegal_line | Cannot set a breakpoint at that line |
| error_bad_handle   | No such program unit exists          |

## 58.7.24 SET\_OER\_BREAKPOINT Function

This function sets an OER breakpoint.

### Syntax

```
DBMS_DEBUG.SET_OER_BREAKPOINT (  
    oer IN PLS_INTEGER)  
RETURN PLS_INTEGER;
```

### Parameters

**Table 58-45 SET\_OER\_BREAKPOINT Function Parameters**

| Parameter | Description                             |
|-----------|-----------------------------------------|
| oer       | The OER (positive 4-byte number) to set |

### Return Values

**Table 58-46 SET\_OER\_BREAKPOINT Function Return Values**

| Return                | Description                   |
|-----------------------|-------------------------------|
| success               | A successful completion       |
| error_no_such_breakpt | No such OER breakpoint exists |

## 58.7.25 SET\_TIMEOUT Function

This function sets the timeout value and returns the new timeout value.

### Syntax

```
DBMS_DEBUG.SET_TIMEOUT (  
    timeout BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 58-47 SET\_TIMEOUT Function Parameters**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| timeout   | The timeout to use for communication between the target and debug sessions |

## 58.7.26 SET\_TIMEOUT\_BEHAVIOUR Procedure

This procedure tells Probe what to do with the target session when a timeout occurs. This call is made in the target session.

### Syntax

```
DBMS_DEBUG.SET_TIMEOUT_BEHAVIOUR (  
    behaviour IN PLS_INTEGER);
```

### Parameters

**Table 58-48 SET\_TIMEOUT\_BEHAVIOUR Procedure Parameters**

| Parameter                         | Description                                                                                                                                                                                                       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| behaviour - One of the following: |                                                                                                                                                                                                                   |
| retry_on_timeout                  | Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.                                                                                                                      |
| continue_on_timeout               | Continue execution, using same event flags                                                                                                                                                                        |
| nodebug_on_timeout                | Turn debug-mode OFF (in other words, call <code>debug_off</code> ) and continue execution. No more events will be generated by this target session unless it is re-initialized by calling <code>debug_on</code> . |
| abort_on_timeout                  | Continue execution, using the <code>abort_execution</code> flag, which should cause the program to terminate immediately. The session remains in debug-mode.                                                      |

### Exceptions

unimplemented - the requested behavior is not recognized

### Usage Notes

The default behavior (if this procedure is not called) is `continue_on_timeout`, since it allows a debugger client to reestablish control (at the next event) but does not cause the target session to hang indefinitely.

## 58.7.27 SET\_VALUE Function

This function sets a value in the currently-running program. There are two overloaded `SET_VALUE` functions.

### Syntax

```
DBMS_DEBUG.SET_VALUE (  
    frame#                IN binary_integer,  
    assignment_statement IN varchar2)  
RETURN BINARY_INTEGER;
```

```
DBMS_DEBUG.SET_VALUE (  
    handle                IN program_info,  
    assignment_statement IN VARCHAR2)  
RETURN BINARY_INTEGER;
```

## Parameters

**Table 58-49 SET\_VALUE Function Parameters**

| Parameter            | Description                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| frame#               | Frame in which the value is to be set; 0 means the currently executing frame.                                                                                                                                                    |
| handle               | Description of the package containing the variable                                                                                                                                                                               |
| assignment_statement | An assignment statement (which must be legal PL/SQL) to run in order to set the value. For example, 'x := 3;'.<br>Only scalar values are supported in this release. The right side of the assignment statement must be a scalar. |

## Return Values

**Table 58-50 SET\_VALUE Function Return Values**

| Return                | Description                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| success               | -                                                                                                                                                                                                                                                |
| error_illegal_value   | Not possible to set it to that value                                                                                                                                                                                                             |
| error_illegal_null    | Cannot set to NULL because object type specifies it as 'not NULL'                                                                                                                                                                                |
| error_value_malformed | Value is not a scalar                                                                                                                                                                                                                            |
| error_name_incomplete | The assignment statement does not resolve to a scalar. For example, 'x := 3;', if x is a record.                                                                                                                                                 |
| error_no_such_object  | One of the following: <ul style="list-style-type: none"><li>- Package does not exist</li><li>- Package is not instantiated</li><li>- User does not have privileges to debug the package</li><li>- Object does not exist in the package</li></ul> |

## Usage Notes

In some cases, the PL/SQL compiler uses temporaries to access package variables, and does not guarantee to update such temporaries. It is possible, although unlikely, that modification to a package variable using SET\_VALUE might not take effect for a line or two.

## Examples

To set the value of SCOTT.PACK.var to 6:

```
DECLARE
    handle  dbms_debug.program_info;
    retval  BINARY_INTEGER;
BEGIN
    handle.Owner      := 'SCOTT';
    handle.Name       := 'PACK';
    handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;
    retval           := dbms_debug.set_value(handle, 'var := 6;');
END;
```

## 58.7.28 SHOW\_BREAKPOINTS Procedures

There are two overloaded procedures that return a listing of the current breakpoints. There are three overloaded `SHOW_BREAKPOINTS` procedures.

### Syntax

```
DBMS_DEBUG.SHOW_BREAKPOINTS (  
    listing    IN OUT VARCHAR2);  
  
DBMS_DEBUG.SHOW_BREAKPOINTS (  
    listing    OUT breakpoint_table);  
  
DBMS_DEBUG.SHOW_BREAKPOINTS (  
    code_breakpoints OUT breakpoint_table,  
    oer_breakpoints  OUT oer_table);
```

### Parameters

**Table 58-51** SHOW\_BREAKPOINTS Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| listing          | A formatted buffer (including newlines) of the breakpoints.<br>Indexed table of breakpoint entries. The breakpoint number is indicated by the index into the table. Breakpoint numbers start at 1 and are reused when deleted. |
| code_breakpoints | The indexed table of breakpoint entries, indexed by breakpoint number                                                                                                                                                          |
| oer_breakpoints  | The indexed table of OER breakpoints, indexed by OER                                                                                                                                                                           |

## 58.7.29 SHOW\_FRAME\_SOURCE Procedure

The procedure gets the source code. There are two overloaded `SHOW_SOURCE` procedures.

### Syntax

```
DBMS_DEBUG.SHOW_FRAME_SOURCE (  
    first_line IN      BINARY_INTEGER,  
    last_line  IN      BINARY_INTEGER,  
    source     IN OUT NOCOPY vc2_table,  
    frame_num  IN      BINARY_INTEGER);
```

### Parameters

**Table 58-52** SHOW\_FRAME\_SOURCE Procedure Parameters

| Parameter  | Description                                                                                   |
|------------|-----------------------------------------------------------------------------------------------|
| first_line | Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes) |
| last_line  | Line number of last line to fetch. No lines are fetched past the end of the program.          |
| source     | The resulting table, which may be indexed by line#                                            |
| frame_num  | 1-based frame number                                                                          |

Usage Notes

- You use this function only when backtrace shows an anonymous unit is executing at a given frame position and you need to view the source in order to set a breakpoint.
- If frame number is top of the stack and it's an anonymous block then SHOW\_SOURCE can also be used.
- If it's a stored PL/SQL package/function/procedure then use SQL as described in the Usage Notes to SHOW\_SOURCE Procedures.

58.7.30 SHOW\_SOURCE Procedures

The procedure gets the source code. There are two overloaded SHOW\_SOURCE procedures.

Syntax

```
DBMS_DEBUG.SHOW_SOURCE (
    first_line IN BINARY_INTEGER,
    last_line  IN BINARY_INTEGER,
    source     OUT vc2_table);

DBMS_DEBUG.SHOW_SOURCE (
    first_line IN BINARY_INTEGER,
    last_line  IN BINARY_INTEGER,
    window     IN BINARY_INTEGER,
    print_arrow IN BINARY_INTEGER,
    buffer     IN OUT VARCHAR2,
    buflen     IN BINARY_INTEGER,
    pieces     OUT BINARY_INTEGER);
```

Parameters

Table 58-53 SHOW\_SOURCE Procedure Parameters

| Parameter   | Description                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------|
| first_line  | Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes) |
| last_line   | Line number of last line to fetch. No lines are fetched past the end of the program.          |
| source      | The resulting table, which may be indexed by line#                                            |
| window      | 'Window' of lines (the number of lines around the current source line)                        |
| print_arrow | Nonzero means to print an arrow before the current line                                       |
| buffer      | Buffer in which to place the source listing                                                   |
| buflen      | Length of buffer                                                                              |
| pieces      | Set to nonzero if not all the source could be placed into the given buffer                    |

Return Values

An indexed table of source-lines. The source lines are stored starting at first\_line. If any error occurs, then the table is empty.

Usage Notes

The best way to get the source code (for a program that is being run) is to use SQL. For example:

```
DECLARE
    info DBMS_DEBUG.runtime_info;
BEGIN
    -- call DBMS_DEBUG.SYNCHRONIZE, CONTINUE,
    -- or GET_RUNTIME_INFO to fill in 'info'
    SELECT text INTO <buffer> FROM all_source
    WHERE owner = info.Program.Owner
        AND name = info.Program.Name
        AND line = info.Line#;
END;
```

However, this does not work for nonpersistent programs (for example, anonymous blocks and trigger invocation blocks). For nonpersistent programs, call `SHOW_SOURCE`. There are two flavors: one returns an indexed table of source lines, and the other returns a packed (and formatted) buffer.

The second overloading of `SHOW_SOURCE` returns the source in a formatted buffer, complete with line-numbers. It is faster than the indexed table version, but it does not guarantee to fetch all the source.

If the source does not fit in bufferlength (`buflen`), then additional pieces can be retrieved using the `GET_MORE_SOURCE` procedure (`pieces` returns the number of additional pieces that need to be retrieved).

58.7.31 SYNCHRONIZE Function

This function waits until the target program signals an event. If `info_requested` is not `NULL`, then it calls `GET_RUNTIME_INFO`.

Syntax

```
DBMS_DEBUG.SYNCHRONIZE (
    run_info          OUT runtime_info,
    info_requested IN  BINARY_INTEGER := NULL)
RETURN BINARY_INTEGER;
```

Parameters

Table 58-54 SYNCHRONIZE Function Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| run_info       | Structure in which to write information about the program. By default, this includes information about what program is running and at which line execution has paused.                                                                                                         |
| info_requested | Optional bit-field in which to request information other than the default (which is <code>info_getStackDepth + info_getLineInfo</code> ). 0 means that no information is requested at all (see <a href="#">DBMS_DEBUG Operational Notes</a> for more about information flags). |

## Return Values

**Table 58-55** SYNCHRONIZE Function Return Values

| Return              | Description                                    |
|---------------------|------------------------------------------------|
| success             | A successful completion                        |
| error_timeout       | Timed out before the program started execution |
| error_communication | Other communication error                      |

## 58.7.32 TARGET\_PROGRAM\_RUNNING Procedure

This procedure returns `TRUE` if the target session is currently executing a stored procedure, or `FALSE` if it is not.

### Syntax

```
DBMS_DEBUG.TARGET_PROGRAM_RUNNING  
RETURN BOOLEAN;
```

## DBMS\_DEBUG\_JDWP

The `DBMS_DEBUG_JDWP` provides the interface to initiate and control the debugging of PL/SQL stored procedures and Java stored procedures over Java Debug Wire Protocol (JDWP).

This chapter contains the following topics:

- [DBMS\\_DEBUG\\_JDWP Overview](#)
- [DBMS\\_DEBUG\\_JDWP Security Model](#)
- [Summary of DBMS\\_DEBUG\\_JDWP Subprograms](#)

### 59.1 DBMS\_DEBUG\_JDWP Overview

Oracle supports the debugging of PL/SQL stored procedures and Java stored procedures over JDWP. Using the `DBMS_DEBUG_JDWP` package, you can:

- Retrieve the session ID of the current session and serial number
- Connect a database session to a debugger over JDWP
- Set the NLS parameters to change the formats in which PL/SQL program values are represented over JDWP

### 59.2 DBMS\_DEBUG\_JDWP Security Model

The debugging user invoking a `DBMS_DEBUG_JDWP` subprogram requires a privilege to connect the target database session to the debugger.

**Table 59-1 System Privileges**

| System Privilege                   | Description                                                        |
|------------------------------------|--------------------------------------------------------------------|
| <code>DEBUG CONNECT SESSION</code> | Allows a user to connect his current session to a debugger         |
| <code>DEBUG CONNECT ANY</code>     | Allows a user to connect a session by any logon user to a debugger |

In addition, the user can also be granted the following user privilege to debug another user's session.

**Table 59-2 User Privileges**

| User Privilege                                  | Description                                                                                                                  |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>DEBUG CONNECT ON USER &lt;user&gt;</code> | Allows a user to connect any of the specified user's logon sessions to a debugger to debug another user's session or his own |

## 59.3 Summary DBMS\_DEBUG\_JDWP Subprograms

This table lists the DBMS\_DEBUG\_JDWP subprograms and briefly describes them.

**Table 59-3 DBMS\_DEBUG\_JDWP Package Subprograms**

| Subprogram                                       | Description                                                                                                                                                                                                                                  |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CONNECT_TCP Procedure</a>            | Connects the specified session to the debugger waiting at <code>host:port</code>                                                                                                                                                             |
| <a href="#">CURRENT_SESSION_ID Function</a>      | Gets the current session's session ID                                                                                                                                                                                                        |
| <a href="#">CURRENT_SESSION_SERIAL Function</a>  | Gets the current session's session serial number                                                                                                                                                                                             |
| <a href="#">DISCONNECT Procedure</a>             | Disconnects the specified session from any debugger with which it is connected                                                                                                                                                               |
| <a href="#">GET-NLS_PARAMETER Function</a>       | Gets the value of the specified NLS parameter affecting the format in which NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings as they are presented through JDWP |
| <a href="#">PROCESS_CONNECT_STRING Procedure</a> | Connects a session to a debugger without having to directly modify an application's code                                                                                                                                                     |
| <a href="#">SET-NLS_PARAMETER Procedure</a>      | Sets the value of the specified NLS parameter affecting the format in which NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings as they are presented through JDWP |

### 59.3.1 CONNECT\_TCP Procedure

This procedure connects the specified session to the debugger waiting at `host:port`.

#### Syntax

```
DBMS_DEBUG_JDWP.CONNECT_TCP(  
    host          IN  VARCHAR2,  
    port          IN  VARCHAR2,  
    session_id    IN  PLS_INTEGER := NULL,  
    session_serial IN  PLS_INTEGER := NULL,  
    debug_role    IN  VARCHAR2  := NULL,  
    debug_role_pwd IN  VARCHAR2  := NULL,  
    option_flags  IN  PLS_INTEGER := 0,  
    extensions_cmd_set IN PLS_INTEGER := 128);
```

#### Parameters

**Table 59-4 CONNECT\_TCP Parameters**

| Parameter         | Description                                |
|-------------------|--------------------------------------------|
| <code>host</code> | The host name the debugger is waiting at   |
| <code>port</code> | The port number the debugger is waiting at |

**Table 59-4 (Cont.) CONNECT\_TCP Parameters**

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>session_id</code>         | Session ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>session_serial</code>     | Session number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>debug_role</code>         | Debug role                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>debug_role_pwd</code>     | Debug password                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>option_flags</code>       | Values: <ul style="list-style-type: none"> <li>• 1 : Does not suspend the program until the next client/server request begins. This can be used to hide the startup sequence from end users, who may only want to see their own code</li> <li>• 2 : Forces the connection even if the session appears to be connected to a debugger. This should best only be specified after some human-interaction confirmation step has occurred; i.e., if an attempt without this option raised ORA-30677, then if the user confirms, retry with this bit set.</li> </ul> These may be added together to select multiple option choices. |
| <code>extensions_cmd_set</code> | The ID of the Oracle JDWP extension command set                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Exceptions

**Table 59-5 CONNECT\_TCP Exceptions**

| Exception | Description                                                    |
|-----------|----------------------------------------------------------------|
| ORA-00022 | Invalid session ID                                             |
| ORA-01031 | Insufficient privilege                                         |
| ORA-30677 | Session is already connected to a debugger                     |
| ORA-30681 | Improper value for argument<br><code>EXTENSIONS_CMD_SET</code> |
| ORA-30682 | Improper value for argument <code>OPTION_FLAGS</code>          |
| ORA-30683 | Failure establishing connection to debugger                    |

## Usage Notes

- To connect the current session to a debugger, you can pass `NULL` to both the `session_id` and `session_serial` parameters.
- To connect a different session, you need to find out its ID and serial. These are available in the `v$sql_debuggable_sessions` view. The Instance Manager option of Oracle Enterprise Manager is one example of a user interface that displays these values to users. You can also find the values of these for your own session using the [CURRENT\\_SESSION\\_ID Function](#) and [CURRENT\\_SESSION\\_SERIAL Function](#).
- The `debug_role` and `debug_role_pwd` arguments allow the user to name any role as the "debug role", which will be available to privilege checking when checking for permissions to

connect the session and when checking permissions available on objects within the debugged session. Both the role and its password are passed here as strings and not as identifiers, so double quotes should not be used but case matters. If the original role name wasn't double-quoted, it should be specified here in upper case.

- An ORA-30677 indicates that the requested session is already being debugged. It is suggested in this case that the user be asked to confirm that (s)he desires to steal the session from the existing connection, and then either an explicit disconnect call or the use of the `connect_force_connect` option bit can be used to allow the connection to succeed on a second attempt. Note that using the `connect_force_connect` bit will avoid the session being allowed to run freely if it is currently suspended through the debugger - in other words, this bit lets you steal a session from one debugger to another without actually disturbing the state of the session.

## 59.3.2 CURRENT\_SESSION\_ID Function

This function gets the current session's session ID

### Syntax

```
DBMS_DEBUG_JDWP.CURRENT_SESSION_ID
RETURN PLS_INTEGER;
```

## 59.3.3 CURRENT\_SESSION\_SERIAL Function

This function gets the current session's session number.

### Syntax

```
DBMS_DEBUG_JDWP.CURRENT_SESSION_SERIAL
RETURN PLS_INTEGER;
```

## 59.3.4 DISCONNECT Procedure

This procedure disconnects the specified session from any debugger with which it is connected.

### Syntax

```
DBMS_DEBUG_JDWP.DISCONNECT(
    session_id      IN PLS_INTEGER := NULL,
    session_serial  IN PLS_INTEGER := NULL);
```

### Parameters

**Table 59-6 DISCONNECT Procedure Parameters**

| Parameter                   | Description    |
|-----------------------------|----------------|
| <code>session_id</code>     | Session ID     |
| <code>session_serial</code> | Session number |

### Usage Notes

- If the session to disconnect is the current session, the session will be allowed to run freely after disconnecting the debugger. Otherwise, the session will be terminated.

- The same rights are required for this call as for connect, except when disconnecting the current session and the effective user at the time of the call is the same as the login user of the session where no privilege is required.

### 59.3.5 GET\_NLS\_PARAMETER Function

This function gets the value of the specified NLS parameter affecting the format in which the NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings, as they are presented through JDWP.

These values are private to the current session, but further are private to the debugger mechanisms, separate from the values used to convert values within the debugged program itself.

#### Syntax

```
DBMS_DEBUG_JDWP.GET_NLS_PARAMETER(  
    name    IN VARCHAR2)  
RETURN VARCHAR2;
```

#### Parameters

**Table 59-7 GET\_NLS\_PARAMETER Function Parameters**

| Parameter | Description             |
|-----------|-------------------------|
| name      | Specified NLS parameter |

#### Usage Notes

- When any variable value is read or assigned through JDWP, or when either `GET_NLS_PARAMETER` Function or `SET_NLS_PARAMETER` Procedure is first invoked in a session, the debugger mechanisms make a private copy of the then-current NLS\_LANGUAGE, NLS\_TERRITORY, NLS\_CALENDAR, NLS\_DATE\_LANGUAGE, NLS\_NUMERIC\_CHARACTERS, NLS\_TIMESTAMP\_FORMAT, NLS\_TIMESTAMP\_TZ\_FORMAT, NLS\_TIME\_FOMAT and NLS\_TIME\_TZ\_FORMAT values. These private copies may be read using this `GET_NLS_PARAMETER` Functioncall and changed using the following call to the [SET\\_NLS\\_PARAMETER Procedure](#).
- Once the debugger's private copy of the NLS parameters is established, changes made to the NLS parameters in the current session using the `ALTER SESSION` statement will have no effect on the formatting of values as seen through JDWP. To modify the NLS parameters used for JDWP, one must use the `SET_NLS_PARAMETER` Procedure . By the same token, changes made to the debugger's private copy of the NLS parameters using `SET_NLS_PARAMETER` Procedure will have no effect on the debugged program itself.
- Date values are always formatted for JDWP use using the `NLS_TIMESTAMP_FORMAT`. The default format for `DATE` (`NLS_DATE_FORMAT`) used in a session most often does not show the time information that is in fact present in the value, and for debugging purposes it seems beneficial to always display that information.

### 59.3.6 PROCESS\_CONNECT\_STRING Procedure

This procedure connects a session to a debugger in two ways, so that you do not have to directly modify the application code.

The two ways are:

- Using the `ORA_DEBUG_JDWP` environment variable, when running an OCI program
- Setting a web browser cookie called `OWA_DEBUG_<dad>`, when running an application through the PL/SQL Web Gateway

### Syntax

```
DBMS_DEBUG_JDWP.PROCESS_CONNECT_STRING (
    connect_string      IN  VARCHAR2,
    connect_string_type IN  PLS_INTEGER);
```

### Parameters

**Table 59-8 PROCESS\_CONNECT\_STRING Procedure Parameters**

| Parameter                        | Description                                                                                                                                                                                                                                                        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>connect_string</code>      | The <code>ORA_DEBUG_JDWP</code> environment variable or <code>OWA_DEBUG_&lt;dad&gt;</code> cookie value that contains the JDWP connection information such as the host and port number of the debugger to connect to                                               |
| <code>connect_string_type</code> | Can have the following two values: <ul style="list-style-type: none"> <li>• 1 if the connect string value is retrieved from the <code>ORA_DEBUG_JDWP</code> environment</li> <li>• 2 if the value is from the <code>OWA_DEBUG_&lt;dad&gt;</code> cookie</li> </ul> |

### Exceptions

**Table 59-9 PROCESS\_CONNECT\_STRING Procedure Exceptions**

| Exception | Description                                                         |
|-----------|---------------------------------------------------------------------|
| ORA-00022 | Invalid session ID                                                  |
| ORA-01031 | Insufficient privilege                                              |
| ORA-30677 | Session is already connected to a debugger                          |
| ORA-30681 | Improper value for argument <code>EXTENSIONS_CMD_SET</code>         |
| ORA-30682 | Improper value for argument <code>OPTION_FLAGS</code>               |
| ORA-30683 | Failure establishing connection to debugger                         |
| ORA-30689 | Improper value for environment variable <code>ORA_DEBUG_JDWP</code> |

## 59.3.7 SET\_NLS\_PARAMETER Procedure

This function sets the value of the specified NLS parameter affecting the format in which `NUMBER`, `DATE`, `TIME (WITH TIME ZONE)` and `TIMESTAMP (WITH TIME ZONE)` runtime values of PL/SQL programs are converted to strings as they are presented through JDWP.

These values are private to the current session, but further are private to the debugger mechanisms, separate from the values used to convert values within the debugged program itself.

## Syntax

```
DBMS_DEBUG_JDWP.SET_NLS_PARAMETER(  
    name      IN  VARCHAR2,  
    value     IN  VARCHAR2);
```

## Parameters

**Table 59-10 SET\_NLS\_PARAMETER Procedure Parameters**

| Parameter | Description                      |
|-----------|----------------------------------|
| name      | Specified NLS parameter          |
| value     | Value of specified NLS parameter |

## Usage Notes

- When any variable value is read or assigned through JDWP, or when either `GET_NLS_PARAMETER` Function or `SET_NLS_PARAMETER` Procedure is first invoked in a session, the debugger mechanisms make a private copy of the then-current `NLS_LANGUAGE`, `NLS_TERRITORY`, `NLS_CALENDAR`, `NLS_DATE_LANGUAGE`, `NLS_NUMERIC_CHARACTERS`, `NLS_TIMESTAMP_FORMAT`, `NLS_TIMESTAMP_TZ_FORMAT`, `NLS_TIME_FOMAT` and `NLS_TIME_TZ_FORMAT` values. These private copies may be read by calling the [GET\\_NLS\\_PARAMETER Function](#) and changed using the following call to the `SET_NLS_PARAMETER` Procedure.
- Once the debugger's private copy of the NLS parameters is established, changes made to the NLS parameters in the current session using the `ALTER SESSION` statement will have no effect on the formatting of values as seen through JDWP. To modify the NLS parameters used for JDWP, one must use the `SET_NLS_PARAMETER` Procedure. By the same token, changes made to the debugger's private copy of the NLS parameters using `SET_NLS_PARAMETER` Procedure will have no effect on the debugged program itself.
- Date values are always formatted for JDWP use using the `NLS_TIMESTAMP_FORMAT`. The default format for `DATE` (`NLS_DATE_FORMAT`) used in a session most often does not show the time information that is in fact present in the value, and for debugging purposes it seems beneficial to always display that information.

# DBMS\_DEBUG\_JDWP\_CUSTOM

The `DBMS_DEBUG_JDWP_CUSTOM` package provides database users a means to perform custom handling of a debug connection request of a database session to a debugger using the Java Debug Wire Protocol (JDWP).

This chapter contains the following topics:

- [DBMS\\_DEBUG\\_JDWP\\_CUSTOM Overview](#)
- [DBMS\\_DEBUG\\_JDWP\\_CUSTOM Security Model](#)
- [Summary of DBMS\\_DEBUG\\_JDWP\\_CUSTOM Subprograms](#)

## 60.1 DBMS\_DEBUG\_JDWP\_CUSTOM Overview

`DBMS_DEBUG_JDWP_CUSTOM` package is invoked when you attempt to connect your database session to a debugger, using the Java Debug Wire Protocol (JDWP). Before connecting to the database, you must set the `ORA_DEBUG_JDWP` environment variable in your client-side OCI application. Defining this package in your schema enables you to perform custom actions before connecting your database session to the debugger.

## 60.2 DBMS\_DEBUG\_JDWP\_CUSTOM Security Model

This default implementation of the `DBMS_DEBUG_JDWP_CUSTOM` package does not perform any additional security checks and only invokes the `DBMS_DEBUG_JDWP` package for making the debug connection. When the `DBMS_DEBUG_JDWP` package is invoked, it checks for the necessary `DEBUG CONNECT` system or user privilege before making the connection.

A database user who wants to perform additional custom security checks, must perform the following steps to override this default implementation:

- Define the `DBMS_DEBUG_JDWP_CUSTOM` package in the user's own schema.
- Implement the check before invoking the `DBMS_DEBUG_JDWP` package in the user's local copy of the package.

## 60.3 Summary DBMS\_DEBUG\_JDWP\_CUSTOM Subprograms

This table summarizes the `DBMS_DEBUG_JDWP_CUSTOM` subprograms.

**Table 60-1 DBMS\_DEBUG\_JDWP\_CUSTOM Subprograms**

| Subprogram                                 | Description                                                                                                       |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">CONNECT_DEBUGGER Procedure</a> | This procedure is invoked to handle the debug connection request of the current database session to the debugger. |

## 60.3.1 CONNECT\_DEBUGGER Procedure

This procedure is invoked to handle the debug connection request of the current database session to the debugger.

### Syntax

```
PROCEDURE CONNECT_DEBUGGER
(
    HOST            VARCHAR2,
    PORT            VARCHAR2,
    DEBUG_ROLE      VARCHAR2 := NULL,
    DEBUG_ROLE_PWD  VARCHAR2 := NULL,
    OPTION_FLAGS     PLS_INTEGER := 0,
    EXTENSIONS_CMD_SET PLS_INTEGER := 128
)
```

### Parameters

The preceding parameters are for the default implementation of the procedure for handling the debug connection request. A user, who wants to customize the handling of the request, must override this default implementation of the `DBMS_DEBUG_JDWP_CUSTOM` package procedure by defining the package (specification and body) with a procedure of the same name in the user's own schema. The user may customize the number and names of the arguments, but must have the same name for the package and the procedure, namely, `DBMS_DEBUG_JDWP_CUSTOM` and `CONNECT_DEBUGGER` respectively. The user's customized version of the package may contain overloaded versions of the `CONNECT_DEBUGGER` procedure with different arguments. All of the arguments to the custom package procedure must either be of `VARCHAR2` type or of types that PL/SQL can implicitly convert from `VARCHAR2`.

For example, if a user wants to disallow debugging outside business hours, while applying optional NLS settings to the program values displayed during debugging, then the user can define a custom implementation of the package in the user's schema in the following way:

```
CREATE OR REPLACE PACKAGE DBMS_DEBUG_JDWP_CUSTOM AUTHID CURRENT_USER IS
    PROCEDURE CONNECT_DEBUGGER(HOST VARCHAR2,
                               PORT VARCHAR2,
                               NLS_LANGUAGE VARCHAR2 DEFAULT NULL,
                               NLS_TERRITORY VARCHAR2 DEFAULT NULL);
END;
/

CREATE OR REPLACE PACKAGE BODY DBMS_DEBUG_JDWP_CUSTOM IS

    PROCEDURE CONNECT_DEBUGGER(HOST VARCHAR2,
                               PORT VARCHAR2,
                               NLS_LANGUAGE VARCHAR2 DEFAULT NULL,
                               NLS_TERRITORY VARCHAR2 DEFAULT NULL) IS
    BEGIN
        SELECT EXTRACT(HOUR FROM LOCALTIMESTAMP) INTO HOUR FROM DUAL;
        IF (HOUR < 9 OR HOUR > 5) THEN
            RAISE_APPLICATION_ERROR(-20000,
                'Debug connection disallowed outside business hours');
        END IF;
    END;
```

```
ELSE
  IF (NLS_LANGUAGE IS NOT NULL) THEN
    DBMS_DEBUG_JDWP.SET_NLS_PARAMETER('NLS_LANGUAGE', NLS_LANGUAGE);
  END IF;
  IF (NLS_TERRITORY IS NOT NULL) THEN
    DBMS_DEBUG_JDWP.SET_NLS_PARAMETER('NLS_TERRITORY', NLS_TERRITORY);
  END IF;
  DBMS_DEBUG_JDWP.CONNECT_TCP (HOST, PORT);
END IF;
END;

END;
/
```

Before executing the client application for passing arguments to the procedure parameters, the user must set the `ORA_DEBUG_JDWP` environment variable as follows :

```
> setenv ORA_DEBUG_JDWP "host=123.45.67.89;port=4000;nls_language=american"
> myapp -user HR/<password>
...
```

# 61

## DBMS\_DESCRIBE

You can use the `DBMS_DESCRIBE` package to get information about a PL/SQL object. When you specify an object name, `DBMS_DESCRIBE` returns a set of indexed tables with the results. Full name translation is performed and security checking is also checked on the final object.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Types](#)
- [Exceptions](#)
- [Examples](#)
- [Summary of DBMS\\_DESCRIBE Subprograms](#)

### 61.1 DBMS\_DESCRIBE Overview

This package provides the same functionality as the Oracle Call Interface `OCIDescribeAny` call.

#### See Also:

*Oracle Call Interface Programmer's Guide*

### 61.2 DBMS\_DESCRIBE Security Model

This package is available to `PUBLIC` and performs its own security checking based on the schema object being described.

### 61.3 DBMS\_DESCRIBE Types

The `DBMS_DESCRIBE` package declares two PL/SQL table types, which are used to hold data returned by `DESCRIBE_PROCEDURE` in its `OUT` parameters.

The types are:

```
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(30)
    INDEX BY BINARY_INTEGER;

TYPE NUMBER_TABLE IS TABLE OF NUMBER
    INDEX BY BINARY_INTEGER;
```

### 61.4 DBMS\_DESCRIBE Exceptions

`DBMS_DESCRIBE` can raise application errors in the range -20000 to -20004.

**Table 61-1 DBMS\_DESCRIBE Errors**

| Error     | Description                                                                   |
|-----------|-------------------------------------------------------------------------------|
| ORA-20000 | ORU 10035: cannot describe a package ('X') only a procedure within a package. |
| ORA-20001 | ORU-10032: procedure 'X' within package 'Y' does not exist.                   |
| ORA-20002 | ORU-10033: object 'X' is remote, cannot describe; expanded name 'Y'.          |
| ORA-20003 | ORU-10036: object 'X' is invalid and cannot be described.                     |
| ORA-20004 | Syntax error attempting to parse 'X'.                                         |

## 61.5 DBMS\_DESCRIBE Examples

One use of the DESCRIBE\_PROCEDURE procedure is as an external service interface.

For example, consider a client that provides an OBJECT\_NAME of SCOTT.ACCOUNT\_UPDATE, where ACCOUNT\_UPDATE is an overloaded function with specification:

```
TABLE account (acct_no NUMBER, person_id NUMBER,
               balance NUMBER(7,2))
TABLE person (person_id number(4), person_nm varchar2(10))

CREATE OR REPLACE PACKAGE ACCOUNT_PKG is
    FUNCTION ACCOUNT_UPDATE (acct_no    NUMBER,
                             person      person%rowtype,
                             amounts     DBMS_DESCRIBE.NUMBER_TABLE,
                             trans_date  DATE)
    return account.balance%type;

    FUNCTION ACCOUNT_UPDATE (acct_no    NUMBER,
                             person      person%rowtype,
                             amounts     DBMS_DESCRIBE.NUMBER_TABLE,
                             trans_no    NUMBER)
    return account.balance%type;
END;
```

This procedure might look similar to the following output:

| overload | position | argument   | level | datatype | length | prec | scale | rad |
|----------|----------|------------|-------|----------|--------|------|-------|-----|
| 1        | 0        |            | 0     | 2        | 22     | 7    | 2     | 10  |
| 1        | 1        | ACCT_NO    | 0     | 2        | 0      | 0    | 0     | 0   |
| 1        | 2        | PERSON     | 0     | 250      | 0      | 0    | 0     | 0   |
| 1        | 1        | PERSON_ID  | 1     | 2        | 22     | 4    | 0     | 10  |
| 1        | 2        | PERSON_NM  | 1     | 1        | 10     | 0    | 0     | 0   |
| 1        | 3        | AMOUNTS    | 0     | 251      | 0      | 0    | 0     | 0   |
| 1        | 1        |            | 1     | 2        | 22     | 0    | 0     | 0   |
| 1        | 4        | TRANS_DATE | 0     | 12       | 0      | 0    | 0     | 0   |
| 2        | 0        |            | 0     | 2        | 22     | 7    | 2     | 10  |
| 2        | 1        | ACCT_NO    | 0     | 2        | 22     | 0    | 0     | 0   |
| 2        | 2        | PERSON     | 0     | 2        | 22     | 4    | 0     | 10  |
| 2        | 3        | AMOUNTS    | 0     | 251      | 22     | 4    | 0     | 10  |
| 2        | 1        |            | 1     | 2        | 0      | 0    | 0     | 0   |
| 2        | 4        | TRANS_NO   | 0     | 2        | 0      | 0    | 0     | 0   |

The following PL/SQL procedure has as its parameters all of the PL/SQL datatypes:

```
CREATE OR REPLACE PROCEDURE p1 (
    pvc2    IN    VARCHAR2,
```

```

        pvc      OUT      VARCHAR,
        pstr     IN OUT   STRING,
        plong    IN       LONG,
        prowid   IN       ROWID,
        pchara   IN       CHARACTER,
        pchar    IN       CHAR,
        praw     IN       RAW,
        plraw    IN       LONG RAW,
        pbinint  IN       BINARY_INTEGER,
        pplsint  IN       PLS_INTEGER,
        pbool    IN       BOOLEAN,
        pnat     IN       NATURAL,
        ppos     IN       POSITIVE,
        pposn    IN       POSITIVEN,
        pnatn    IN       NATURALN,
        pnum     IN       NUMBER,
        pintgr   IN       INTEGER,
        pint     IN       INT,
        psmall   IN       SMALLINT,
        pdec     IN       DECIMAL,
        preal    IN       REAL,
        pfloat   IN       FLOAT,
        pnumer   IN       NUMERIC,
        pdp      IN       DOUBLE PRECISION,
        pdate    IN       DATE,
        pmls     IN       MLSLABEL) AS

BEGIN
    NULL;
END;
```

If you describe this procedure using the following:

```

CREATE OR REPLACE PACKAGE describe_it AS

    PROCEDURE desc_proc (name VARCHAR2);

END describe_it;

CREATE OR REPLACE PACKAGE BODY describe_it AS

    PROCEDURE prt_value(val VARCHAR2, isize INTEGER) IS
        n INTEGER;
    BEGIN
        n := isize - LENGTHB(val);
        IF n < 0 THEN
            n := 0;
        END IF;
        DBMS_OUTPUT.PUT(val);
        FOR i in 1..n LOOP
            DBMS_OUTPUT.PUT(' ');
        END LOOP;
    END prt_value;

    PROCEDURE desc_proc (name VARCHAR2) IS

        overload      DBMS_DESCRIBE.NUMBER_TABLE;
        position       DBMS_DESCRIBE.NUMBER_TABLE;
        c_level        DBMS_DESCRIBE.NUMBER_TABLE;
        arg_name        DBMS_DESCRIBE.VARCHAR2_TABLE;
        dtype          DBMS_DESCRIBE.NUMBER_TABLE;
        def_val         DBMS_DESCRIBE.NUMBER_TABLE;
```

```

p_mode      DBMS_DESCRIBE.NUMBER_TABLE;
length      DBMS_DESCRIBE.NUMBER_TABLE;
precision   DBMS_DESCRIBE.NUMBER_TABLE;
scale       DBMS_DESCRIBE.NUMBER_TABLE;
radix       DBMS_DESCRIBE.NUMBER_TABLE;
spare       DBMS_DESCRIBE.NUMBER_TABLE;
idx         INTEGER := 0;

BEGIN
  DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
    name,
    null,
    null,
    overload,
    position,
    c_level,
    arg_name,
    dtty,
    def_val,
    p_mode,
    length,
    precision,
    scale,
    radix,
    spare);

  DBMS_OUTPUT.PUT_LINE('Position      Name          DTY   Mode');
  LOOP
    idx := idx + 1;
    prt_value(TO_CHAR(position(idx)), 12);
    prt_value(arg_name(idx), 12);
    prt_value(TO_CHAR(dtty(idx)), 5);
    prt_value(TO_CHAR(p_mode(idx)), 5);
    DBMS_OUTPUT.NEW_LINE;
  END LOOP;
EXCEPTION
  WHEN NO_DATA_FOUND THEN
    DBMS_OUTPUT.NEW_LINE;
    DBMS_OUTPUT.NEW_LINE;

  END desc_proc;
END describe_it;

```

Then the results list all the numeric codes for the PL/SQL datatypes:

| Position | Name    | Datatype_Code | Mode |
|----------|---------|---------------|------|
| 1        | PVC2    | 1             | 0    |
| 2        | PVC     | 1             | 1    |
| 3        | PSTR    | 1             | 2    |
| 4        | PLONG   | 8             | 0    |
| 5        | PROWID  | 11            | 0    |
| 6        | PCHARA  | 96            | 0    |
| 7        | PCHAR   | 96            | 0    |
| 8        | PRAW    | 23            | 0    |
| 9        | PLRAW   | 24            | 0    |

## 61.6 Summary of DBMS\_DESCRIBE Subprograms

The DBMS\_DESCRIBE package includes the DESCRIBE\_PROCEDURE procedure.

**Table 61-2 DBMS\_DESCRIBE Package Subprograms**

| Subprogram                                   | Description                                               |
|----------------------------------------------|-----------------------------------------------------------|
| <a href="#">DESCRIBE_PROCEDURE Procedure</a> | Provides a brief description of a PL/SQL stored procedure |

### 61.6.1 DESCRIBE\_PROCEDURE Procedure

The procedure DESCRIBE\_PROCEDURE provides a brief description of a PL/SQL stored procedure.

It takes the name of a stored procedure and returns information about each parameter of that procedure.

#### Syntax

```
DBMS_DESCRIBE.DESCRIBE_PROCEDURE (
    object_name          IN  VARCHAR2,
    reserved1            IN  VARCHAR2,
    reserved2            IN  VARCHAR2,
    overload             OUT NUMBER_TABLE,
    position             OUT NUMBER_TABLE,
    level               OUT NUMBER_TABLE,
    argument_name        OUT VARCHAR2_TABLE,
    datatype             OUT NUMBER_TABLE,
    default_value        OUT NUMBER_TABLE,
    in_out               OUT NUMBER_TABLE,
    length               OUT NUMBER_TABLE,
    precision            OUT NUMBER_TABLE,
    scale               OUT NUMBER_TABLE,
    radix                OUT NUMBER_TABLE,
    spare                OUT NUMBER_TABLE,
    include_string_constraints OUT BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 61-3 DBMS\_DESCRIBE.DESCRIBE\_PROCEDURE Parameters**

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_name   | <p>Name of the procedure being described.</p> <p>The syntax for this parameter follows the rules used for identifiers in SQL. The name can be a synonym. This parameter is required and may not be null. The total length of the name cannot exceed 197 bytes. An incorrectly specified OBJECT_NAME can result in one of the following exceptions:</p> <p>ORA-20000 - A package was specified. You can only specify a stored procedure, stored function, packaged procedure, or packaged function.</p> <p>ORA-20001 - The procedure or function that you specified does not exist within the given package.</p> <p>ORA-20002 - The object that you specified is a remote object. This procedure cannot currently describe remote objects.</p> <p>ORA-20003 - The object that you specified is invalid and cannot be described.</p> <p>ORA-20004 - The object was specified with a syntax error.</p> |
| reserved1     | Reserved for future use -- must be set to NULL or the empty string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| reserved2     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| overload      | <p>A unique number assigned to the procedure's signature.</p> <p>If a procedure is overloaded, then this field holds a different value for each version of the procedure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| position      | <p>Position of the argument in the parameter list.</p> <p>Position 0 returns the values for the return type of a function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| level         | If the argument is a composite type, such as record, then this parameter returns the level of the datatype. See the <i>Oracle Call Interface Programmer's Guide</i> for a description of the ODESSP call for an example.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| argument_name | Name of the argument associated with the procedure that you are describing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 61-3 (Cont.) DBMS\_DESCRIBE.DESCRIBE\_PROCEDURE Parameters**

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>datatype</code>                   | <p>Oracle datatype of the argument being described. The datatypes and their numeric type codes are:</p> <ul style="list-style-type: none"> <li>0 placeholder for procedures with no arguments</li> <li>1 VARCHAR, VARCHAR, STRING</li> <li>2 NUMBER, INTEGER, SMALLINT, REAL, FLOAT, DECIMAL</li> <li>3 BINARY_INTEGER, PLS_INTEGER, POSITIVE, NATURAL</li> <li>8 LONG</li> <li>11 ROWID</li> <li>12 DATE</li> <li>23 RAW</li> <li>24 LONG RAW</li> <li>58 OPAQUE TYPE</li> <li>96 CHAR (ANSI FIXED CHAR), CHARACTER</li> <li>106 MLSLABEL</li> <li>121 OBJECT</li> <li>122 NESTED TABLE</li> <li>123 VARRAY</li> <li>178 TIME</li> <li>179 TIME WITH TIME ZONE</li> <li>180 TIMESTAMP</li> <li>181 TIMESTAMP WITH TIME ZONE</li> <li>231 TIMESTAMP WITH LOCAL TIME ZONE</li> <li>250 PL/SQL RECORD</li> <li>251 PL/SQL TABLE</li> <li>252 PL/SQL BOOLEAN</li> </ul> |
| <code>default_value</code>              | 1 if the argument being described has a default value; otherwise, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>in_out</code>                     | <p>Describes the mode of the parameter:</p> <ul style="list-style-type: none"> <li>0 IN</li> <li>1 OUT</li> <li>2 IN OUT</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>length</code>                     | For %rowtype formal arguments, the length constraint is returned, otherwise 0 is returned. If the <code>include_string_constraints</code> parameter is set to TRUE, the argument's formal length constraint is passed back if it is of the appropriate type. Those are the string types: 1;8;23;24;96                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>precision</code>                  | If the argument being described is of datatype 2 (NUMBER), then this parameter is the precision of that number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>scale</code>                      | If the argument being described is of datatype 2 (NUMBER), then this parameter is the scale of that number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>radix</code>                      | If the argument being described is of datatype 2 (NUMBER), then this parameter is the radix of that number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>spare</code>                      | Reserved for future functionality.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>include_string_constraints</code> | The default is FALSE. If the parameter is set to TRUE, the arguments' formal type constraints is passed back if it is of the appropriate type. Those are the string types: 1;8;23;24;96                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Return Values

All values from `DESCRIBE_PROCEDURE` are returned in its OUT parameters. The datatypes for these are PL/SQL tables, to accommodate a variable number of parameters.

## DBMS\_DEVELOPER

The package `DBMS_DEVELOPER` provides simple and developer friendly methods to retrieve information about database objects.

This chapter contains the following topics:

- [DBMS\\_DEVELOPER Overview](#)
- [Summary of DBMS\\_DEVELOPER Subprograms](#)

### 62.1 DBMS\_DEVELOPER Overview

The package `DBMS_DEVELOPER` provides subprograms to retrieve information about database objects.

The `DBMS_DEVELOPER` package provides simple methods to retrieve relevant information about the database objects. This package is useful for developer tools and developers who would like to get information about the objects in the database, their shape, their structure, etc.

In terms of performance, the `DBMS_DEVELOPER` package retrieves information within few milliseconds.

### 62.2 DBMS\_DEVELOPER Security

This section lists the security restrictions related to `DBMS_DEVELOPER` package.

The function is executed with invoker rights. You will be allowed to access metadata for a database object **ONLY** if you are authorized to do a "describe" on the object. If a you do not have such authorization, an error will be raised and no metadata will be retrieved.

Here's a summary of privileges required:

- **Tables and Views:** You need **SELECT** or **READ** privileges on the table or view.
- **Indexes:** You need **SELECT** or **READ** privileges on the table on which the index is defined.
- **Synonyms:** You need **SELECT** or **READ** privileges on the synonym as well as the underlying object.

If you're describing objects in your own schema, no additional privilege is needed. However, if you're describing objects in another schema, you'll need at least the **SELECT** privilege on those objects.

If you are a DBA or have the **SELECT ANY TABLE**, **READ ANY TABLE**, and **SELECT ANY VIEW** system privilege, you can call `DBMS_DEVELOPER.GET_METADATA` on any table, index, or view in the database without needing explicit grants.

### 62.3 Summary of DBMS\_DEVELOPER Subprograms

The table lists the `DBMS_DEVELOPER` subprograms and briefly describes them.

The following table specifies the subprograms for DBMS\_DEVELOPER package and its brief description.

| Subprogram   | Description                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET_METADATA | The function takes information about the object including : name, object_type, schema, etag and produces the corresponding metadata in CLOB containing JSON-formatted text output. The level of information that needs to be produced in the output can be specified in the input parameter - level . |

## 62.3.1 GET\_METADATA Function

This section describes the syntax, input and output formats of the GET\_METADATA function.

This function takes information about the object and produces the corresponding metadata as a CLOB containing JSON-formatted text output.

### Syntax

```
DBMS_DEVELOPER.GET_METADATA (
name           IN VARCHAR2,
schema         IN VARCHAR2 DEFAULT NULL,
object_type    IN VARCHAR2 DEFAULT NULL,
level          IN VARCHAR2 DEFAULT 'TYPICAL'
etag           IN RAW        DEFAULT NULL)
RETURN CLOB;
```

**Table 62-1 Input Configuration Fields**

| Field       | Value                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name        | The object name. A synonym of the object name can also be provided. It is case sensitive and should be provided as it appears in the data dictionary.                                                                                                                                                                     |
| schema      | The schema name. The default is the current user. It is case sensitive and should be provided as it appears in the data dictionary.                                                                                                                                                                                       |
| object_type | The type of object that you want to be retrieved. This is optional as name resolution can also be done without specifying object_type.<br>Supported values: TABLE, INDEX, and VIEW                                                                                                                                        |
| level       | The level of detail. The default is TYPICAL.<br>Supported values: <ol style="list-style-type: none"> <li><b>BASIC</b> : Describes essential information.</li> <li><b>TYPICAL</b> : Includes more information of specified objects.</li> <li><b>ALL</b> : Provides the most comprehensive level of information.</li> </ol> |

**Table 62-1 (Cont.) Input Configuration Fields**

| Field | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etag  | <p>A unique identifier for a specific version of the document. This <code>etag</code> value lets an application determine whether the content of a particular version of a document is the same as that of another version.</p> <ol style="list-style-type: none"><li>1. If an <code>etag</code> is provided and it matches with current <code>etag</code>, the function returns an empty document.</li><li>2. If the <code>etag</code> of the document in the database does not match the <code>etag</code> that was provided, a new document is returned (along with the new embedded <code>etag</code>).</li></ol> |

`GET_METADATA` function will not return a JSON schema, instead, it will return a JSON document. Depending on the level of metadata you would like to retrieve, you can use the appropriate parameters for `GET_METADATA` function to obtain the desired metadata JSON document. Refer to [JSON Schema for Different Object and Sub-Object Types](#) to understand which schema you would need for your application.

### Examples

This section provides example usage for `DBMS_DEVELOPER.GET_METADATA` for different values of `object_type` and `level`.

1. Retrieving metadata for `level` set to `BASIC` and for `object_type` set to `TABLE` :

```
SQL> conn hr/hr
Connected.
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name =>
'EMPLOYEES',
level => 'BASIC')RETURNING CLOB PRETTY) from dual;
```

Executing this query would produce the following:

```
{
  "objectType" : "TABLE",
  "objectInfo" :
  {
    "name" : "EMPLOYEES",
    "schema" : "HR",
    "columns" :
    [
      {
        "name" : "EMPLOYEE_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 6
        }
      }
    ]
  }
}
```

```

    },
    {
      "name" : "FIRST_NAME",
      "notNull" : false,
      "dataType" :
      {
        "type" : "VARCHAR2",
        "length" : 20,
        "sizeUnits" : "BYTE"
      }
    },
    {
      "name" : "LAST_NAME",
      "notNull" : true,
      "dataType" :
      {
        "type" : "VARCHAR2",
        "length" : 25,
        "sizeUnits" : "BYTE"
      }
    },

## 2. Retrieving metadata for level set to TYPICAL and for object\_type set to VIEW:

```

SQL> conn hr/hr
Connected.
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name =>
'EMP_DETAILS_VIEW',
level => 'TYPICAL')RETURNING CLOB PRETTY) from dual;

```

Executing this query would produce the following:

```
{
  "objectType" : "VIEW",
  "objectInfo" :
  {
    "name" : "EMP_DETAILS_VIEW",
    "schema" : "HR",
    "columns" :
    [
      {
        "name" : "EMPLOYEE_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 6
        }
      },
      {
        "name" : "JOB_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "VARCHAR2",
          "length" : 10,
          "sizeUnits" : "BYTE"
        }
      },
      {
        "name" : "MANAGER_ID",
        "notNull" : false,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 6
        }
      },
      {
        "name" : "DEPARTMENT_ID",
        "notNull" : false,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 4
        }
      },
      {
        "name" : "LOCATION_ID",
        "notNull" : false,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 4
        }
      }
    ]
  }
}
```

```
{
  "name" : "COUNTRY_ID",
  "notNull" : false,
  "dataType" :

```

### 3. Retrieving metadata for level set to ALL and for object\_type set to VIEW:

```

SQL> conn hr/hr
Connected.
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name =>
'EMP_DETAILS_VIEW',
level => 'ALL')RETURNING CLOB PRETTY) from dual;

```

Executing this query would produce the following:

```

{
  "objectType" : "VIEW",
  "objectInfo" :
  {
    "name" : "EMP_DETAILS_VIEW",
    "schema" : "HR",
    "columns" :
    [
      {
        "name" : "EMPLOYEE_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 6
        }
      },
      {
        "name" : "JOB_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "VARCHAR2",
          "length" : 10,
          "sizeUnits" : "BYTE"
        }
      },
      {
        "name" : "MANAGER_ID",
        "notNull" : false,

```

```

        "dataType" :
        {
            "type" : "NUMBER",
            "precision" : 6
        }
    },
    {
        "name" : "DEPARTMENT_ID",
        "notNull" : false,
        "dataType" :
        {
            "type" : "NUMBER",
            "precision" : 4
        }
    },
    {
        "name" : "LOCATION_ID",
        "notNull" : false,
        "dataType" :
        {
            "type" : "NUMBER",
            "precision" : 4
        }
    },
    {
        "name" : "COUNTRY_ID",

            "sizeUnits" : "BYTE"
        }
    },
    {
        "name" : "CITY",
        "notNull" : true,
        "dataType" :
        {
            "type" : "VARCHAR2",
            "length" : 30,
            "sizeUnits" : "BYTE"
        }
    },
    {
        "name" : "STATE_PROVINCE",
        "notNull" : false,
        "dataType" :
        {
            "type" : "VARCHAR2",
            "length" : 25,
            "sizeUnits" : "BYTE"
        }
    }

```

```

    }
  },
  {
    "name" : "COUNTRY_NAME",
    "notNull" : false,
    "dataType" :
    {
      "type" : "VARCHAR2",
      "length" : 40,
      "sizeUnits" : "BYTE"
    }
  },
  {
    "name" : "REGION_NAME",
    "notNull" : false,
    "dataType" :
    {
      "type" : "VARCHAR2",
      "length" : 25,
      "sizeUnits" : "BYTE"
    }
  }
],
"readOnly" : true,
"constraints" :
[
  {
    "name" : "SYS_C007578",
    "constraintType" : "VIEW READONLY",
    "status" : "ENABLED",
    "deferrable" : false,
    "validated" : "NOT VALIDATED",

  }
],
"editioningView" : false
},
"etag" : "ED648644C063A29B04E2A65CFC2D2E76"
}

```

#### 4. Retrieving metadata for level set to ALL and for object\_type set to INDEX :

```

SQL> conn hr/hr
Connected.
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name =>
'EMP_EMP_ID_PK',
level => 'ALL')RETURNING CLOB PRETTY) from dual;

```

Executing this query would produce the following:

```

{
  "objectType" : "INDEX",
  "objectInfo" :
  {
    "name" : "EMP_EMP_ID_PK",

```

```

    "indexType" : "NORMAL",
    "owner" : "HR",
    "tableName" : "EMPLOYEES",
    "status" : "VALID",
    "columns" :
    [
      {
        "name" : "EMPLOYEE_ID",
        "notNull" : true,
        "dataType" :
        {
          "type" : "NUMBER",
          "precision" : 6
        },
        "isPk" : true,
        "isUk" : true,
        "isFk" : false,
        "numDistinct" : 107,
        "density" : 0.00934579439252336,
        "avgColLen" : 4,
        "lowValue" : "C202",
        "highValue" : "C20307",
        "hiddenColumn" : false
      }
    ],
    "uniqueness" : "UNIQUE",
    "lastAnalyzed" : "2025-05-09T06:44:31",
    "numRows" : 107,
    "sampleSize" : 107,
    "partitioned" : false,
    "distinctKeys" : 107,
    "compression" : "DISABLED",
    "segmentCreated" : "YES",
    "visibility" : "VISIBLE",
    "toBeDropped" : false
  },
  "etag" : "752F0B7990BD188863BBBB80D5248F35"
}

```

**5. Retrieving metadata where level and object\_type are not explicitly specified:**

```

SQL> conn hr/hr
Connected.
SQL>
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name => 'EMPLOYEES')
RETURNING CLOB PRETTY) from dual;

```

Even though the `object_type` is not specified, the name resolution happens under the hood. The name `object_type` corresponding to the `name => 'EMPLOYEES'` is determined to be `table`. So the JSON document is produced at the default typical level for the `table` `object_type`. The output JSON document corresponding to the above example is shown here :

```

{
  "objectType" : "TABLE",

```

```

"objectInfo" :
{
  "name" : "EMPLOYEES",
  "schema" : "HR",
  "columns" :
  [
    {
      "name" : "EMPLOYEE_ID",
      "notNull" : true,
      "dataType" :
      {
        "type" : "NUMBER",
        "precision" : 6
      },
      "isPk" : true,
      "isUk" : true,
      "isFk" : false
    },
    {
      "name" : "FIRST_NAME",
      "notNull" : false,
      "dataType" :
      {
        "type" : "VARCHAR2",
        "length" : 20,
        "sizeUnits" : "BYTE"
      },
      "isPk" : false,
      "isUk" : false,
      "isFk" : false
    },
    {
      "name" : "LAST_NAME",
      "notNull" : true,
      "dataType" :
      {
        "type" : "VARCHAR2",
        "length" : 25,
        "sizeUnits" : "BYTE"
      },
      "isPk" : false,
      "isUk" : false,
      "isFk" : false
    },
    {
      "name" : "EMAIL",
      "notNull" : true,
      "dataType" :
      {
        "type" : "VARCHAR2",
        "length" : 25,
        "sizeUnits" : "BYTE"
      },
      "isPk" : false,
      "isUk" : true,
      "isFk" : false
    }
  ]
}

```

```

    },
    {
      "name" : "PHONE_NUMBER",
      "notNull" : false,

        "validated" : "VALIDATED",
        "sysGeneratedName" : false,
        "referencedConstraintName" : "EMP_EMP_ID_PK",
        "referencedTable" : "EMPLOYEES",
        "referencedOwner" : "HR",
        "Action" : "RESTRICT",
        "referencedColumns" :
        [
            {
                "name" : "EMPLOYEE_ID"
            }
        ]
    }
]
},
"etag" : "250A14E4E687854657E7336BCE46432F"
}

```

6. Retrieving metadata when the specified etag matches the current etag would return an empty document :

```

SQL> conn hr/hr
Connected.
SQL>
SQL> SELECT JSON_SERIALIZE(dbms_developer.get_metadata(name => 'REGIONS',
etag => '9ADC6D08AE0D5C82C0188D53F3ECD5B9')RETURNING CLOB PRETTY) from
dual;

```

Executing this query would produce an empty JSON document :

```
{
}
```

### 62.3.1.1 JSON Schema for Different Object and Sub-Object Types

This section provides an overview to the different schema possible for various object types, sub-object types and levels.

The JSON Schema can be used as a reference by applications to parse the JSON document returned. If you are programming against a specific version of the database program, you use that specific version of the JSON schema for that database version, and that schema will always be the same. But, if you upgrade or downgrade to a different release, you will be using a different schema version and then you need to use that correct schema. If there is any change in the schema, the version number in the \$id field will be changed. Applications can rely on this number in case Oracle plans to revise the JSON schema in the future. Existing versions will remain unchanged, so applications will remain fully functional and unaffected by the updates.

- The detailed description of the JSON schema for the `object_type` TABLE at all levels is described in the section : [JSON Schema for Object Type : TABLE](#)
- The detailed description of the JSON schema for the `object_type` INDEX at all levels is described in the section : [JSON Schema for Object Type : INDEX](#)
- The detailed description of the JSON schema for the `object_type` VIEW at all levels is described in the section : [JSON Schema for Object Type : VIEW](#)
- The detailed description of the JSON schema for the sub-object type COLUMNS at all levels is described in the section : [JSON Schema for Sub-Object Type : columns](#)
- The detailed description of the JSON schema for the sub-object type CONSTRAINTS at all levels is described in the section : [JSON Schema for Sub-Object Type : constraints](#)

#### 62.3.1.1.1 JSON Schema for Object Type : TABLE

This section describes the JSON schema for the object type TABLE at all levels.

##### JSON Schema for TABLE Object Type in Tabular Form

**Table 62-2 JSON schema for object type : TABLE**

| FIELDS          | LEVELS |         |     |
|-----------------|--------|---------|-----|
|                 | BASIC  | TYPICAL | ALL |
| name            | ≤      | ≤       | ≤   |
| schema          | ≤      | ≤       | ≤   |
| columns         | ≤      | ≤       | ≤   |
| hasBeenAnalyzed |        | ≤       | ≤   |
| lastAnalyzed    |        | ≤       | ≤   |
| numRows         |        | ≤       | ≤   |
| sampleSize      |        | ≤       | ≤   |

**Table 62-2 (Cont.) JSON schema for object type : TABLE**

| FIELDS              |                                            | LEVELS |   |
|---------------------|--------------------------------------------|--------|---|
| avgRowLen           |                                            | ≤      | ≤ |
| clusterName         |                                            | ≤      | ≤ |
| clusterOwner        |                                            | ≤      | ≤ |
| external            |                                            | ≤      | ≤ |
| temporary           |                                            | ≤      | ≤ |
| indexes             |                                            | ≤      | ≤ |
| constraints         |                                            | ≤      | ≤ |
| segmentCreated      |                                            |        | ≤ |
| inMemory            |                                            |        | ≤ |
| compression         |                                            |        | ≤ |
| dependencies        |                                            |        | ≤ |
| authorizations      | grantee<br>privileges<br>name<br>grantable |        | ≤ |
| inMemoryPriority    |                                            |        | ≤ |
| inMemoryDistribute  |                                            |        | ≤ |
| inMemoryCompression |                                            |        | ≤ |
| inMemoryDuplicated  |                                            |        | ≤ |
| iotType             |                                            |        | ≤ |

**Note:**

The fields of the sub-objects `columns` and `constraints` varies depending on the choice of the `level`. The detailed information of the fields present in the sub-object `columns` is described in the section : [JSON Schema for Sub-Object Type : columns](#). The detailed information of the fields present in the sub-object `constraints` is described in the section : [JSON Schema for Sub-Object Type : constraints](#).

**JSON Schema for TABLE object type at level BASIC**

```
{
  "$schema": "https://json-schema.org/draft/2020-12/schema",

### 62.3.1.1.2 JSON Schema for Object Type : `VIEW`

This section describes the JSON schema for the object type `VIEW` at all levels.

#### JSON Schema for `VIEW` Object Type in Tabular Form

**Table 62-3 JSON Schema for `VIEW` Object Type**

| Fields         | LEVELS     |           |     |
|----------------|------------|-----------|-----|
|                | BASIC      | TYPICAL   | ALL |
| name           | ≤          | ≤         | ≤   |
| schema         | ≤          | ≤         | ≤   |
| columns        | ≤          | ≤         | ≤   |
| readOnly       |            | ≤         | ≤   |
| constraints    |            | ≤         | ≤   |
| editioningView |            |           | ≤   |
| authorizations | grantee    |           | ≤   |
|                | privileges | name      |     |
|                |            | grantable |     |

#### Note:

The fields of the sub-objects `columns` and `constraints` varies depending on the choice of the `level`. The detailed information of the fields present in the sub-object `columns` is described in the section : [JSON Schema for Sub-Object Type : `columns`](#). The detailed information of the fields present in the sub-object `constraints` is described in the section : [JSON Schema for Sub-Object Type : `constraints`](#).

#### JSON Schema for `VIEW` object type at level `BASIC`

```

{
  "$schema": "https://json-schema.org/draft/2020-12/schema",
  "$id": "https://oracle.com/schema/19.28/DBMS_DEVELOPER.GET_METADATA/BASIC/object_info/view",

| encryptedColumn |                            |        |         | ≤   |

**Note:**

Certain fields are required based on the value of the `type` field. The following table lists the required fields for each `type` value.

| Value of the <code>type</code> Field | Corresponding Required Columns |
|--------------------------------------|--------------------------------|
| NUMBER                               | precision and scale            |
| FLOAT                                | precision                      |

|                                                                            |                                                 |
|----------------------------------------------------------------------------|-------------------------------------------------|
| VARCHAR2                                                                   | size and sizeUnits                              |
| RAW                                                                        | size                                            |
| CHAR                                                                       | size and sizeUnits                              |
| NCHAR                                                                      | size                                            |
| UROWID                                                                     | size                                            |
| NVARCHAR2                                                                  | size                                            |
| TIMESTAMP or TIMESTAMP WITH TIME ZONE or<br>TIMESTAMP WITH LOCAL TIME ZONE | fractionalSecondsPrecision                      |
| INTERVAL YEAR TO MONTH                                                     | yearPrecision                                   |
| INTERVAL DAY TO SECOND                                                     | yearPrecision and<br>fractionalSecondsPrecision |

#### 62.3.1.1.5 JSON Schema for Sub-Object Type : constraints

JSON schema for the sub-object constraints for the levels: typical and all.

#### JSON Schema for constraints Sub-Object Type in Tabular Form

**Table 62-6 JSON Schema for Sub-Object Type : CONSTRAINTS**

| Fields                   |       |         |     |
|--------------------------|-------|---------|-----|
|                          | BASIC | TYPICAL | ALL |
| name                     |       | ≤       | ≤   |
| constraintType           |       | ≤       | ≤   |
| searchCondition          |       | ≤       | ≤   |
| columns name             |       | ≤       | ≤   |
| referencedConstraintName |       | ≤       | ≤   |
| referencedTable          |       | ≤       | ≤   |
| action                   |       | ≤       | ≤   |
| referencedOwner          |       | ≤       | ≤   |
| referencedColumns name   |       | ≤       | ≤   |
| status                   |       | ≤       | ≤   |
| deferrable               |       | ≤       | ≤   |
| validated                |       | ≤       | ≤   |
| sysGeneratedName         |       | ≤       | ≤   |

**Note:**

If the `constraintType` is set to `REFERENTIAL INTEGRITY`, the following fields are required in the schema: `referencedConstraintName`, `referencedOwner`, `referencedTable`, and `referencedColumns`.

**Note:**

Constraint schema is not available for the `BASIC` level.

**JSON Schema for CONSTRAINT sub-object type at level TYPICAL**

## DBMS\_DG

The `DBMS_DG` package allows applications to notify the primary database or the fast-start failover target database in an Oracle Data Guard broker environment to initiate a fast-start failover when the application encounters a condition that warrants a failover.

This chapter contains the following topics:

- [Using DBMS\\_DG](#)
- [Security Model](#)
- [Summary of the DBMS\\_DG Subprogram](#)

### See Also:

*Oracle Data Guard Broker*

### 63.1 Using DBMS\_DG

There are conditions detectable by applications running outside of the Oracle database that may warrant the Oracle Data Guard broker to perform a fast-start failover. Because the range of possible conditions is virtually unlimited, it is left to the applications to determine which conditions warrant a fast-start failover.

When such conditions occur, the application calls the `DBMS_DG.INITIALIZE_FS_FAILOVER` procedure to alert either the primary or fast-start failover target standby database that the application wants a fast-start failover to occur immediately. The database on which the procedure was called then notifies the observer, which immediately initiates a fast-start failover as long as the standby database is in a valid fast-start failover state ("observed" and either "synchronized" or "within lag") to accept a failover. If the configuration is not in a valid fast-start failover state, the `INITIALIZE_FS_FAILOVER` subprogram returns an ORA error message (it will not signal an exception) to inform the calling application that a fast-start failover could not be performed.

### Note:

If you are working in a multitenant container database (CDB), then functions within `DBMS_DG` are only executed at the root level. Ensure you are connected at the root level, not at the individual pluggable database (PDB) level.

### 63.2 DBMS\_DG Security Model

The `DBMS_DG` package runs with invoker's rights and requires the `SYSDBA` privilege.

## 63.3 Summary of the DBMS\_DG Subprogram

The DBMS\_DG package contains one subprogram, the `INITIATE_FS_FAILOVER` procedure.

**Table 63-1 DBMS\_DG Package Subprogram**

| Subprogram                                     | Description                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">INITIATE_FS_FAILOVER Procedure</a> | Enables an application to notify either the primary or fast-start failover target standby database that a fast-start failover is necessary when the application encounters conditions that warrant a failover. This procedure can only be called while connected to a primary database or a fast-start failover standby database. |

### 63.3.1 INITIATE\_FS\_FAILOVER Procedure

Use this procedure to specify a condition string that, when encountered by an application, allows the application to request that a fast-start failover be invoked.

#### Syntax

```
DBMS_DG.INITIATE_FS_FAILOVER (  
    condstr          IN VARCHAR2)  
RETURN BINARY_INTEGER;
```

#### Parameters

**Table 63-2 INITIATE\_FS\_FAILOVER Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| condstr   | Specifies the condition string for which a fast-start failover should be requested. If no condition string argument is supplied, the default string of "Application Failover Requested" will be logged in the broker log file and in the database alert log of the database on which the procedure was called. |

#### Usage Notes

- This procedure returns a binary integer.
- Query the `V$FS_FAILOVER_STATS` view to see the time of the last fast-start failover and the reason it was performed.
- This procedure can only be called while connected to a primary database or a fast-start failover standby database.

#### Errors

**Table 63-3 INITIATE\_FS\_FAILOVER Procedure Errors**

| Error                                    | Description                                                                    |
|------------------------------------------|--------------------------------------------------------------------------------|
| ORA-00000: normal, successful completion | The request to initiate a fast-start failover has been posted to the observer. |

**Table 63-3 (Cont.) INITIATE\_FS\_FAILOVER Procedure Errors**

| Error                                                                             | Description                                                                                                                                                                 |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-16646: fast-start failover is disabled                                        | Either a broker configuration does not exist or fast-start failover has not been enabled.                                                                                   |
| ORA-16666: unable to initiate fast-start failover on a bystander standby database | DBMS_DG.INITIATE_FS_FAILOVER was invoked on a bystander standby database. That is, it was not invoked on the primary or on the fast-start failover target standby database. |
| ORA-16817: unsynchronized fast-start failover configuration                       | DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum available fast-start failover configuration when the configuration was not synchronized.                              |
| ORA-16819: fast-start failover observer not started                               | DBMS_DG.INITIATE_FS_FAILOVER was invoked but an observer had not yet been started.                                                                                          |
| ORA-16820: fast-start failover observer is no longer observing this database      | DBMS_DG.INITIATE_FS_FAILOVER was invoked but the configuration detects that the observer may not be running.                                                                |
| ORA-16829: lagging fast-start failover configuration                              | DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum performance fast-start failover configuration when the configuration was not in the user-specified redo lag limit.    |

### Example

In this example, the program attempts to initiate a fast-start failover when fast-start failover is disabled. To use this example, connect as user SYS with SYDDBA privileges.

```

set serveroutput on

declare
status integer;

begin
status := dbms_dg.initiate_fs_failover('Failover Requested');

dbms_output.put_line('Fast-Start Failover is disabled: Expected status = ORA-16646');
dbms_output.put_line('          Actual Status = ORA-' || status);

end;
/
exit;
```

# DBMS\_DICTIONARY\_CHECK

`DBMS_DICTIONARY_CHECK` is a read-only and lightweight PL/SQL package procedure that helps you identify Oracle Database dictionary inconsistencies.

## 64.1 Overview of Oracle Database Dictionary Check

`DBMS_DICTIONARY_CHECK` is a read-only and lightweight PL/SQL package procedure that helps you identify Oracle Database dictionary inconsistencies that are manifested in unexpected entries in the Oracle Database dictionary tables or invalid references between dictionary tables. Oracle Database dictionary inconsistencies can cause process failures and, in some cases, instance crash. Such inconsistencies may be exposed to internal `ORA-00600` errors. `DBMS_DICTIONARY_CHECK` assists you in identifying such inconsistencies and in some cases provides guided remediation to resolve the problem and avoid such database failures.

Unexpected entries in the dictionary tables or invalid references between dictionary tables, for example, include the following:

- A lob segment not in `OBJ$`
- An entry in `SOURCE$` not in `OBJ$`
- Invalid data between `OBJ$-PARTOBJ$` and `TABPART$`
- A segment with no owner
- A materialized segment with no entry in `seg$`
- A segment with no object entry
- A recycle bin object not in the `recyclebin$`
- Check if `Control Seq` is near the limit

## 64.2 Using DBMS\_DICTIONARY\_CHECK

To run all the checks or only the critical checks defined by `DBMS_DICTIONARY_CHECK`, connect to the `SYS` schema, and then run the following commands as `SYS` user:

### Full check

```
SQL> set serveroutput on size unlimited
SQL> execute dbms_dictionary_check.full
```

### Critical check

```
SQL> set serveroutput on size unlimited
SQL> execute dbms_dictionary_check.critical
```

Optionally, turn on the spool to redirect the output to a server-side flat file. By default, when you query the SYS schema, the DBMS\_DICTIONARY\_CHECK package creates a trace file named, DICTCHECK.trc.

For example: /<path>/diag/rdbms/<db\_name>/<oracle\_sid>/trace/  
<oracle\_sid>\_<ora>\_<pid>\_DICTCHECK.trc.

The execution reports the result as:

- **CRITICAL:** Requires an immediate fix.
- **FAIL:** Requires resolution on priority.
- **WARN:** Good to resolve.
- **PASS:** No issues.

#### Note:

In all cases, any output reporting "problems" must be triaged by Oracle Support to confirm if any action is required.

### Example 64-1 Full check run

```
SQL> set serveroutput on size unlimited
SQL> execute dbms_dictionary_check.full
dbms_dictionary_check on 07-MAR-2023
03:17:48
```

-----

```
Catalog Version 19.0.0.0.0
(1900000000)
db_name:
ORCL
```

```
Is CDB?:
NO
```

```
Trace File: /oracle/log/diag/rdbms/orcl/orcl/trace/
orcl_ora_2574906_DICTCHECK.trc
```

## 64.3 Summary of DBMS\_DICTIONARY\_CHECK Subprograms

DBMS\_DICTIONARY\_CHECK package includes the following procedures:

- **LobNotInObj**: Checks if a LOB segment is not in OBJ\$ (My Oracle Support Note [1360208.1](#))

- **OIDOnObjCol**: Checks if an object type column is not in `OID$` (My Oracle Support Note [1360268.1](#))
- **SourceNotInObj**: Checks if an entry in `SOURCE$` is not in `OBJ$` (My Oracle Support Note [1360233.1](#))  
While running the `SourceNotInObj` procedure, optionally, you can use the `repair` option to resolve inconsistencies. Valid values: `TRUE|FALSE`. Default: `FALSE`.
- **IndIndparMismatch**: Checks for index name mismatch between partitions (My Oracle Support Note [1360285.1](#))
- **InvCorrAudit**: Checks for invalid `AUDIT$` entries (My Oracle Support Note [1360489.1](#))
- **OversizedFiles**: Checks for oversized database files (My Oracle Support Note [1360490.1](#))
- **PoorDefaultStorage**: Checks tablespace default storage clauses (My Oracle Support Note [1360493.1](#))
- **PoorStorage**: Checks objects storage clause (My Oracle Support Note [1360496.1](#))
- **PartSubPartMismatch**: Checks valid partition methods (My Oracle Support Note [1360504.1](#))
- **TabPartCountMismatch**: Checks invalid data between `OBJ$-PARTOBJ$` and `TABPART$` (My Oracle Support Note [1360514.1](#))
- **TabComPartObj**: Checks that the composite partition has a valid entry in `OBJ$` (My Oracle Support Note [1360515.1](#))
- **Mview**: Check invalid entries for materialized view (My Oracle Support Note [1360517.1](#))
- **ValidDir**: Checks that the directory object has valid entries (My Oracle Support Note [1360518.1](#))
- **DuplicateDataobj**: Checks for duplicate segment `data_object_id` (My Oracle Support Note [1360519.1](#))
- **ObjSyn**: Checks that a synonym has a valid entry in `OBJ$` (My Oracle Support Note [1360520.1](#))
- **ObjSeq**: Checks that a sequence has a valid entry in `OBJ$` (My Oracle Support Note [1360524.1](#))
- **UndoSeg**: Checks that undo segment has a valid entry in `SEG$` (My Oracle Support Note [1360527.1](#))
- **IndexSeg**: Checks that an index segment has a valid entry in `SEG$` (My Oracle Support Note [1360531.1](#))
- **IndexPartitionSeg**: Checks that an index partition has a valid entry in `SEG$` (My Oracle Support Note [1360535.1](#))
- **IndexSubPartitionSeg**: Checks that an index sub-partition has a valid entry in `SEG$` (My Oracle Support Note [1360536.1](#))
- **TableSeg**: Checks that a table has a valid entry in `SEG$` (My Oracle Support Note [1360889.1](#))
- **TablePartitionSeg**: Checks that a table partition has a valid entry in `SEG$` (My Oracle Support Note [1360890.1](#))
- **TableSubPartitionSeg**: Checks that a table sub-partition has a valid entry in `SEG$` (My Oracle Support Note [1360891.1](#))
- **PartCol**: Checks for valid entry of column partition (My Oracle Support Note [1360892.1](#))

- **ValidateSeg:** Checks that a segment in SEG\$ has an entry in its parent (My Oracle Support Note [1360934.1](#))  
While running the ValidateSeg procedure, optionally, you can use the repair option to resolve inconsistencies. Valid values: TRUE|FALSE. Default: FALSE.
- **IndPartObj:** Checks that an index partition has an entry in OBJ\$ (My Oracle Support Note [1360935.1](#))
- **DuplicateBlockUse:** Checks for a segment header block is used by only one segment (My Oracle Support Note [1360880.1](#))
- **FetUet:** Checks valid free/used space in a dictionary-managed tablespace (My Oracle Support Note [1360882.1](#))
- **Uet0Check:** Checks valid first extent in a dictionary-managed tablespace (My Oracle Support Note [1360883.1](#))
- **ExtentlessSeg:** Checks SEG\$/UET\$ mismatch in a dictionary-managed tablespace (My Oracle Support Note [1360944.1](#))
- **SeglessUET:** Checks UET\$/SEG\$ mismatch in a dictionary-managed tablespace (My Oracle Support Note [1360944.1](#))
- **ValidInd:** Checks that an index in OBJ\$ has a corresponding entry in the index dictionary (My Oracle Support Note [1360528.1](#))
- **ValidTab:** Checks that a table in OBJ\$ has a corresponding entry in TAB\$ (My Oracle Support Note [1360538.1](#))
- **IcolDepCnt:** Checks valid entries in ICOLDEP\$ (My Oracle Support Note [1360938.1](#))
- **WarnIcolDep:** Checks that an index does not have an ADT (object column) (My Oracle Support Note [1360939.1](#))
- **ObjIndDobj:** Checks index data\_object\_id mismatch between OBJ\$ and IND\$ (My Oracle Support Note [1360968.1](#))
- **TrgAfterUpgrade:** Checks valid entries in triggers (My Oracle Support Note [1361014.1](#))
- **ObjType0:** Checks that OBJ\$ has a valid type greater than 0 (My Oracle Support Note [1361015.1](#))
- **ValidOwner:** Checks that an entry in OBJ\$ has a valid user ID (My Oracle Support Note [1361020.1](#))
- **StmtAuditOnCommit:** Checks valid entries for STMT\_AUDIT\_OPTION\_MAP (My Oracle Support Note [1361021.1](#))
- **PublicObjects:** Checks that objects are not owned by PUBLIC (My Oracle Support Note [1361022.1](#))
- **SegFreelist:** Checks that a LOB segment has a valid free list group (My Oracle Support Note [1361023.1](#))
- **ValidDepends:** Checks for valid dependency timestamps (My Oracle Support Note [1361045.1](#))
- **CheckDual:** Checks valid entries in DUAL (My Oracle Support Note [1361046.1](#))
- **ObjectNames:** Checks if an object has the same name as its schema owner (My Oracle Support Note [2363142.1](#))
- **CboHiLo:** Checks for valid entries in histograms (My Oracle Support Note [1361047.1](#))
- **ChkIotTs:** Checks that an IOT object does not have a segment (My Oracle Support Note [1361048.1](#))

- **NoSegmentIndex**: Checks for NOSEGMENT indexes (My Oracle Support Note [1361049.1](#))
- **NextObject**: Checks for valid data\_object\_id (My Oracle Support Note [2124772.1](#))
- **DroppedROTS**: Checks for valid entries in a read-only tablespace (My Oracle Support Note [2124774.1](#))
- **FilBlkZero**: Checks for zero data block address (My Oracle Support Note [2124783.1](#))
- **DbmsSchemaCopy**: Checks for invalid execution of DBMS\_SCHEMA\_COPY (My Oracle Support Note [2124795.1](#))
- **IdnseqObj**: Checks that Identity column has a valid object (My Oracle Support Note [2124805.1](#))
- **IdnseqSeq**: Checks that a sequence has a valid object (My Oracle Support Note [2124787.1](#))
- **ObjError**: Checks that an object error is valid (My Oracle Support Note [2124788.1](#))
- **ObjNotLob**: Checks that a LOB object has an entry in LOB\$ (My Oracle Support Note [2125104.1](#))
- **MaxControlfSeq**: Checks if Control Seq is near the limit (My Oracle Support Note [2128446.1](#))
- **SegNotInDeferredStg**: Checks for an invalid deferred segment (My Oracle Support Note [2298947.1](#))
- **SystemNotRfile1**: Checks that the system tablespace has a relative file number 1 (My Oracle Support Note [2364065.1](#))
- **DictOwnNonDefaultSYSTEM**: Checks that the users SYS and SYSTEM have default tablespace SYSTEM (My Oracle Support Note [2377270.1](#))
- **ValidateTrigger**: Checks that triggers have valid entries in their parents (My Oracle Support Note [2384373.1](#))
- **ObjNotTrigger**: Checks if an object trigger is not in TRIGGER\$ (My Oracle Support Note [2384392.1](#))
- **WarningTSMaXSCN**: Checks exposed SCN entries in tablespaces
- **InvalidTSMaXSCN**: Checks for invalid SCN entries in tablespaces (My Oracle Support Note [1360208.1](#))
- **OBJRecycleBin**: Checks that recycle bin objects in OBJ\$ exist in RECYCLEBIN\$ (My Oracle Support Note [2902943.1](#))
- **LobSeg**: Checks that a LOB segment has a valid entry in SEG\$ (My Oracle Support Note [2948392.1](#) and [2948408.1](#))
- **ObjLogicalConstraints**: Checks logical constraints in OBJ\$ (My Oracle Support Note [2977609.1](#) and Note [2977591.1](#))
- **Critical**: Executes only critical checks
- **Full**: Executes all checks

# DBMS\_DIMENSION

DBMS\_DIMENSION enables you to verify dimension relationships and provides an alternative to the Enterprise Manager Dimension Wizard for displaying a dimension definition.

 **See Also:**

Oracle Database Data Warehousing Guide for detailed conceptual and usage information about the DBMS\_DIMENSION package

This chapter contains the following topics:

- [Security Model](#)
- [Summary of DBMS\\_DIMENSION Subprograms](#)

## 65.1 DBMS\_DIMENSION Security Model

Security on this package can be controlled by granting EXECUTE to selected users or roles.

A user can validate or describe all the dimensions in his own schema. To validate or describe a dimension in another schema, you must have either an object privilege on the dimension or one of the following system privileges: CREATE ANY DIMENSION, ALTER ANY DIMENSION, and DROP ANY DIMENSION.

## 65.2 Summary of DBMS\_DIMENSION Subprograms

This table lists the DBMS\_DIMENSION subprograms and briefly describes them.

**Table 65-1 DBMS\_DIMENSION Package Subprograms**

| Subprogram                                   | Description                                                                                                               |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DESCRIBE_DIMENSION Procedure</a> | Prints out the definition of the input dimension, including dimension owner and name, levels, hierarchies, and attributes |
| <a href="#">VALIDATE_DIMENSION Procedure</a> | Verifies that the relationships specified in a dimension are correct                                                      |

### 65.2.1 DESCRIBE\_DIMENSION Procedure

This procedure displays the definition of the dimension, including dimension name, levels, hierarchies, and attributes. It displays the output using the DBMS\_OUTPUT package.

**Syntax**

```
DBMS_DIMENSION.DESCRIBE_DIMENSION (  
    dimension IN VARCHAR2);
```

## Parameters

**Table 65-2 DESCRIBE\_DIMENSION Procedure Parameter**

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| dimension | The owner and name of the dimension in the format of owner.name. |

## 65.2.2 VALIDATE\_DIMENSION Procedure

This procedure verifies that the relationships specified in a dimension are valid. The rowid for any row that is found to be invalid will be stored in the table `DIMENSION_EXCEPTIONS` in the user's schema.

### Syntax

```
DBMS_DIMENSION.VALIDATE_DIMENSION (  
    dimension          IN VARCHAR2,  
    incremental        IN BOOLEAN := TRUE,  
    check_nulls        IN BOOLEAN := FALSE,  
    statement_id       IN VARCHAR2 := NULL );
```

## Parameters

**Table 65-3 VALIDATE\_DIMENSION Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dimension    | The owner and name of the dimension in the format of owner.name.                                                                                                                             |
| incremental  | If TRUE, check only the new rows for tables of this dimension. If FALSE, check all the rows.                                                                                                 |
| check_nulls  | If TRUE, then all level columns are verified to be non-null.<br>If FALSE, this check is omitted. Specify FALSE when non-NULLness is guaranteed by other means, such as NOT NULL constraints. |
| statement_id | A client-supplied unique identifier to associate output rows with specific invocations of the procedure.                                                                                     |

# DBMS\_DISTRIBUTED\_TRUST\_ADMIN

DBMS\_DISTRIBUTED\_TRUST\_ADMIN procedures maintain the Trusted Servers List. Use these procedures to define whether a server is trusted. If a database is not trusted, Oracle refuses current user database links from the database.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Examples](#)
- [Summary of DBMS\\_DISTRIBUTED\\_TRUST\\_ADMIN Subprograms](#)

## 66.1 DBMS\_DISTRIBUTED\_TRUST\_ADMIN Overview

Oracle uses local Trusted Servers Lists, along with enterprise domain membership lists stored in the enterprise LDAP directory service, to determine if another database is trusted. The LDAP directory service entries are managed with the Enterprise Security Manager Tool in Oracle Enterprise Manager.

Oracle considers another database to be "trusted" if it meets the following criteria:

1. It is in the same enterprise domain in the directory service as the local database.
2. The enterprise domain is marked as trusted in the directory service.
3. It is not listed as untrusted in the local Trusted Servers List. Current user database links will only be accepted from another database if both databases involved trust each other.

You can list a database server locally in the Trusted Servers List regardless of what is listed in the directory service. However, if you list a database that is not in the same domain as the local database, or if that domain is untrusted, the entry will have no effect.

This functionality is part of the Enterprise User Security feature of the Oracle Advanced Security Option.

## 66.2 DBMS\_DISTRIBUTED\_TRUST\_ADMIN Security Model

To execute DBMS\_DISTRIBUTED\_TRUST\_ADMIN, the EXECUTE\_CATALOG\_ROLE role must be granted to the DBA. To select from the view TRUSTED\_SERVERS, the SELECT\_CATALOG\_ROLE role must be granted to the DBA.

It is important to know whether all servers are trusted or not trusted. Trusting a particular server with the ALLOW\_SERVER procedure does not have any effect if the database already trusts all databases, or if that database is already trusted. Similarly, denying a particular server with the DENY\_SERVER procedure does not have any effect if the database already does not trust any database or if that database is already untrusted.

The procedures DENY\_ALL and ALLOW\_ALL delete all entries (in other words, server names) that are explicitly allowed or denied using the ALLOW\_SERVER procedure or DENY\_SERVER procedure respectively.

## 66.3 DBMS\_DISTRIBUTED\_TRUST\_ADMIN Examples

If you have not yet used the package `DBMS_DISTRIBUTED_TRUST_ADMIN` to change the trust listing, by default you trust all databases in the same enterprise domain if that domain is listed as trusted in the directory service:

```
SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
-----
Trusted
All
```

Because all servers are currently trusted, you can execute the [DENY\\_SERVER Procedure](#) and specify that a particular server is not trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER
        ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
-----
Untrusted SALES.US.AMERICAS.ACME_AUTO.COM
```

By executing the [DENY\\_ALL Procedure](#), you can choose to not trust any database server:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;

PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;

TRUST
NAME
-----
Untrusted
All
```

The [ALLOW\\_SERVER Procedure](#) can be used to specify that one particular database is to be trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER
        ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
-----
Trusted   SALES.US.AMERICAS.ACME_AUTO.COM
```

## 66.4 Summary of DBMS\_DISTRIBUTED\_TRUST\_ADMIN Subprograms

This table lists and briefly describes the `DBMS_DISTRIBUTED_TRUST_ADMIN` subprograms.

**Table 66-1 DBMS\_DISTRIBUTED\_TRUST\_ADMIN Package Subprograms**

| Subprogram                             | Description                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">ALLOW_ALL Procedure</a>    | Empties the list and inserts a row indicating that all servers should be trusted             |
| <a href="#">ALLOW_SERVER Procedure</a> | Enables a specific server to be allowed access even though deny all is indicated in the list |
| <a href="#">DENY_ALL Procedure</a>     | Empties the list and inserts a row indicating that all servers should be untrusted           |
| <a href="#">DENY_SERVER Procedure</a>  | Enables a specific server to be denied access even though allow all is indicated in the list |

## 66.4.1 ALLOW\_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers that are members of a trusted domain in an enterprise directory service and that are in the same domain are allowed access.

The view `TRUSTED_SERVERS` will show "TRUSTED ALL" indicating that the database trusts all servers that are currently trusted by the enterprise directory service.

### Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_ALL;
```

### Usage Notes

`ALLOW_ALL` only applies to servers listed as trusted in the enterprise directory service and in the same enterprise domain.

## 66.4.2 ALLOW\_SERVER Procedure

This procedure ensures that the specified server is considered trusted (even if you have previously specified "deny all").

### Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER (
    server IN VARCHAR2);
```

### Parameters

**Table 66-2 ALLOW\_SERVER Procedure Parameters**

| Parameter           | Description                                               |
|---------------------|-----------------------------------------------------------|
| <code>server</code> | Unique, fully-qualified name of the server to be trusted. |

### Usage Notes

If the Trusted Servers List contains the entry "deny all", then this procedure adds a specification indicating that a specific database (for example, `DBX`) is to be trusted.

If the Trusted Servers List contains the entry "allow all", and if there is no "deny DBx" entry in the list, then executing this procedure causes no change.

If the Trusted Servers List contains the entry "allow all", and if there is a "deny DBx" entry in the list, then that entry is deleted.

### 66.4.3 DENY\_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers are denied access.

The view TRUSTED\_SERVERS will show "UNTRUSTED ALL" indicating that no servers are currently trusted.

#### Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;
```

### 66.4.4 DENY\_SERVER Procedure

This procedure ensures that the specified server is considered untrusted (even if you have previously specified allow all).

#### Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER (
    server IN VARCHAR2);
```

#### Parameters

**Table 66-3 DENY\_SERVER Procedure Parameters**

| Parameter | Description                                                 |
|-----------|-------------------------------------------------------------|
| server    | Unique, fully-qualified name of the server to be untrusted. |

#### Usage Notes

If the Trusted Servers List contains the entry allow all, then this procedure adds an entry indicating that the specified database (for example, DBx) is not to be trusted.

If the Trusted Servers List contains the entry "deny all", and if there is no "allow DBx" entry in the list, then this procedure causes no change.

If the Trusted Servers List contains the entry "deny all", and if there is an "allow DBx" entry, then this procedure causes that entry to be deleted.

## DBMS\_DNFS

The `DBMS_DNFS` package provides an interface to assists in creating a database using files in the backup set.

This chapter contains the following topics:

- [Security Model](#)
- [Summary of DBMS\\_DNFS Subprograms](#)

### See Also:

*Oracle Database Administrator's Guide*

## 67.1 DBMS\_DNFS Security Model

This package has to be executed by users with `SYSDBA` privileges.

## 67.2 Summary of DBMS\_DNFS Subprograms

The `DBMS_DNFS` package includes the `CLONEDB_RENAMEFILE`, `RESTORE_DATAFILE_PERMISSIONS`, and `UNMOUNTVOLUME` procedures.

**Table 67-1 DBMS\_DNFS Package Subprograms**

| Subprogram                                             | Description                                                                                                                                                                                                  |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CLONEDB_RENAMEFILE Procedure</a>           | Renames datafiles that were pointing to the backup set to the actual file name in cloned database.                                                                                                           |
| <a href="#">RESTORE_DATAFILE_PERMISSIONS Procedure</a> | This procedure will restore the file permissions for the data files belonging to the PDB to read write. PDB data files are converted to read only when one or more clones are created using this source PDB. |
| <a href="#">UNMOUNTVOLUME Procedure</a>                | This procedure cleans up the cached Direct NFS file handles in SGA.                                                                                                                                          |

### 67.2.1 CLONEDB\_RENAMEFILE Procedure

This procedure is used to rename datafiles that were pointing to the backup set to the actual file name in cloned database.

The `srcfile` is the file name that represents the data file in the backup image copy or a read-only storage snapshot. The `destfile` destination file path must point to a NFS volume where cloneDB datafiles will be created. When the procedure is run successfully, the control file record is updated with the new datafile name.

### Syntax

```
DBMS_DNFS.CLONEDB_RENAMEFILE (  
    srcfile      IN      VARCHAR2,  
    destfile     IN      VARCHAR2);
```

### Parameters

**Table 67-2** *CLONEDB\_RENAMEFILE Procedure Parameters*

| Parameter | Description                              |
|-----------|------------------------------------------|
| srcfile   | Source datafile name in the control file |
| destfile  | New datafile name                        |

## 67.2.2 RESTORE\_DATAFILE\_PERMISSIONS Procedure

This procedure restores the file permissions for the data files belonging to the PDB to `read write`. PDB data files are converted to `read only` when one or more clones are created using this source PDB. This procedure must be invoked after the last clone is dropped to restore the data file permissions for the source PDB files.

### Syntax

```
DBMS_DNFS.RESTORE_DATAFILE_PERMISSIONS (  
    pdb_name     IN      VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 67-3** *RESTORE\_DATAFILE\_PERMISSIONS Procedure Parameters*

| Parameter | Description                                                            |
|-----------|------------------------------------------------------------------------|
| pdb_name  | Name of pluggable database whose file permissions need to be restored. |

## 67.2.3 UNMOUNTVOLUME Procedure

This procedure cleans up the cached Direct NFS file handles in SGA. This procedure must be used when any NFS mount changes are being made via the operating system and the OS unmount and mount commands are invoked.

The server is the host name or IP address of the NFS server. The volume is the exported path from the NFS server. This procedure will fail if the database has any open files in the volume that is being unmounted.

### Syntax

```
DBMS_DNFS.UNMOUNTVOLUME (  
    server      IN      VARCHAR2,  
    volume      IN      VARCHAR2);
```

## Parameters

**Table 67-4** *UNMOUNTVOLUME Procedure Parameters*

| Parameter | Description                         |
|-----------|-------------------------------------|
| server    | NFS server host name or IP address. |
| volume    | Exported path from the NFS server.  |

# DBMS\_DST

The DBMS\_DST package provides an interface to apply the Daylight Saving Time (DST) patch to the Timestamp with Time Zone datatype.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Views](#)
- [Summary of DBMS\\_DST Subprograms](#)

## See Also:

- *Oracle Database Globalization Support Guide*
- *Oracle Database Reference*

## 68.1 DBMS\_DST Overview

The transition period during which Daylight Saving Time comes into effect, or stops being in effect, has the potential for problems, such as data loss, when handling timestamps with time zone data. The DBMS\_DST package enables working with these transitions in the context of a set of rules.

## 68.2 DBMS\_DST Security Model

The DBMS\_DST package is an invoker's rights package.

## See Also:

*Oracle Database PL/SQL Language Reference* for more information about using Invoker Rights or Definer Rights

The execute privilege on the package is granted to the EXECUTE\_CATALOG\_ROLE role. This role is normally granted to selected users to allow EXECUTE privileges for packages and procedures in the data dictionary.

The user that invokes the package must have the following privileges:

- CREATE ANY TABLE
- ALTER ANY TABLE

- DROP ANY TABLE
- SELECT ANY TABLE
- LOCK ANY TABLE
- ALTER ANY INDEX
- ALTER ANY TRIGGER
- UPDATE ANY TABLE
- EXECUTE ANY TYPE

## 68.3 DBMS\_DST Views

The DBMS\_DST package uses views to display table information.

These views are shown in the following table. They are further described in the *Oracle Database Reference*:

**Table 68-1 Views used by DBMS\_DST**

| View             | Description                                                                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBA_TSTZ_TABLES  | Displays information about all tables in the database, which have columns defined on <code>TIMESTAMP WITH TIME ZONE</code> datatypes or object types containing attributes of <code>TIMESTAMP WITH TIME ZONE</code> datatypes. Its columns are the same as those in <code>ALL_TSTZ_TABLES</code>                                              |
| USER_TSTZ_TABLES | Displays information about the tables owned by the current user, which have columns defined on <code>TIMESTAMP WITH TIME ZONE</code> datatypes or object types containing attributes of <code>TIMESTAMP WITH TIME ZONE</code> datatypes. Its columns (except for <code>OWNER</code> ) are the same as those in <code>ALL_TSTZ_TABLES</code> . |
| ALL_TSTZ_TABLES  | Displays information about the tables accessible to the current user, which have columns defined on <code>TIMESTAMP WITH TIME ZONE</code> datatypes or object types containing attributes of <code>TIMESTAMP WITH TIME ZONE</code> datatypes                                                                                                  |

## 68.4 Summary of DBMS\_DST Subprograms

This table lists and describes the DBMS\_DST package subprograms.

**Table 68-2 DBMS\_DST Package Subprograms**

| Subprogram                                      | Description                                                                                                      |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <a href="#">BEGIN_PREPARE Procedure</a>         | Starts a prepare window                                                                                          |
| <a href="#">BEGIN_UPGRADE Procedure</a>         | Starts an upgrade window                                                                                         |
| <a href="#">CREATE_AFFECTED_TABLE Procedure</a> | Creates a table that has the schema shown in the comments for the <a href="#">FIND_AFFECTED_TABLES Procedure</a> |
| <a href="#">CREATE_ERROR_TABLE Procedure</a>    | Creates a log error table                                                                                        |

**Table 68-2 (Cont.) DBMS\_DST Package Subprograms**

| Subprogram                                     | Description                                                                                                                                                                       |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_TRIGGER_TABLE Procedure</a> | Creates a table that is used to record active triggers disabled before performing upgrade on the table, having not been enabled due to fatal failure during the upgrading process |
| <a href="#">END_PREPARE Procedure</a>          | Ends a prepare window                                                                                                                                                             |
| <a href="#">END_UPGRADE Procedure</a>          | Ends an upgrade window                                                                                                                                                            |
| <a href="#">FIND_AFFECTED_TABLES Procedure</a> | Finds all the tables that have affected TSTZ data due to the new timezone version                                                                                                 |
| <a href="#">UPGRADE_DATABASE Procedure</a>     | Upgrades all tables in the database that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type                                                    |
| <a href="#">UPGRADE_SCHEMA Procedure</a>       | Upgrades tables in a specified list of schemas that has one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type                                          |
| <a href="#">UPGRADE_TABLE Procedure</a>        | Upgrades a specified list of tables that has one or more columns defined on the TSTZ type or an ADT containing the TSTZ type                                                      |

## 68.4.1 BEGIN\_PREPARE Procedure

This procedure starts a prepare window. Once a prepare window is started successfully, the database property 'DST\_UPGRADE\_STATE' is set to 'PREPARE', and the database property 'SECONDARY\_TT\_VERSION' is set to a new timezone version.

The prepare window lets a DBA investigate data affected by the upgrade, and so judge when it is optimal to perform the upgrade. The prepare window can overlap normal database operation.

### Syntax

```
DBMS_DST.BEGIN_PREPARE (  
    new_version                IN BINARY_INTEGER);
```

### Parameters

**Table 68-3 BEGIN\_PREPARE Procedure Parameters**

| Parameter                | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <code>new_version</code> | New timezone version to which the database is to be prepared to upgrade |

## 68.4.2 BEGIN\_UPGRADE Procedure

This procedure starts an upgrade window.

When an upgraded window is started successfully, the TSTZ data in the dictionary tables is upgraded to reflect the new timezone version, and the database property 'DST\_UPGRADE\_STATE' is set to 'UPGRADE'. Once `BEGIN_UPGRADE` has been performed successfully, the user must re-start the database. After a successful restart, the database property 'PRIMARY\_TT\_VERSION' is the new timezone version, and 'SECONDARY\_TT\_VERSION' is the old timezone version.

The procedure operates atomically, and upgrades all or none of the dictionary tables and the database properties. It must be called in the database in `OPEN MIGRATE` mode.

### Syntax

```
DBMS_DST.BEGIN_UPGRADE (  
    new_version          IN  BINARY_INTEGER,  
    error_on_overlap_time IN  BOOLEAN := FALSE,  
    error_on_nonexisting_time IN BOOLEAN := FALSE);
```

### Parameters

**Table 68-4 BEGIN\_UPGRADE Procedure Parameters**

| Parameter                              | Description                                                                                                                                                                                                                          |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>new_version</code>               | New timezone version to which the database is to be upgraded                                                                                                                                                                         |
| <code>error_on_overlap_time</code>     | Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is <code>FALSE</code> . For more information about boundary cases, see <i>Oracle Database SQL Language Reference</i> . |
| <code>error_on_nonexisting_time</code> | Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default value is <code>FALSE</code> .                                                                                     |

## 68.4.3 CREATE\_AFFECTED\_TABLE Procedure

This procedure creates a table that has the schema shown in the comments for the `FIND_AFFECTED_TABLES` Procedure.

### Syntax

```
DBMS_DST.CREATE_AFFECTED_TABLE (  
    table_name          IN  VARCHAR2);
```

### Parameters

**Table 68-5 CREATE\_AFFECTED\_TABLE Procedure Parameters**

| Parameter               | Description               |
|-------------------------|---------------------------|
| <code>table_name</code> | Name of the table created |

### Usage Notes

This procedure takes a `table_name` without schema qualification, creating a table within the current user schema.

### Related Topics

- [FIND\\_AFFECTED\\_TABLES Procedure](#)  
This procedure finds all the tables which have affected TSTZ data due to the new timezone version.

## 68.4.4 CREATE\_ERROR\_TABLE Procedure

This procedure creates a log error table.

The table has the following schema:

```
CREATE TABLE dst$error_table(  
    table_owner    VARCHAR2(30),  
    table_name     VARCHAR2(30),  
    column_name    VARCHAR2(4000),  
    rid            ROWID,  
    error_number   NUMBER)
```

### Syntax

```
DBMS_DST.CREATE_ERROR_TABLE (  
    table_name      IN  VARCHAR2);
```

### Parameters

**Table 68-6 CREATE\_ERROR\_TABLE Procedure Parameters**

| Parameter  | Description               |
|------------|---------------------------|
| table_name | Name of the table created |

### Usage Notes

- This procedure takes a `table_name` without schema qualification, creating a table within the current user schema.
- The error number is found when upgrading time zone file and timestamp with time zone data. For more information about error handling when upgrading time zone file and timestamp with time zone data, see Oracle Database Globalization Support Guide

## 68.4.5 CREATE\_TRIGGER\_TABLE Procedure

This procedure creates a table to record active triggers that are disabled before performing upgrade on the table, having not been enabled due to fatal failure during the upgrading process.

The table has the following schema.

```
CREATE TABLE dst_trigger_table (  
    trigger_owner  VARCHAR2(30),  
    trigger_name   VARCHAR2(30));
```

### Syntax

```
DBMS_DST.CREATE_TRIGGER_TABLE (  
    table_name      IN  VARCHAR2);
```

## Parameters

**Table 68-7 CREATE\_TRIGGER\_TABLE Procedure Parameters**

| Parameter  | Description                 |
|------------|-----------------------------|
| table_name | Name of table to be created |

## Usage Notes

This procedure takes a `table_name` without schema qualification, creating a table within the current user schema.

## 68.4.6 END\_PREPARE Procedure

This procedure ends a prepare window.

### Syntax

```
DBMS_DST.END_PREPARE;
```

## 68.4.7 END\_UPGRADE Procedure

This procedure ends an upgrade window. An upgraded window is ended if all the affected user tables have been upgraded. Otherwise, the OUT parameter `num_of_failures` indicates how many tables have not been converted.

### Syntax

```
DBMS_DST.END_UPGRADE (  
    num_of_failures    OUT    BINARY_INTEGER);
```

## Parameters

**Table 68-8 END\_UPGRADE Procedure Parameters**

| Parameter       | Description                            |
|-----------------|----------------------------------------|
| num_of_failures | Number of tables that fail to complete |

## 68.4.8 FIND\_AFFECTED\_TABLES Procedure

This procedure finds all the tables which have affected TSTZ data due to the new timezone version.

This procedure can only be invoked during a prepare window. The tables which have affected TSTZ data are recorded into a table indicated by parameter `affected_tables`. If semantic errors must be logged, they are recorded into a table indicated by parameter `log_errors_table`.

### Syntax

```
DBMS_DST.FIND_AFFECTED_TABLES (  
    affected_tables    IN    VARCHAR2 := 'sys.dst$affected_tables',  
    log_errors         IN    BOOLEAN := FALSE,
```

```
log_errors_table      IN  VARCHAR2 := 'sys.dst$error_table',
parallel              IN  BOOLEAN := FALSE;
```

**Parameters**

**Table 68-9 FIND\_AFFECTED\_TABLES Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| affected_tables  | <p>Name of table with the following schema:</p> <pre>CREATE TABLE dst\$affected_tables (   table_owner VARCHAR2(30),   table_name VARCHAR2(30),   column_name VARCHAR2(4000),   row_count NUMBER,   error_count NUMBER)</pre> <p>The table can be created with the <a href="#">CREATE_AFFECTED_TABLE Procedure</a>.</p>                                                                                                              |
| log_errors       | <p>Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table.</p> <p>The default is FALSE.</p>                                                                                                                                                                       |
| log_errors_table | <p>Table name with the following schema:</p> <pre>CREATE TABLE dst\$error_table (   table_owner VARCHAR2(30),   table_name VARCHAR2(30),   column_name VARCHAR2(4000),   rid ROWID,   error_number NUMBER)</pre> <p>The table can be created with the <a href="#">CREATE_ERROR_TABLE Procedure</a>. The rid column records the rowids of the offending rows, and the error_number column records the corresponding error number.</p> |
| parallel         | <p>Boolean flag indicating whether to find the affected tables using parallel queries or serial queries. The default is FALSE.</p>                                                                                                                                                                                                                                                                                                   |

**68.4.9 UPGRADE\_DATABASE Procedure**

This procedure upgrades all tables in the database, which have one or more columns defined on the TSTZ type or an ADT containing the TSTZ type.

This procedure can only be invoked after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that, a base table and its materialized view log table are upgraded in an atomic transaction.

**Syntax**

```
DBMS_DST.UPGRADE_DATABASE (
  num_of_failures      OUT BINARY_INTEGER,
  upgrade_data          IN  BOOLEAN := TRUE,

## Parameters

**Table 68-10 UPGRADE\_DATABASE Procedure Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num_of_failures           | Number of tables that fail to complete                                                                                                                                                                                                                                                                                                                                                                                     |
| upgrade_data              | Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave it unconverted (FALSE).The default is TRUE.                                                                                                                                                                                                                                                                    |
| parallel                  | Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML.The default is FALSE.                                                                                                                                                                                                                                                                                                            |
| continue_after_errors     | Boolean flag indicating whether to continue after upgrade fails on the current table.<br>The default is TRUE.                                                                                                                                                                                                                                                                                                              |
| log_errors                | Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, errors are logged to the log_errors_table.<br>The default is FALSE.                                                                                                                                                                          |
| log_errors_table          | Table name with the following schema:<br><br><pre>CREATE TABLE dst\$error_table ( table_owner VARCHAR2(30), table_name VARCHAR2(30), column_name VARCHAR2(4000), rid ROWID, error_number NUMBER)</pre> <p>The table can be created with the <a href="#">CREATE_ERROR_TABLE Procedure</a>. The rid column records the rowids of the offending rows, and the error_number column records the corresponding error number.</p> |
| error_on_overlap_time     | Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error.<br>The default is TRUE.                                                                                                                                                                                                                                                                                                  |
| error_on_nonexisting_time | Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error.<br>The default is TRUE.                                                                                                                                                                                                                                                                                             |
| log_triggers_table        | Table to log triggers which are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade                                                                                                                                                                                                                                                                                         |

## 68.4.10 UPGRADE\_SCHEMA Procedure

This procedure upgrades tables in a specified list of schemas that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type.

This procedure can be invoked only after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that a base table and its materialized view log table are upgraded in an atomic transaction.

### Syntax

```
DBMS_DST.UPGRADE_SCHEMA (
    num_of_failures      OUT BINARY_INTEGER,
    schema_list          IN  VARCHAR2,
    upgrade_data         IN  BOOLEAN := TRUE,
    parallel             IN  BOOLEAN := FALSE,
    continue_after_errors IN  BOOLEAN := TRUE,
    log_errors           IN  BOOLEAN := FALSE,
    log_errors_table     IN  VARCHAR2 := 'sys.dst$error_table' ,
    error_on_overlap_time IN  BOOLEAN := FALSE,
    error_on_nonexisting_time IN  BOOLEAN := FALSE,
    log_triggers_table   IN  VARCHAR2 := 'sys.dst$trigger_table');
```

### Parameters

**Table 68-11 UPGRADE\_SCHEMA Procedure Parameters**

| Parameter             | Description                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num_of_failures       | Number of tables that fail to complete                                                                                                                                                                                                              |
| schema_list           | Schema name list (comma separated strings)                                                                                                                                                                                                          |
| upgrade_data          | Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE) or to leave unconverted (FALSE). The default is TRUE.                                                                                                |
| parallel              | Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML. The default is FALSE.                                                                                                                                    |
| continue_after_errors | Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.                                                                                                                                          |
| log_errors            | Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table.<br>The default is FALSE. |

## 68.4.11 UPGRADE\_TABLE Procedure

This procedure upgrades a specified list of tables that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type.

### Syntax

```
DBMS_DST.UPGRADE_TABLE (
  num_of_failures      OUT BINARY_INTEGER,
  table_list           IN  VARCHAR2,
  upgrade_data         IN  BOOLEAN := TRUE,
  parallel             IN  BOOLEAN := FALSE,
  continue_after_errors IN  BOOLEAN := TRUE,
  log_errors           IN  BOOLEAN := FALSE,
  log_errors_table     IN  VARCHAR2 := 'sys.dst$error_table' ,
  error_on_overlap_time IN  BOOLEAN := FALSE,
  error_on_nonexisting_time IN  BOOLEAN := FALSE,
  log_triggers_table   IN  VARCHAR2 := 'sys.dst$trigger_table',
  atomic_upgrade       IN  BOOLEAN := FALSE);
```

### Parameters

| upgrade_data              | Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave unconverted (FALSE).<br>The default is TRUE.                                                                                                                                                                                                                                            |
| parallel                  | Boolean flag indicating whether to convert tables using PDML (Parallel DML), or Serial DML.<br>The default is FALSE.                                                                                                                                                                                                                                                                                |
| continue_after_errors     | Boolean flag indicating whether to continue after upgrade fails on the current table.<br>The default is TRUE.                                                                                                                                                                                                                                                                                       |
| log_errors                | Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table.<br>The default is FALSE.                                                                                                                                                 |
| log_errors_table          | Table name with the following schema:<br><br><pre>CREATE TABLE dst\$error_table (   table_owner VARCHAR2(30),   table_name VARCHAR2(30),   column_name VARCHAR2(4000),   rid ROWID,   error_number NUMBER)</pre><br>The table can be created with the <a href="#">CREATE_ERROR_TABLE Procedure</a> . The rid parameter records the rowids of the offending rows and the corresponding error number. |
| error_on_overlap_time     | Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error.<br>The default is TRUE.                                                                                                                                                                                                                                                                           |
| error_on_nonexisting_time | Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error.<br>The default is TRUE.                                                                                                                                                                                                                                                                      |
| log_triggers_table        | Table to log triggers that are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade                                                                                                                                                                                                                                                                   |
| atomic_upgrade            | Boolean flag indicating whether to convert the listed tables atomically (in a single transaction). If FALSE, each table is converted in its own transaction.<br>The default is FALSE.                                                                                                                                                                                                               |

### Usage Notes

This procedure can only be invoked after an upgrade window has been started. The table list has to satisfy the following partial ordering:

1. If a base table has a materialized view log table, the log table must be the next item in the list.
2. If the container table for a materialized view appears in the list, the materialized view's 'non-upgraded' base tables and log tables must appear in the table list and before the container table.

A base table and its materialized view log table need to be upgraded in an atomic transaction by specifying `atomic_upgrade` to `TRUE`.

# DBMS\_EDITIONS\_UTILITIES

The `DBMS_EDITIONS_UTILITIES` package provides helper functions for edition-related operations.

The chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Exceptions](#)
- [Summary of DBMS\\_EDITIONS\\_UTILITIES Subprograms](#)

## 69.1 DBMS\_EDITIONS\_UTILITIES Overview

The `DBMS_EDITIONS_UTILITIES` package implements an interface which provides helper functions for edition-related operations.

## 69.2 DBMS\_EDITIONS\_UTILITIES Security Model

This package is owned by `SYS` with execute access granted to `PUBLIC`. It runs with invoker's rights, that is, with the security profile of the caller.

## 69.3 DBMS\_EDITIONS\_UTILITIES Exceptions

The table in this topic lists exception messages created by `DBMS_EDITIONS_UTILITIES`.

**Table 69-1 DBMS\_EDITIONS\_UTILITIES Error Messages**

| Error     | Description             |
|-----------|-------------------------|
| ORA-38817 | Insufficient privileges |
| ORA-942   | Missing table           |

## 69.4 Summary of DBMS\_EDITIONS\_UTILITIES Subprograms

This table lists and describes the `DBMS_EDITIONS_UTILITIES` package subprograms.

**Table 69-2 DBMS\_EDITIONS\_UTILITIES Package Subprograms**

| Subprogram                                        | Description                                                                                |
|---------------------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">CLEAN_UNUSABLE_EDITIONS Procedure</a> | Drops covered objects in unusable editions, and drops empty unusable editions if possible. |

**Table 69-2 (Cont.) DBMS\_EDITIONS\_UTILITIES Package Subprograms**

| Subprogram                                               | Description                                                                                                                             |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SET_EDITIONING_VIEWS_READ_ONLY Procedure</a> | Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to READ ONLY or READ/WRITE |
| <a href="#">SET_NULL_COLUMN_VALUES_TO_EXPR Procedure</a> | For use only during an edition-based redefinition (EBR) exercise                                                                        |

## 69.4.1 CLEAN\_UNUSABLE\_EDITIONS Procedure

Drops all covered objects in any unusable editions and drops empty unusable editions.

The `CLEAN_UNUSABLE_EDITIONS` procedure executes immediately and in its entirety.

### Syntax

```
DBMS_EDITIONS_UTILITIES.CLEAN_UNUSABLE_EDITIONS ( );
```

### Usage Notes

The `COMPATIBLE` parameter must be set to 12.2.0 or higher for this procedure to execute.

#### See Also:

- *Oracle Database SQL Language Reference* for information about `DROP EDITION`
- *Oracle Database Development Guide* for more information about using edition-based redefinition

## 69.4.2 SET\_EDITIONING\_VIEWS\_READ\_ONLY Procedure

Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to READ ONLY or READ/WRITE.

### Syntax

```
DBMS_EDITIONS_UTILITIES.SET_EDITIONING_VIEWS_READ_ONLY (
    table_name IN VARCHAR2,
    owner      IN VARCHAR2 DEFAULT NULL,
    read_only  IN BOOLEAN  DEFAULT TRUE);
```

### Parameters

**Table 69-3 SET\_EDITIONING\_VIEWS\_READ\_ONLY Procedure Parameters**

| Parameter               | Description                                                                   |
|-------------------------|-------------------------------------------------------------------------------|
| <code>table_name</code> | Base table of the editioning views                                            |
| <code>owner</code>      | Base table schema. The default (or <code>NULL</code> ) is the current schema. |

**Table 69-3 (Cont.) SET\_EDITIONING\_VIEWS\_READ\_ONLY Procedure Parameters**

| Parameter | Description                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------|
| read_only | TRUE to set the views to read-only; FALSE (or NULL) sets the views to READ/WRITE. Default is TRUE. |

#### Usage Notes

The user must have the following privileges:

- Owner of the table, or have the ALTER ANY TABLE system privileges
- USE object privilege on all the editions for which the views are defined

### 69.4.3 SET\_NULL\_COLUMN\_VALUES\_TO\_EXPR Procedure

This procedure replaces NULL values in a replacement column with the value of an expression.

The expression evaluation cost is deferred to future updates and queries. The procedure is intended for use only during an edition-based redefinition (EBR) exercise.

#### See Also:

- *Oracle Database Development Guide* regarding transforming pre- to post-upgrade representation

#### Syntax

```
DBMS_EDITIONS_UTILITIES.SET_NULL_COLUMN_VALUES_TO_EXPR;
    table_name    IN  VARCHAR2,
    column_name   IN  VARCHAR2,
    expression     IN  VARCHAR2);
```

#### Parameters

**Table 69-4 SET\_NULL\_COLUMN\_VALUES\_TO\_EXPR Procedure Parameters**

| Parameter   | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| table_name  | A potentially schema-qualified table name                                         |
| column_name | Name of the column to be updated                                                  |
| expression  | An expression composed of columns in the same table, constants, and SQL functions |

## DBMS\_EPG

The `DBMS_EPG` package implements the embedded PL/SQL gateway that enables a Web browser to invoke a PL/SQL stored procedure through an HTTP listener.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Exceptions](#)
- [Data Structures](#)
  - [VARCHAR2\\_TABLE Table Type](#)
- [Subprogram Groups](#)
- [Summary of DBMS\\_EPG Subprograms](#)

### 70.1 DBMS\_EPG Overview

The `DBMS_EPG` package is a platform on which PL/SQL users develop and deploy PL/SQL Web applications. The embedded PL/SQL gateway is an embedded version of the gateway that runs in the XML database HTTP server in the Oracle database. It provides the core features of `mod_plsql` in the database but does not require the Oracle HTTP server powered by Apache.

In order to make a PL/SQL application accessible from a browser by way of HTTP, a Database Access Descriptor (DAD) must be created and mapped to a virtual path. A DAD is a set of configuration values used for database access and the virtual path mapping makes the application accessible under a virtual path of the XML DB HTTP Server. A DAD is represented as a servlet in XML DB HTTP Server.

### 70.2 DBMS\_EPG Security Model

The `XDBADMIN` role is required to invoke the configuration interface. It may be invoked by the database user "XDB".

The authorization interface can be invoked by any user.

### 70.3 DBMS\_EPG Exceptions

The table in this topic lists the exceptions raised by the `DBMS_EPG` package.

**Table 70-1 DBMS\_EPG Exceptions**

| Exception     | Error Code | Description                                                                                                   |
|---------------|------------|---------------------------------------------------------------------------------------------------------------|
| DAD_NOT_FOUND | 20000      | Database Access Descriptor (DAD) %s not found. Ensure that the name of the DAD is correct and that it exists. |

## 70.4 DBMS\_EPG Data Structures

The DBMS\_EPG package defines a TABLE type.

### VARCHAR2\_TABLE Table Type

This type is used by the procedures GET\_ALL\_GLOBAL\_ATTRIBUTES, GET\_ALL\_DAD\_ATTRIBUTES, GET\_ALL\_DAD\_MAPPINGS, and GET\_DAD\_LIST to return lists of attribute names, attribute values, virtual paths, and database access descriptors (DAD).

```
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(4000) INDEX BY BINARY_INTEGER;
```

## 70.5 DBMS\_EPG Subprogram Groups

The DBMS\_EPG consists of two interfaces: configuration subprograms and authorization subprograms.

- [Configuration Subprograms](#)
- [Authorization Subprograms](#)

### 70.5.1 DBMS\_EPG Configuration Subprograms

The Configuration subprogram group contain the subprogram interfaces to examine and modify the global and database access descriptor (DAD) specific settings of the embedded PL/SQL gateway.

**Table 70-2 Configuration Subprogram Group**

| Subprogram                                          | Description                                                       |
|-----------------------------------------------------|-------------------------------------------------------------------|
| <a href="#">CREATE_DAD Procedure</a>                | Creates a new DAD                                                 |
| <a href="#">DELETE_DAD_ATTRIBUTE Procedure</a>      | Deletes a DAD attribute                                           |
| <a href="#">DELETE_GLOBAL_ATTRIBUTE Procedure</a>   | Deletes a global attribute                                        |
| <a href="#">DROP_DAD Procedure</a>                  | Drops a DAD                                                       |
| <a href="#">GET_ALL_DAD_ATTRIBUTES Procedure</a>    | Retrieves all the attributes of a DAD.                            |
| <a href="#">GET_ALL_DAD_MAPPINGS Procedure</a>      | Retrieves all virtual paths to which the specified DAD is mapped. |
| <a href="#">GET_ALL_GLOBAL_ATTRIBUTES Procedure</a> | Retrieves all global attributes and values                        |
| <a href="#">GET_DAD_ATTRIBUTE Function</a>          | Retrieves the value of a DAD attribute                            |
| <a href="#">GET_DAD_LIST Procedure</a>              | Retrieves a list of all DADs for an Embedded Gateway instance.    |
| <a href="#">GET_GLOBAL_ATTRIBUTE Function</a>       | Retrieves the value of a global attribute                         |
| <a href="#">MAP_DAD Procedure</a>                   | Maps a DAD to the specified virtual path.                         |
| <a href="#">SET_DAD_ATTRIBUTE Procedure</a>         | Sets the value for a DAD                                          |
| <a href="#">SET_GLOBAL_ATTRIBUTE Procedure</a>      | Sets the value of a global attribute                              |
| <a href="#">UNMAP_DAD Procedure</a>                 | Unmaps a DAD from the specified virtual path                      |

## 70.5.2 DBMS\_EPG Authorization Subprograms

The Authorization subprogram group contains the subprogram interfaces to authorize and deauthorize the use of a database user's privileges by the embedded PL/SQL gateway through a specific database access descriptor (DAD)

**Table 70-3 Authorization Subprogram Group**

| Subprogram                                | Description                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">AUTHORIZE_DAD Procedure</a>   | Authorizes a DAD to invoke procedures and access document tables with a database user's privileges                    |
| <a href="#">DEAUTHORIZE_DAD Procedure</a> | Deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges |

## 70.6 Summary of DBMS\_EPG Subprograms

This table lists the DBMS\_ALERT subprograms and briefly describes them.

**Table 70-4 DBMS\_EPG Package Subprograms**

| Subprogram                                          | Description                                                                                                           |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">AUTHORIZE_DAD Procedure</a>             | authorizes a DAD to invoke procedures and access document tables with a database user's privileges                    |
| <a href="#">CREATE_DAD Procedure</a>                | Creates a new DAD                                                                                                     |
| <a href="#">DEAUTHORIZE_DAD Procedure</a>           | Deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges |
| <a href="#">DELETE_DAD_ATTRIBUTE Procedure</a>      | Deletes a DAD attribute                                                                                               |
| <a href="#">DELETE_GLOBAL_ATTRIBUTE Procedure</a>   | Deletes a global attribute                                                                                            |
| <a href="#">DROP_DAD Procedure</a>                  | Drops a DAD                                                                                                           |
| <a href="#">GET_ALL_DAD_ATTRIBUTES Procedure</a>    | Retrieves all the attributes of a DAD.                                                                                |
| <a href="#">GET_ALL_DAD_MAPPINGS Procedure</a>      | Retrieves all virtual paths to which the specified DAD is mapped.                                                     |
| <a href="#">GET_ALL_GLOBAL_ATTRIBUTES Procedure</a> | Retrieves all global attributes and values                                                                            |
| <a href="#">GET_DAD_ATTRIBUTE Function</a>          | Retrieves the value of a DAD attribute                                                                                |
| <a href="#">GET_DAD_LIST Procedure</a>              | Retrieves a list of all DADs for an Embedded Gateway instance.                                                        |
| <a href="#">GET_GLOBAL_ATTRIBUTE Function</a>       | Retrieves the value of a global attribute                                                                             |

| <a href="#">SET_GLOBAL_ATTRIBUTE Procedure</a>      | Sets the value of a global attribute                                                                                  |
| <a href="#">UNMAP_DAD Procedure</a>                 | Unmaps a DAD from the specified virtual path                                                                          |

## 70.6.1 AUTHORIZE\_DAD Procedure

This procedure authorizes a DAD to invoke procedures and access document tables with a database user's privileges. The invoker can always authorize the use of her/his own privileges.

### See Also:

[Authorization Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.AUTHORIZE_DAD (  
    dad_name  IN  VARCHAR2,  
    path      IN  VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 70-5 AUTHORIZE\_DAD Procedure Parameters**

| Parameter | Description                                                               |
|-----------|---------------------------------------------------------------------------|
| dad_name  | The name of the DAD to create                                             |
| user      | The user whose privileges to deauthorize. If use, the invoker is assumed. |

### Usage Notes

- To authorize the use of another user's privileges, the invoker must have the `ALTER USER` system privilege.
- The DAD must exist but its "database-username" DAD attribute does not have to be set to user to authorize.
- Multiple users can authorize the same DAD and it is up to the DAD's "database-username" setting to decide which user's privileges to use.

### Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

### Examples

```
DBMS_EPG.AUTHORIZE_DAD('HR');
```

## 70.6.2 CREATE\_DAD Procedure

This procedure creates a new DAD.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.CREATE_DAD (  
    dad_name  IN  VARCHAR2,  
    path      IN  VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 70-6 CREATE\_DAD Procedure Parameters**

| Parameter | Description                              |
|-----------|------------------------------------------|
| dad_name  | The name of the DAD to create            |
| path      | The virtual path to which to map the DAD |

## 70.6.3 DEAUTHORIZE\_DAD Procedure

This procedure deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges. The invoker can always deauthorize the use of his own privileges.

### See Also:

[Authorization Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.DEAUTHORIZE_DAD (  
    dad_name  IN  VARCHAR2,  
    path      IN  VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 70-7 DEAUTHORIZE\_DAD Procedure Parameters**

| Parameter | Description                                                               |
|-----------|---------------------------------------------------------------------------|
| dad_name  | The name of the DAD for which to deauthorize use                          |
| user      | The user whose privileges to deauthorize. If use, the invoker is assumed. |

### Usage Notes

To deauthorize the use of another user's privileges, the invoker must have the `ALTER USER` system privilege.

### Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

### Examples

```
DBMS_EPG.DEAUTHORIZE_DAD('HR');
```

## 70.6.4 DELETE\_DAD\_ATTRIBUTE Procedure

This procedure deletes a DAD attribute.

#### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.DELETE_DAD_ATTRIBUTE (
    dad_name      IN  VARCHAR2,
    attr_name     IN  VARCHAR2);
```

### Parameters

**Table 70-8 DELETE\_DAD\_ATTRIBUTE Procedure Parameters**

| Parameter              | Description                                             |
|------------------------|---------------------------------------------------------|
| <code>dad_name</code>  | The name of the DAD for which to delete a DAD attribute |
| <code>attr_name</code> | The name of the DAD attribute to delete                 |

### Exceptions

Raises an error if DAD does not exist

## 70.6.5 DELETE\_GLOBAL\_ATTRIBUTE Procedure

This procedure deletes a global attribute.

#### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.DELETE_GLOBAL_ATTRIBUTE (  
    attr_name      IN  VARCHAR2);
```

### Parameters

**Table 70-9 DELETE\_GLOBAL\_ATTRIBUTE Procedure Parameters**

| Parameter | Description                    |
|-----------|--------------------------------|
| attr_name | The global attribute to delete |

## 70.6.6 DROP\_DAD Procedure

This procedure drops a DAD. All the virtual-path mappings of the DAD will be dropped also.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.DROP_DAD (  
    dadname  IN  VARCHAR2);
```

### Parameters

**Table 70-10 DROP\_DAD Procedure Parameters**

| Parameter | Description     |
|-----------|-----------------|
| dad_name  | The DAD to drop |

### Exceptions

Raises an error if the DAD does not exist.

## 70.6.7 GET\_ALL\_DAD\_ATTRIBUTES Procedure

This procedure retrieves all the attributes of a DAD. The outputs are 2 correlated index-by tables of the name/value pairs.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

## Syntax

```
DBMS_EPG.GET_ALL_DAD_ATTRIBUTES (
    dad_name      IN          VARCHAR2,
    attr_names    OUT NOCOPY  VARCHAR2_TABLE,
    attr_values   OUT NOCOPY  VARCHAR2_TABLE);
```

## Parameters

**Table 70-11 GET\_ALL\_DAD\_ATTRIBUTES Procedure Parameters**

| Parameter   | Description          |
|-------------|----------------------|
| dad_names   | The name of the DAD  |
| attr_names  | The attribute names  |
| attr_values | The attribute values |

## Exceptions

Raises an error if DAD does not exist.

## Usage Notes

If the DAD has no attributes set, then `attr_names` and `attr_values` will be set to empty arrays.

# 70.6.8 GET\_ALL\_DAD\_MAPPINGS Procedure

This procedure retrieves all the virtual paths to which the specified DAD is mapped.

## See Also:

[Configuration Subprograms](#) for other subprograms in this group

## Syntax

```
DBMS_EPG.GET_ALL_DAD_MAPPINGS (
    dad_name      IN          VARCHAR2,
    paths         OUT NOCOPY  VARCHAR2_TABLE);
```

## Parameters

**Table 70-12 GET\_ALL\_DAD\_MAPPINGS Procedure Parameters**

| Parameter | Description                                    |
|-----------|------------------------------------------------|
| dad_names | The name of the DAD                            |
| paths     | The virtual paths to which h the DAD is mapped |

## Exceptions

Raises an error if DAD does not exist.

### Usage Notes

If the DAD is not mapped to any virtual path, `paths` will be set to empty arrays.

## 70.6.9 GET\_ALL\_GLOBAL\_ATTRIBUTES Procedure

This procedure retrieves all global attributes and values. The outputs are 2 correlated index-by-tables of the name/value pairs.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.GET_ALL_GLOBAL_ATTRIBUTES (
    attr_names      OUT  NOCOPY  VARCHAR2_TABLE,
    attr_values     OUT  NOCOPY  VARCHAR2_TABLE);
```

### Parameters

**Table 70-13 GET\_ALL\_GLOBAL\_ATTRIBUTES Procedure Parameters**

| Parameter                | Description                         |
|--------------------------|-------------------------------------|
| <code>attr_names</code>  | The global attribute names          |
| <code>attr_values</code> | The values of the global attributes |

### Usage Notes

If the gateway instance has no global attributes set, then `attr_names` and `attr_values` will be set to empty arrays.

## 70.6.10 GET\_DAD\_ATTRIBUTE Function

This procedure retrieves the value of a DAD attribute.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.GET_DAD_ATTRIBUTE (
    dad_name      IN  VARCHAR2,
    attr_name     IN  VARCHAR2)
RETURN VARCHAR2;
```

## Parameters

**Table 70-14 GET\_DAD\_ATTRIBUTE Function Parameters**

| Parameter | Description                                          |
|-----------|------------------------------------------------------|
| dad_name  | The name of the DAD for which to delete an attribute |
| attr_name | The name of the attribute to delete                  |

## Return values

Returns the DAD attribute value. Returns `NULL` if attribute is unknown or has not been set.

## Exceptions

Raises an error if DAD does not exist.

## 70.6.11 GET\_DAD\_LIST Procedure

This procedure retrieves a list of all DADs for an Embedded Gateway instance.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

## Syntax

```
DBMS_EPG.GET_DAD_LIST (
    dad_names      OUT NOCOPY  VARCHAR2_TABLE);
```

## Parameters

**Table 70-15 GET\_DAD\_LIST Procedure Parameters**

| Parameter | Description          |
|-----------|----------------------|
| dad_names | The list of all DADs |

## Usage Notes

If no DADs exist then `dad_names` will be set to an empty array.

## 70.6.12 GET\_GLOBAL\_ATTRIBUTE Function

This function retrieves the value of a global attribute.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.GET_GLOBAL_ATTRIBUTE (  
    attr_name IN VARCHAR2)  
RETURN VARCHAR2;
```

### Parameters

**Table 70-16 GET\_GLOBAL\_ATTRIBUTE Procedure Parameters**

| Parameter | Description                      |
|-----------|----------------------------------|
| attr_name | The global attribute to retrieve |

### Return Values

Returns the global attribute value. Returns `NULL` if attribute has not been set or is not a valid attribute.

## 70.6.13 MAP\_DAD Procedure

This procedure maps a DAD to the specified virtual path. If the virtual path exists already, the old virtual-path mapping will be overridden.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.MAP_DAD (  
    dad_name IN VARCHAR2,  
    path     IN VARCHAR2);
```

### Parameters

**Table 70-17 MAP\_DAD Procedure Parameters**

| Parameter | Description                |
|-----------|----------------------------|
| dad_name  | The name of the DAD to map |
| path      | The virtual path to map    |

### Exceptions

Raises an error if the DAD does not exist.

## 70.6.14 SET\_DAD\_ATTRIBUTE Procedure

This procedure sets the value for a DAD.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.SET_DAD_ATTRIBUTE (
    dad_name     IN  VARCHAR2,
    attr_name    IN  VARCHAR2,  attr_value IN  VARCHAR2);
```

### Parameters

**Table 70-18 SET\_DAD\_ATTRIBUTE Procedure Parameters**

| Parameter  | Description                                        |
|------------|----------------------------------------------------|
| dad_name   | The name of the DAD for which to set the attribute |
| attr_name  | The name of the attribute to set                   |
| attr_value | The attribute value to set                         |

**Table 70-19 Mapping Between mod\_plsql and Embedded PL/SQL Gateway DAD Attributes**

| mod_plsql DAD Attribute       | Embedded PL/SQL Gateway DAD Attribute | Allows Multiple Occurrences | Legal Values                                                            |
|-------------------------------|---------------------------------------|-----------------------------|-------------------------------------------------------------------------|
| PlsqlAfterProcedure           | after-procedure                       | No                          | String                                                                  |
| PlsqlAlwaysDescribe Procedure | always-describe-procedure             | No                          | Enumeration of On, Off                                                  |
| PlsqlAuthentication Mode      | authentication-mode                   | No                          | Enumeration of Basic, SingleSignOn, GlobalOwa, CustomOwa, PerPackageOwa |

| PlsqlSessionStateManagement    | session-state-management                     | No                                 | Enumeration of StatelessWithResetPackageState, StatelessWithFastRestPackageState, StatelessWithPreservePackageState |
| PlsqlTransferMode              | transfer-mode                                | No                                 | Enumeration of Char, Raw                                                                                            |
| PlsqlUploadAsLongRaw           | upload-as-long-raw                           | No                                 | String                                                                                                              |

### Exceptions

Raises an error if DAD does not exist or the attribute is unknown.

### Usage Notes

- If `attr_name` attribute has been set before, then the old value will be overwritten with the new `attr_value` argument.

- The embedded gateway assumes default values when the attributes are not set. The default values of the DAD attributes should be sufficient for most users of the embedded gateway. `mod_plsql` users should note the following
  - The `PlsqlDatabasePassword` attribute is not needed.
  - The `PlsqlDatabaseConnectString` attribute is not needed because the embedded gateway does not support logon to external databases.

### Examples

```
DBMS_EPG.SET_DAD_ATTRIBUTE('HR', 'default-page', 'HRApp.home');
```

## 70.6.15 SET\_GLOBAL\_ATTRIBUTE Procedure

This procedure sets the value of a global attribute.

### See Also:

[Configuration Subprograms](#) for other subprograms in this group

### Syntax

```
DBMS_EPG.SET_GLOBAL_ATTRIBUTE (
    attr_name      IN VARCHAR2,
    attr_value     IN VARCHAR2);
```

### Parameters

**Table 70-20 SET\_GLOBAL\_ATTRIBUTE Procedure Parameters**

| Parameter               | Description                 |
|-------------------------|-----------------------------|
| <code>attr_name</code>  | The global attribute to set |
| <code>attr_value</code> | The attribute value to set  |

**Table 70-21 Mapping Between `mod_plsql` and Embedded PL/SQL Gateway Global Attributes**

| <code>mod_plsql</code> Global Attribute | Embedded PL/SQL Gateway Global Attribute | Allows Multiple Occurrences | Legal Values     |
|-----------------------------------------|------------------------------------------|-----------------------------|------------------|
| <code>PlsqlLogLevel</code>              | <code>log-level</code>                   | No                          | Unsigned integer |
| <code>PlsqlMaxParameters</code>         | <code>max-parameters</code>              | No                          | Unsigned integer |

### Usage Notes

- The attribute name is case sensitive. The value may or may not be case-sensitive depending on the attribute.
- If `attr_name` attribute has been set before, then the old value will be overwritten with the new `attr_value` argument.

Exceptions

Raises an error if the attribute is unknown.

Examples

```
dbms_epg.set_global_attribute('max-parameters', '100');
```

70.6.16 UNMAP\_DAD Procedure

This procedure unmaps a DAD from the specified virtual path. If path is `NULL`, the procedure removes all virtual-path mappings for the DAD but keeps the DAD.

 **See Also:**

[Configuration Subprograms](#) for other subprograms in this group

Syntax

```
DBMS_EPG.UNMAP_DAD (
    dad_name IN VARCHAR2,
    path      IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 70-22 UNMAP\_DAD Procedure Parameters

| Parameter | Description                  |
|-----------|------------------------------|
| dad_name  | The name of the DAD to unmap |
| path      | The virtual path to unmap    |

Usage Notes

Raises and error if the DAD does not exist.

# DBMS\_ERRLOG

The `DBMS_ERRLOG` package provides a procedure that enables you to create an error logging table so that DML operations can continue after encountering errors rather than abort and roll back. This enables you to save time and system resources.

This chapter contains the following topics:

- [Security Model](#)
- [Summary of DBMS\\_ERRLOG Subprograms](#)

## See Also:

*Oracle Database Data Warehousing Guide* for more information regarding how to use `DBMS_ERRLOG` and *Oracle Database SQL Language Reference* for `error_logging_clause` syntax

## 71.1 DBMS\_ERRLOG Security Model

Security on this package can be controlled by granting `EXECUTE` on this package to selected users or roles. The `EXECUTE` privilege is granted publicly. However, to create an error logging table, you need `SELECT` access on the base table or view, the `CREATE TABLE` privilege, as well as tablespace quota for the target tablespace.

## 71.2 Summary of DBMS\_ERRLOG Subprograms

The `DBMS_ERRORLOG` package includes the `CREATE_ERROR_LOG` procedure subprogram.

**Table 71-1 DBMS\_ERRLOG Package Subprograms**

| Subprogram                                 | Description                                               |
|--------------------------------------------|-----------------------------------------------------------|
| <a href="#">CREATE_ERROR_LOG Procedure</a> | Creates the error logging table used in DML error logging |

### 71.2.1 CREATE\_ERROR\_LOG Procedure

This procedure creates the error logging table needed to use the DML error logging capability.

`LONG`, `CLOB`, `BLOB`, `BFILE`, and `ADT` datatypes are not supported in the columns.

#### Syntax

```
DBMS_ERRLOG.CREATE_ERROR_LOG (
    dml_table_name      IN VARCHAR2,
    err_log_table_name  IN VARCHAR2 := NULL,
```

```
err_log_table_owner      IN VARCHAR2 := NULL,  
err_log_table_space      IN VARCHAR2 := NULL,  
skip_unsupported         IN BOOLEAN := FALSE);
```

Parameters

Table 71-2 CREATE\_ERROR\_LOG Procedure Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dml_table_name      | The name of the DML table to base the error logging table on. The name can be fully qualified (for example, emp, scott.emp, "EMP", "SCOTT"."EMP"). If a name component is enclosed in double quotes, it will not be upper cased.                                                                       |
| err_log_table_name  | The name of the error logging table you will create.<br>The default is the first 25 characters in the name of the DML table prefixed with 'ERR\$'. Examples are the following:<br>dml_table_name: 'EMP', err_log_table_name: 'ERR\$_EMP'<br>dml_table_name: '"Emp2"', err_log_table_name: 'ERR\$_Emp2' |
| err_log_table_owner | The name of the owner of the error logging table. You can specify the owner in dml_table_name. Otherwise, the schema of the current connected user is used.                                                                                                                                            |
| err_log_table_space | The tablespace the error logging table will be created in. If not specified, the default tablespace for the user owning the DML error logging table will be used.                                                                                                                                      |
| skip_unsupported    | When set to TRUE, column types that are not supported by error logging will be skipped over and not added to the error logging table.<br>When set to FALSE, an unsupported column type will cause the procedure to terminate.<br>The default is FALSE.                                                 |

Examples

First, create an error log table for the channels table in the SH schema, using the default name generation.

Then, see all columns of the table channels:

```
SQL> DESC channels  
Name                               Null?      Type  
-----  
CHANNEL_ID                         NOT NULL   CHAR(1)  
CHANNEL_DESC                       NOT NULL   VARCHAR2(20)  
CHANNEL_CLASS                      VARCHAR2(20)
```

Finally, see all columns of the generated error log table. Note the mandatory control columns that are created by the package:

```
SQL> DESC ERR$_CHANNELS  
Name                               Null?      Type  
-----  
ORA_ERR_NUMBER$                   NUMBER  
ORA_ERR_MSG$                      VARCHAR2(2000)  
ORA_ERR_ROWID$                   ROWID  
ORA_ERR_OPTYP$                   VARCHAR2(2)  
ORA_ERR_TAG$                     VARCHAR2(2000)  
CHANNEL_ID                       VARCHAR2(4000)
```

|               |                 |
|---------------|-----------------|
| CHANNEL_DESC  | VARCHAR2 (4000) |
| CHANNEL_CLASS | VARCHAR2 (4000) |

See *Oracle Database Administrator's Guide* for more information regarding control columns.

# DBMS\_FGA

The `DBMS_FGA` package provides fine-grained security functions.

This chapter contains the following topics:

- [Security Model](#)
- [Operational Notes](#)
- [Summary of DBMS\\_FGA Subprograms](#)

## 72.1 DBMS\_FGA Security Model

You must have the `AUDIT_ADMIN` role or the `EXECUTE` privilege on the `DBMS_FGA` package to create audit policies. `DBMS_FGA` is an invoker rights package.

To analyze and audit data, you must have the `AUDIT_VIEWER` role. Because the audit function can potentially capture all user environment and application context values, policy administration should be executable by privileged users only. The policy event handler module is executed with the module owner's privilege.

## 72.2 DBMS\_FGA Operational Notes

This package is available for only cost-based optimization. The rule-based optimizer may generate unnecessary audit records since audit monitoring can occur before row filtering.

For both the rule-based optimizer and the cost-based optimizer, you can query the `SQL_TEXT` and `SQL_BINDS` columns of the `UNIFIED_AUDIT_TRAIL` view to analyze the SQL text and corresponding bind variables that are issued.

When `DBMS_FGA` executes the policy predicate with the privileges of the user who owns the policy those privileges do not include any default roles that the owner of the policy has, therefore, direct privileges should be granted on the policy. The code that executes the `DBMS_FGA` policy does not establish a session with the default roles of the user who owns the `DBMS_FGA` policy. And so it requires the direct grants on object to policy owner if the policy owner is non-SYS user and policy function is owned by different user.

## 72.3 Summary of DBMS\_FGA Subprograms

This table lists the `DBMS_FGA` subprograms and briefly describes them.

**Table 72-1** *DBMS\_FGA Package Subprograms*

| Subprogram                               | Description                                                                 |
|------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">ADD_POLICY Procedure</a>     | Creates an audit policy using the supplied predicate as the audit condition |
| <a href="#">DISABLE_POLICY Procedure</a> | Disables an audit policy                                                    |

**Table 72-1 (Cont.) DBMS\_FGA Package Subprograms**

| Subprogram                              | Description             |
|-----------------------------------------|-------------------------|
| <a href="#">DROP_POLICY Procedure</a>   | Drops an audit policy   |
| <a href="#">ENABLE_POLICY Procedure</a> | Enables an audit policy |

## 72.3.1 ADD\_POLICY Procedure

This procedure creates an audit policy using the supplied predicate as the audit condition.

### Syntax

```
DBMS_FGA.ADD_POLICY(
    object_schema    IN  VARCHAR2 DEFAULT NULL,
    object_name      IN  VARCHAR2,
    policy_name      IN  VARCHAR2,
    audit_condition  IN  VARCHAR2 DEFAULT NULL,
    audit_column     IN  VARCHAR2 DEFAULT NULL,
    handler_schema   IN  VARCHAR2 DEFAULT NULL,
    handler_module   IN  VARCHAR2 DEFAULT NULL,
    enable           IN  BOOLEAN DEFAULT TRUE,
    statement_types  IN  VARCHAR2 DEFAULT SELECT,
    audit_trail      IN  BINARY_INTEGER DEFAULT NULL,
    audit_column_opts IN  BINARY_INTEGER DEFAULT ANY_COLUMNS,
    policy_owner     IN  VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 72-2 ADD\_POLICY Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_schema   | Schema of the object to be audited. If NULL, the current schema is assumed.                                                                                                                                                                                                   |
| object_name     | Name of the object to be audited                                                                                                                                                                                                                                              |
| policy_name     | Unique name of the policy. Do not enter special characters such as spaces or commas. If you want to use special characters for the policy name, then enclose the name in quotation marks.                                                                                     |
| audit_condition | A condition in a row that indicates a monitoring condition. NULL is allowed and acts as TRUE.                                                                                                                                                                                 |
| audit_column    | Columns to be checked for access. These can include OLS hidden columns or object type columns. The default, NULL, causes audit if any column is accessed or affected.                                                                                                         |
| handler_schema  | Schema that contains the event handler. The default, NULL, causes the current schema to be used.                                                                                                                                                                              |
| handler_module  | Function name of the event handler; includes the package name if necessary. This function is invoked only after the first row that matches the audit condition in the query is processed. If the procedure fails with an exception, the user SQL statement will fail as well. |
| enable          | Enables the policy if TRUE, which is the default                                                                                                                                                                                                                              |
| statement_types | SQL statement types to which this policy is applicable: INSERT, UPDATE, DELETE, or SELECT only                                                                                                                                                                                |

**Table 72-2 (Cont.) ADD\_POLICY Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                           |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>audit_trail</code>       | In an environment that has not yet migrated to unified auditing, the destination (DB or XML) of fine-grained audit records. Also specifies whether to populate the <code>LSQTEXT</code> and <code>LSQLBIND</code> columns in the <code>FGA_LOG\$</code> system table. |
| <code>audit_column_opts</code> | Establishes whether a statement is audited when the query references <i>any</i> column specified in the <code>audit_column</code> parameter or only when <i>all</i> such columns are referenced                                                                       |
| <code>policy_owner</code>      | User who owns the fine-grained auditing policy. However, this setting is not a user-supplied argument. The Oracle Data Pump client uses this setting internally to recreate the fine-grained audit policies appropriately.                                            |

**Usage Notes**

- A table or view can have a maximum of 256 fine-grained audit policies applied to it.
- If `object_schema` is not specified, the current schema is assumed.
- An FGA policy should not be applied to out-of-line columns such as LOB columns.
- Each audit policy is applied to the query individually. However, at most one audit record may be generated for each policy, no matter how many rows being returned satisfy that policy's `audit_condition`. In other words, whenever any number of rows being returned satisfy an audit condition defined on the table, a single audit record will be generated for each such policy.
- If a table with an FGA policy defined on it receives a Fast Path insert or a vectored update, the hint is automatically disabled before any such operations. Disabling the hint allows auditing to occur according to the policy's terms. (One example of a Fast Path insert is the statement `INSERT-WITH-APPEND-hint`.)
- The `audit_condition` must be a boolean expression that can be evaluated using the values in the row being inserted, updated, or deleted. The expression can also use functions, such as the `USER` or `SYS_CONTEXT` functions.

The expression must not combine conditions using operators such as `AND` and `OR`. `audit_condition` can be `NULL` (or omitted), which is interpreted as `TRUE`, but it cannot contain the following elements:

- Subqueries or sequences
- The following attributes of the `USERENV` namespace when accessed using the `SYS_CONTEXT` function:
  - \* `CURRENT_SQL`
  - \* `CURRENT_SQL_LENGTH`
  - \* `CURRENT_BIND`
- Any use of the pseudo columns `LEVEL`, `PRIOR`, or `ROWNUM`.

Specifying an audit condition of `"1=1"` to force auditing of all specified statements ("`statement_types`") affecting the specified column ("`audit_column`") is no longer needed to achieve this purpose. A `NULL` value for `audit_condition` causes audit to happen even if no rows are processed, so that all actions on a table with this policy are audited.

- The `audit_condition` is evaluated using the privileges of the user who creates the policy.
- For the `audit_condition` setting, do not include functions, which execute the auditable statement on the same base table, in the `audit_condition` setting. For example, suppose you create a function that executes an `INSERT` statement on the `HR.EMPLOYEES` table. The policy `audit_condition` contains this function and it is for `INSERT` statements (as set by the `statement_types` parameter). When the policy is used, the function executes recursively until the system has run out of memory. This can raise the error `ORA-1000: maximum open cursors exceeded` or `ORA-00036: maximum number of recursive SQL levels (50) exceeded`.
- Do not issue the `DBMS_FGA.ENABLE_POLICY` or `DBMS_FGA.DISABLE_POLICY` statement from a policy function in a condition.
- The audit function (`handler_module`) is an alerting mechanism for the administrator. The required interface for such a function is as follows:

```
PROCEDURE fname ( object_schema VARCHAR2, object_name VARCHAR2, policy_name
VARCHAR2 ) AS ...
```

where `fname` is the name of the procedure, `object_schema` is the name of the schema of the table audited, `object_name` is the name of the table to be audited, and `policy_name` is the name of the policy being enforced. The audit function will be executed with the function owner's privilege.

- If you have migrated to unified auditing, then omit the `audit_trail` parameter because the audit records will automatically be written to the unified audit trail.
- Be aware that sensitive data, such as credit card information, can be recorded in clear text.
- The `audit_trail` parameter, if used, specifies both where the fine-grained audit trail will be written and whether it is to include the query's SQL Text and SQL Bind variable information (typically in columns named `LSQLTEXT` and `LSQLBIND`):
  - If `audit_trail` includes XML, then fine-grained audit records are written to XML-format operating system files stored in the directory specified by an `AUDIT_FILE_DEST` statement in SQL. (The default `AUDIT_FILE_DEST` is `$ORACLE_BASE/admin/$DB_UNIQUE_NAME/adump` on Unix-based systems, and `$ORACLE_BASE\admin\%DB_UNIQUE_NAME\adump` on Windows systems.)
  - If `audit_trail` includes DB instead, then the audit records are written to the `SYS.FGA_LOG$` table in the database. However, for read-only databases, Oracle Database writes the fine-grained audit records to XML files, regardless of the `audit_trail` settings.
  - If `audit_trail` includes `EXTENDED`, then the query's SQL Text and SQL Bind variable information are included in the audit trail.
  - For example:
    - \* Setting `audit_trail` to `DBMS_FGA.DB` sends the audit trail to the `SYS.FGA_LOG$` table in the database and omits SQL Text and SQL Bind.
    - \* Setting `audit_trail` to `DBMS_FGA.DB + DBMS_FGA.EXTENDED` sends the audit trail to the `SYS.FGA_LOG$` table in the database and includes SQL Text and SQL Bind.
    - \* Setting `audit_trail` to `DBMS_FGA.XML` writes the audit trail in XML files sent to the operating system and omits SQL Text and SQL Bind.
    - \* Setting `audit_trail` to `DBMS_FGA.XML + DBMS_FGA.EXTENDED` writes the audit trail in XML files sent to the operating system and includes SQL Text and SQL Bind.

The `audit_trail` parameter appears in the `ALL_AUDIT_POLICIES` view.

- You can change the operating system destination using the following command:

```
ALTER SYSTEM SET AUDIT_FILE_DEST = New Directory DEFERRED
```

- On many platforms, XML audit files are named `process_name_processId.xml`, for example, `ora_2111.xml`. Alternatively, on Windows, the XML audit files are named `process_name_ThreadId.xml` (or `process_name_ProcessId.xml` if the process is not running as a thread).
- The `audit_column_opts` parameter establishes whether a statement is audited
  - when the query references *any* column specified in the `audit_column` parameter (`audit_column_opts = DBMS_FGA.ANY_COLUMNS`), or
  - only when *all* such columns are referenced (`audit_column_opts = DBMS_FGA.ALL_COLUMNS`).

The default is `DBMS_FGA.ANY_COLUMNS`.

The `ALL_AUDIT_POLICIES` view also shows `audit_column_opts`.

- When `audit_column_opts` is set to `DBMS_FGA.ALL_COLUMNS`, a SQL statement is audited only when all the columns mentioned in `audit_column` have been explicitly referenced in the statement. And these columns must be referenced in the same SQL-statement or in the sub-select.

All these columns must refer to a single table/view or alias.

If a SQL statement selects the columns from different table aliases, the statement will not be audited.

- Every XML audit record contains the elements `AUDIT_TYPE` and `EXTENDED_TIMESTAMP`, with the latter printed in UTC zone (with no timezone information). Values retrieved using `V$XML_AUDIT_TRAIL` view are converted to session timezone and printed.
- For `SQL_TEXT` and `SQL_BIND` element values (CLOB type columns), the dynamic view shows only the first 4000 characters. The underlying XML file may have more than 4000 characters for such `SQL_TEXT` and `SQL_BIND` values.
- For large numbers of XML audit files, querying `V$XML_AUDIT_TRAIL` is faster when they are loaded into a database table using `SQL*Loader` or a similar tool. XML audit files are larger than the equivalent written to OS files when `AUDIT_TRAIL=OS`.
- Error handling is the same as when `AUDIT_TRAIL=OS`. If any error occurs in writing an audit record to disk, including the directory identified by `AUDIT_FILE_DEST` being full, the auditing operation fails. An alert message is logged.
- The policy event handler module will be executed with the module owner's privilege.
- If the owner of an audit policy is different from the owner of the policy function in the audit condition, then you must grant the privilege to execute the policy function directly to the policy owner instead of through the role. Otherwise, the policy function fails to execute and raises `ORA-28138`.

For example, if an audit policy is owned by a non-SYS user and a policy function in the audit condition is a definer's rights function owned by another user (User A), you should grant the execute privilege of the policy function directly to User A.

- Do not create recursive fine-grained audit handlers. For example, suppose you create a handler that executes an `INSERT` statement on the `HR.EMPLOYEES` table. The policy that is associated with this handler is for `INSERT` statements (as set by the `statement_types` parameter). When the policy is used, the handler executes recursively until the system has

run out of memory. This can raise the error ORA-1000: maximum open cursors exceeded or ORA-00036: maximum number of recursive SQL levels (50) exceeded. **See also** *Oracle Database Security Guide* with regard to Creating a Fine-Grained Audit Policy.

- The fine-grained audit handler module should not have explicit COMMIT, ROLLBACK, and DDL statements mentioned in it.
- The values for the `audit_trail` parameter (XML and XML+EXTENDED) cause fine-grained auditing records to be written to operating system files in XML format. A dynamic view, `V$XML_AUDIT_TRAIL`, makes such audit records from XML files available to DBAs through SQL query, providing enhanced usability. Querying this view causes all XML files (all files with an .xml extension) in the `AUDIT_FILE_DEST` directory to be parsed and presented in relational table format.

Audit records stored in operating system files can be more secure than database-stored audit records because access can require file permissions that DBAs do not have. Operating system storage for audit records also offers higher availability, since such records remain available even if the database is temporarily inaccessible.

The `DBA_COMMON_AUDIT_TRAIL` view includes the contents of the `V$XML_AUDIT_TRAIL` dynamic view for standard and fine-grained audit records.

Note that the `V$XML_AUDIT_TRAIL` view is populated only if unified auditing is not enabled. If you have enabled unified auditing, then you can query the `UNIFIED_AUDIT_TRAIL` data dictionary view for the audit trail records.

*Oracle Database Security Guide* for an example of creating an email alert handler for a fine-grained audit policy

### Examples

```
DBMS_FGA.ADD_POLICY (
  object_schema    => 'scott',
  object_name      => 'emp',
  policy_name      => 'mypolicy1',
  audit_condition  => 'sal < 100',
  audit_column     => 'comm,sal',
  handler_schema   => NULL,
  handler_module   => NULL,
  enable          => TRUE,
  statement_types  => 'INSERT, UPDATE',
  audit_column_opts => DBMS_FGA.ANY_COLUMNS,
  policy_owner     => 'sec_admin');
```

## 72.3.2 DISABLE\_POLICY Procedure

This procedure disables an audit policy.

### Syntax

```
DBMS_FGA.DISABLE_POLICY(
  object_schema IN VARCHAR2,
  object_name   IN VARCHAR2,
  policy_name   IN VARCHAR2);
```

## Parameters

**Table 72-3** DISABLE\_POLICY Procedure Parameters

| Parameter     | Description                                                                 |
|---------------|-----------------------------------------------------------------------------|
| object_schema | Schema of the object to be audited. If NULL, the current schema is assumed. |
| object_name   | Name of the object to be audited                                            |
| policy_name   | Unique name of the policy                                                   |

The default value for object\_schema is NULL. If NULL, the current schema is assumed.

## Examples

```
DBMS_FGA.DISABLE_POLICY (  
  object_schema => 'scott',  
  object_name   => 'emp',  
  policy_name   => 'mypolicy1');
```

## 72.3.3 DROP\_POLICY Procedure

This procedure drops an audit policy.

## Syntax

```
DBMS_FGA.DROP_POLICY(  
  object_schema IN VARCHAR2,  
  object_name   IN VARCHAR2,  
  policy_name   IN VARCHAR2);
```

## Parameters

**Table 72-4** DROP\_POLICY Procedure Parameters

| Parameter     | Description                                                                 |
|---------------|-----------------------------------------------------------------------------|
| object_schema | Schema of the object to be audited. If NULL, the current schema is assumed. |
| object_name   | Name of the object to be audited                                            |
| policy_name   | Unique name of the policy                                                   |

## Usage Notes

The DBMS\_FGA procedures cause current DML transactions, if any, to commit before the operation unless they are inside a DDL event trigger. With DDL transactions, the DBMS\_FGA procedures are part of the DDL transaction. The default value for object\_schema is NULL. If NULL, the current schema is assumed.

**Note:**

Oracle Database automatically drops the audit policy if you remove the object specified in the `object_name` parameter of the `DBMS_FGA.ADD_POLICY` procedure, or if you drop the user who created the audit policy.

**Examples**

```
DBMS_FGA.DROP_POLICY (  
  object_schema => 'scott',  
  object_name   => 'emp',  
  policy_name   => 'mypolicy1');
```

## 72.3.4 ENABLE\_POLICY Procedure

This procedure enables an audit policy.

**Syntax**

```
DBMS_FGA.ENABLE_POLICY(  
  object_schema IN VARCHAR2,  
  object_name   IN VARCHAR2,  
  policy_name   IN VARCHAR2,  
  enable        IN BOOLEAN);
```

**Parameters**

**Table 72-5** ENABLE\_POLICY Procedure Parameters

| Parameter     | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| object_schema | Schema of the object to be audited. If <code>NULL</code> , the current schema is assumed. |
| object_name   | Name of the object to be audited                                                          |
| policy_name   | Unique name of the policy                                                                 |
| enable        | Defaults to <code>TRUE</code> to enable the policy                                        |

**Examples**

```
DBMS_FGA.ENABLE_POLICY (  
  object_schema => 'scott',  
  object_name   => 'emp',  
  policy_name   => 'mypolicy1',  
  enable        => TRUE);
```

# DBMS\_FILE\_GROUP

The `DBMS_FILE_GROUP` package, one of a set of Oracle Streams packages, provides administrative interfaces for managing file groups, file group versions, and files. A file group repository is a collection of all of the file groups in a database and can contain multiple versions of a particular file group. You can use this package to create and manage file group repositories.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_FILE\\_GROUP Subprograms](#)

## 73.1 DBMS\_FILE\_GROUP Overview

It is helpful to understand terminology before using the `DBMS_FILE_GROUP` package.

The following terms pertain to the `DBMS_FILE_GROUP` package:

### File

A **file** is a reference to a file stored on hard disk. A file is composed of a file name, a directory object, and a file type. The directory object references the directory in which the file is stored on hard disk. For example, a file might have the following components:

- The file name is `expdat.dmp`.
- The directory object that contains the file is `db_files`.
- The file type is `DBMS_FILE_GROUP.EXPORT_DUMP_FILE`.

### Version

A **version** is a collection of related files. For example, a version might consist of a set of data files and a Data Pump export dump file generated by a Data Pump transportable tablespace export. Only one Data Pump export dump file is allowed in a version.

### File Group

A **file group** is a collection of versions. A file group can logically group a set of versions. For example, a file group named `financial_quarters` can keep track of quarterly financial data by logically grouping versions of files related to a tablespace set. The tablespaces containing the data can be exported at the end of each quarter and versioned under names such as `Q1FY04`, `Q2FY04`, and so on.

## 73.2 DBMS\_FILE\_GROUP Security Model

There are two ways to define control on the DBMS\_FILE\_GROUP package.

- Granting `EXECUTE` on this package to selected users or roles.
- Granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

## 73.3 DBMS\_FILE\_GROUP Constants

The `DBMS_FILE_GROUP` package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name. For example, `DBMS_FILE_GROUP.EXPORT_DUMP_FILE`.

The following table lists the parameters and enumerated constants.

**Table 73-1 DBMS\_FILE\_GROUP Parameters with Enumerated Constants**

| Parameter                      | Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_type                      | <ul style="list-style-type: none"> <li>• <code>DATAFILE</code></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                     | <code>VARCHAR2 (30)</code>  | <code>DATAFILE</code> is a datafile for a database. This constant can be specified as <code>'DATAFILE'</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 73.4 Summary of DBMS\_FILE\_GROUP Subprograms

This table lists the DBMS\_FILE\_GROUP subprograms and briefly describes them.

**Table 73-2 DBMS\_FILE\_GROUP Package Subprograms**

| Subprogram                                        | Description                                                     |
|---------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">ADD_FILE Procedure</a>                | Adds a file to a version of a file group                        |
| <a href="#">ALTER_FILE Procedure</a>              | Alters a file in a version of a file group                      |
| <a href="#">ALTER_FILE_GROUP Procedure</a>        | Alters a file group                                             |
| <a href="#">ALTER_VERSION Procedure</a>           | Alters a version of a file group                                |
| <a href="#">CREATE_FILE_GROUP Procedure</a>       | Creates a file group                                            |
| <a href="#">CREATE_VERSION Procedure</a>          | Creates a version of a file group                               |
| <a href="#">DROP_FILE_GROUP Procedure</a>         | Drops a file group                                              |
| <a href="#">DROP_VERSION Procedure</a>            | Drops a version of a file group                                 |
| <a href="#">GRANT_OBJECT_PRIVILEGE Procedure</a>  | Grants object privileges on a file group to a user              |
| <a href="#">GRANT_SYSTEM_PRIVILEGE Procedure</a>  | Grants system privileges for file group operations to a user    |
| <a href="#">PURGE_FILE_GROUP Procedure</a>        | Purges a file group using the file group's retention policy     |
| <a href="#">REMOVE_FILE Procedure</a>             | Removes a file from a version of a file group                   |
| <a href="#">REVOKE_OBJECT_PRIVILEGE Procedure</a> | Revokes object privileges on a file group from a user           |
| <a href="#">REVOKE_SYSTEM_PRIVILEGE Procedure</a> | Revokes system privileges for file group operations from a user |

### Note:

All subprograms commit unless specified otherwise.

### 73.4.1 ADD\_FILE Procedure

This procedure adds a file to a version of a file group.

#### Syntax

```
DBMS_FILE_GROUP.ADD_FILE(  
    file_group_name IN VARCHAR2,  
    file_name       IN VARCHAR2,  
    file_type       IN VARCHAR2 DEFAULT NULL,  
    file_directory  IN VARCHAR2 DEFAULT NULL,  
    version_name    IN VARCHAR2 DEFAULT NULL,  
    comments        IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 73-3 ADD\_FILE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name | The name of the file group that contains the version, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| file_name       | The name of the file being added to the version. Each file name in a version must be unique.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| file_type       | <p>The file type. The following are reserved file types:</p> <ul style="list-style-type: none"> <li>If the file is a datafile, then enter the following:<br/><code>'DATAFILE'</code></li> <li>If the file is a Data Pump export dump file, then enter the following:<br/><code>'DUMPSET'</code></li> </ul> <p>Data Pump metadata is populated when a Data Pump export dump file is imported.</p> <ul style="list-style-type: none"> <li>If the file is a Data Pump export log file, then enter the following:<br/><code>'DATAPUMPLOG'</code></li> </ul> <p>If the file type is not one of the reserved file types, then either enter a text description of the file type, or specify <code>NULL</code> to omit a file type description. See "<a href="#">Constants</a>" for more information about the reserved file types.</p> |
| file_directory  | <p>The name of the directory object that corresponds to the directory containing the file.</p> <p>If <code>NULL</code>, then the procedure uses the default directory object for the version.</p> <p>If <code>NULL</code> and no default directory object exists for the version, then the procedure uses the default directory object for the file group.</p> <p>If <code>NULL</code> and no default directory object exists for the version or file group, then the procedure raises an error.</p>                                                                                                                                                                                                                                                                                                                            |
| version_name    | <p>The name of the version to which the file is added.</p> <p>If a positive integer is specified as a <code>VARCHAR2</code> value, then the integer is interpreted as a version number. For example, if <code>'1'</code> is specified, then the file is added to version 1 of the file group.</p> <p>If <code>NULL</code>, then the procedure uses the version with the latest creation time for the file group.</p>                                                                                                                                                                                                                                                                                                                                                                                                            |
| comments        | Comments about the file being added                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Usage Notes

To run this procedure with either `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `'DUMPSET'` specified for the `file_type` parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have `READ` privilege on the directory object that contains the Data Pump export dump file

**See Also:**

*Oracle Database Utilities* for more information about Data Pump privileges

## 73.4.2 ALTER\_FILE Procedure

This procedure alters a file in a version of a file group.

### Syntax

```
DBMS_FILE_GROUP.ALTER_FILE(  
    file_group_name    IN  VARCHAR2,  
    file_name          IN  VARCHAR2,  
    version_name       IN  VARCHAR2  DEFAULT NULL,  
    new_file_name       IN  VARCHAR2  DEFAULT NULL,  
    new_file_directory IN  VARCHAR2  DEFAULT NULL,  
    new_file_type       IN  VARCHAR2  DEFAULT NULL,  
    remove_file_type   IN  VARCHAR2  DEFAULT 'N',  
    new_comments       IN  VARCHAR2  DEFAULT NULL,  
    remove_comments    IN  VARCHAR2  DEFAULT 'N');
```

### Parameters

**Table 73-4 ALTER\_FILE Procedure Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name    | The name of the file group that contains the version, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default.                                                                                                                          |
| file_name          | The name of the file being altered in the version                                                                                                                                                                                                                                                                                                                                                                                                           |
| version_name       | The name of the version that contains the file being altered.<br>If a positive integer is specified as a <code>VARCHAR2</code> value, then the integer is interpreted as a version number. For example, if '1' is specified, then the file in version 1 of the file group is altered.<br>If <code>NULL</code> , then the procedure uses the version with the latest creation time for the file group.                                                       |
| new_file_name      | The new name of the file if the file name is being changed. Each file name in a version must be unique.<br>If <code>NULL</code> , then the procedure does not change the file name.<br><b>Note:</b> When a non- <code>NULL</code> new file name is specified, this procedure changes the metadata for the file name in the data dictionary, but it does not change the file name on the hard disk.                                                          |
| new_file_directory | The new name of the directory object that corresponds to the directory containing the file, if the directory object is being changed.<br>If <code>NULL</code> , then the procedure does not change the directory object name.<br><b>Note:</b> When a non- <code>NULL</code> new file directory is specified, this procedure changes the metadata for the file directory in the data dictionary, but it does not change the file directory on the hard disk. |

**Table 73-4 (Cont.) ALTER\_FILE Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>new_file_type</code>    | <p>The file type. The following are reserved file types:</p> <ul style="list-style-type: none"> <li>If the file is a datafile, then enter the following:<br/>'DATAFILE'</li> <li>If the file is a Data Pump export dump file, then enter the following:<br/>'DUMPSET'</li> <li>If the file is a Data Pump export log file, then enter the following:<br/>'DATAPUMPLOG'</li> </ul> <p>If the file type is not one of the reserved file types, then enter a text description of the file type.</p> <p>If NULL, then the procedure does not change the file type.</p> <p><b>See Also:</b> "Constants" for more information about the reserved file types.</p> |
| <code>remove_file_type</code> | <p>If Y, then the procedure removes the file type. If Y and the <code>new_file_type</code> parameter is non-NULL, then the procedure raises an error.</p> <p>If N, then the procedure does not remove the file type.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>new_comments</code>     | <p>New comments about the file being altered. If non-NULL, then the procedure replaces the existing comments with the specified comments.</p> <p>If NULL, then the procedure does not change the existing comments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>remove_comments</code>  | <p>If Y, then the procedure removes the comments for the file. If Y and the <code>new_comments</code> parameter is non-NULL, then the procedure raises an error.</p> <p>If N, then the procedure does not change the existing comments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                |

### Usage Notes

If the file type is changed to `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or 'DUMPSET', then Data Pump metadata for the file is populated. If the file type is changed from `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or 'DUMPSET', then Data Pump metadata for the file is purged.

To run this procedure with `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or 'DUMPSET' specified for the `new_file_type` parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have READ privilege on the directory object that contains the Data Pump export dump file

#### See Also:

*Oracle Database Utilities* for more information about Data Pump privileges

### 73.4.3 ALTER\_FILE\_GROUP Procedure

This procedure alters a file group.

#### Syntax

```
DBMS_FILE_GROUP.ALTER_FILE_GROUP(  
    file_group_name      IN  VARCHAR2,  
    keep_files           IN  VARCHAR2  DEFAULT NULL,  
    min_versions         IN  NUMBER    DEFAULT NULL,  
    max_versions         IN  NUMBER    DEFAULT NULL,  
    retention_days       IN  NUMBER    DEFAULT NULL,  
    new_default_directory IN  VARCHAR2  DEFAULT NULL,  
    remove_default_directory IN VARCHAR2  DEFAULT 'N',  
    new_comments         IN  VARCHAR2  DEFAULT NULL,  
    remove_comments      IN  VARCHAR2  DEFAULT 'N');
```

#### Parameters

**Table 73-5 ALTER\_FILE\_GROUP Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name | The name of the file group being altered, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <i>hq_dba</i> and the file group name is <i>sales_tbs</i> , then specify <i>hq_dba.sales_tbs</i> . If the schema is not specified, then the current user is the default.                                                                                                                                                                                                                                    |
| keep_files      | If Y, then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged.<br>If N, then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged.<br>If NULL, then this parameter is not changed.<br><b>Note:</b> If the file group is dropped because of a <code>DROP USER CASCADE</code> statement, then the setting of this parameter determines whether the files are dropped from the hard disk. |
| min_versions    | The minimum number of versions to retain. The specified value must be greater than or equal to 1.<br>If NULL, then the procedure does not change the <code>min_versions</code> setting for the file group.                                                                                                                                                                                                                                                                                                                              |
| max_versions    | The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for <code>min_versions</code> . When the number of versions exceeds the specified <code>max_versions</code> , the oldest version is purged.<br>Specify <code>DBMS_FILE_GROUP.INFINITE</code> for no limit to the number of versions.<br>If NULL, then the procedure does not change the <code>max_versions</code> setting for the file group.                                                                        |

**Table 73-5 (Cont.) ALTER\_FILE\_GROUP Procedure Parameters**

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>retention_days</code>           | <p>The maximum number of days to retain a version. The specified value must be greater than or equal to 0 (zero). When the age of a version exceeds the specified <code>retention_days</code> and there are more versions than the number specified in <code>min_versions</code>, the version is purged. The age of a version is calculated by subtracting the creation time from the current time.</p> <p>A decimal value can specify a fraction of a day. For example, 1.25 specifies one day and six hours.</p> <p>Specify <code>DBMS_FILE_GROUP.INFINITE</code> for no limit to the number of days a version can exist.</p> <p>If NULL, then the procedure does not change the <code>retention_days</code> setting for the file group.</p> |
| <code>new_default_directory</code>    | <p>The default directory object used when files are added to a file group if no directory is specified when the files are added, and no default directory object is specified for the version.</p> <p>If NULL, then the procedure does not change the default directory.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>remove_default_directory</code> | <p>If Y, then the procedure removes the default directory for the file group. If Y and the <code>new_default_directory</code> parameter is set to a non-NULL value, then the procedure raises an error.</p> <p>If N, then the procedure does not remove the default directory for the file group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>new_comments</code>             | <p>Comments about the file group. If non-NULL, then the new comments replace the existing comments for the file group.</p> <p>If NULL, then the procedure does not change the existing comments.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>remove_comments</code>          | <p>If Y, then the comments for the file group are removed. If Y and the <code>new_comments</code> parameter is set to a non-NULL value, then the procedure raises an error.</p> <p>If N, then the procedure does not change the comments for the file group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Usage Notes

If `min_versions` is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set `min_versions` to at least 2 if a version of the file group must be available at all times.

## 73.4.4 ALTER\_VERSION Procedure

This procedure alters a version of a file group.

### Syntax

```
DBMS_FILE_GROUP.ALTER_VERSION(
    file_group_name          IN  VARCHAR2,
    version_name             IN  VARCHAR2  DEFAULT NULL,
    new_version_name         IN  VARCHAR2  DEFAULT NULL,
    remove_version_name      IN  VARCHAR2  DEFAULT 'N',
```

```
new_default_directory IN VARCHAR2 DEFAULT NULL,
remove_default_directory IN VARCHAR2 DEFAULT 'N',
new_comments IN VARCHAR2 DEFAULT NULL,
remove_comments IN VARCHAR2 DEFAULT 'N');
```

## Parameters

**Table 73-6 ALTER\_VERSION Procedure Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name          | The name of the file group that contains the version, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <i>hq_dba</i> and the file group name is <i>sales_tbs</i> , then specify <i>hq_dba.sales_tbs</i> . If the schema is not specified, then the current user is the default.                                                                                                                                                                                                           |
| version_name             | The name of the version being altered.<br><br>If a positive integer is specified as a <code>VARCHAR2</code> value, then the integer is interpreted as a version number. For example, if '1' is specified, then version 1 of the file group is altered.<br><br>If '*' is specified, then the procedure alters all versions, and the <code>new_version_name</code> parameter must be <code>NULL</code> .<br><br>If <code>NULL</code> , then the procedure uses the version with the latest creation time for the file group. |
| new_version_name         | The new name of the version. Do not specify a schema.<br><br>The specified version name cannot be a positive integer or an asterisk ('*').<br><br>If <code>NULL</code> , then the procedure does not change the version name.                                                                                                                                                                                                                                                                                              |
| remove_version_name      | If <code>Y</code> , then the procedure removes the version name. If the version name is removed, then the version number must be used to manage the version. If <code>Y</code> and the <code>new_version_name</code> parameter is set to a non- <code>NULL</code> value, then the procedure raises an error.<br><br>If <code>N</code> , then the procedure does not remove the version name.                                                                                                                               |
| new_default_directory    | The default directory object used when files are added to a version if no directory is specified when the files are added.<br><br>If <code>NULL</code> , then the procedure does not change the default directory.                                                                                                                                                                                                                                                                                                         |
| remove_default_directory | If <code>Y</code> , then the procedure removes the default directory. If <code>Y</code> and the <code>new_default_directory</code> parameter is set to a non- <code>NULL</code> value, then the procedure raises an error.<br><br>If <code>N</code> , then the procedure does not remove the default directory.                                                                                                                                                                                                            |
| new_comments             | Comments about the version. If non- <code>NULL</code> , then the new comments replace the existing comments for the version.<br><br>If <code>NULL</code> , then the procedure does not change the comments.                                                                                                                                                                                                                                                                                                                |
| remove_comments          | If <code>Y</code> , then the procedure removes the comments for the version. If <code>Y</code> and the <code>new_comments</code> parameter is set to a non- <code>NULL</code> value, then the procedure raises an error.<br><br>If <code>N</code> , then the procedure does not remove the comments for the version.                                                                                                                                                                                                       |

## 73.4.5 CREATE\_FILE\_GROUP Procedure

This procedure creates a file group.

### Syntax

```
DBMS_FILE_GROUP.CREATE_FILE_GROUP(
    file_group_name    IN  VARCHAR2,
    keep_files         IN  VARCHAR2  DEFAULT 'Y',
    min_versions        IN  NUMBER    DEFAULT 2,
    max_versions        IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
    retention_days      IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
    default_directory   IN  VARCHAR2  DEFAULT NULL,
    comments           IN  VARCHAR2  DEFAULT NULL);
```

### Parameters

**Table 73-7 CREATE\_FILE\_GROUP Procedure Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name   | The name of the file group, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <i>hq_dba</i> and the file group name is <i>sales_tbs</i> , then specify <i>hq_dba.sales_tbs</i> . If the schema is not specified, then the current user is the default.                                                                                                                                                                                                                                                                                                          |
| keep_files        | If <i>Y</i> , then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged.<br>If <i>N</i> , then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged.<br><b>Note:</b> If the file group is dropped because of a <i>DROP USER CASCADE</i> statement, then the setting of this parameter determines whether the files are dropped from the hard disk.                                                                                               |
| min_versions      | The minimum number of versions to retain. The specified value must be greater than or equal to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| max_versions      | The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for <i>min_versions</i> . When the number of versions exceeds the specified <i>max_versions</i> , the oldest version is purged.<br>Specify <i>DBMS_FILE_GROUP.INFINITE</i> for no limit to the number of versions.                                                                                                                                                                                                                                                           |
| retention_days    | The maximum number of days to retain a version. The specified value must be greater than or equal to 0 (zero). When the age of a version exceeds the specified <i>retention_days</i> and there are more versions than the number specified in <i>min_versions</i> , the version is purged. The age of a version is calculated by subtracting the creation time from the current time.<br>A decimal value can specify a fraction of a day. For example, 1.25 specifies one day and six hours.<br>Specify <i>DBMS_FILE_GROUP.INFINITE</i> for no limit to the number of days a version can exist. |
| default_directory | The default directory object used when files are added to a file group if no directory is specified when the files are added, and no default directory object is specified for the version.                                                                                                                                                                                                                                                                                                                                                                                                     |
| comments          | Comments about the file group being created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Usage Notes

If `min_versions` is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set `min_versions` to at least 2 if a version of the file group must be available at all times.

73.4.6 CREATE\_VERSION Procedure

This procedure creates a version of a file group.

This procedure automatically runs the `PURGE_FILE_GROUP` procedure. Therefore, versions can be purged based on the file group's retention policy.

This procedure is overloaded. One version of the procedure contains the `OUT` parameter `version_out`, and the other does not.

Syntax

```
DBMS_FILE_GROUP.CREATE_VERSION(  
    file_group_name    IN   VARCHAR2,  
    version_name       IN   VARCHAR2 DEFAULT NULL,  
    default_directory  IN   VARCHAR2 DEFAULT NULL,  
    comments           IN   VARCHAR2 DEFAULT NULL);  
  
DBMS_FILE_GROUP.CREATE_VERSION(  
    file_group_name    IN   VARCHAR2,  
    version_name       IN   VARCHAR2 DEFAULT NULL,  
    default_directory  IN   VARCHAR2 DEFAULT NULL,  
    comments           IN   VARCHAR2 DEFAULT NULL,  
    version_out        OUT  VARCHAR2);
```

Parameters

Table 73-8 CREATE\_VERSION Procedure Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name   | The name of the file group to which the new version is added, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default. |
| version_name      | The name of the version being created. Do not specify a schema.<br>The specified version name cannot be a positive integer because, when a version is created, a version number is generated automatically. The specified version name cannot be an asterisk ('*').                                                                        |
| default_directory | The default directory object used when files are added to a version if no directory is specified when the files are added.                                                                                                                                                                                                                 |
| comments          | Comments about the version being created                                                                                                                                                                                                                                                                                                   |
| version_out       | If the <code>version_name</code> parameter is set to a non-NULL value, then this parameter contains the specified version name.<br>If the <code>version_name</code> parameter is set to NULL, then this parameter contains the generated version number.                                                                                   |

## 73.4.7 DROP\_FILE\_GROUP Procedure

This procedure drops a file group.

### Syntax

```
DBMS_FILE_GROUP.DROP_FILE_GROUP(  
    file_group_name IN VARCHAR2,  
    keep_files      IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 73-9 DROP\_FILE\_GROUP Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name | The name of the file group being dropped, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default. |
| keep_files      | If <code>Y</code> , then the procedure retains the files in the file group on hard disk.<br>If <code>N</code> , then the procedure deletes the files in the file group from hard disk.<br>If <code>NULL</code> , then the procedure uses the default keep files property of the file group.                            |

### Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.

## 73.4.8 DROP\_VERSION Procedure

This procedure drops a version of a file group.

### Syntax

```
DBMS_FILE_GROUP.DROP_VERSION(  
    file_group_name IN VARCHAR2,  
    version_name    IN VARCHAR2 DEFAULT NULL,  
    keep_files      IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 73-10 DROP\_VERSION Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_group_name | The name of the file group that contains the version, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default.                                                                                   |
| version_name    | The name of the version being dropped.<br>If a positive integer is specified as a <code>VARCHAR2</code> value, then the integer is interpreted as a version number. For example, if '1' is specified, then version 1 of the file group is dropped.<br>If <code>NULL</code> , then the procedure uses the version with the oldest creation time for the file group.<br>If '*', then the procedure drops all versions. |
| keep_files      | If <code>Y</code> , then the procedure retains the files in the version on hard disk.<br>If <code>N</code> , then the procedure deletes the files in the version from hard disk.<br>If <code>NULL</code> , then the procedure uses the default keep files property of the file group.                                                                                                                                |

## Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.

## 73.4.9 GRANT\_OBJECT\_PRIVILEGE Procedure

This procedure grants object privileges on a file group to a user.

## Syntax

```
DBMS_FILE_GROUP.GRANT_OBJECT_PRIVILEGE(
  object_name  IN  VARCHAR2,
  privilege    IN  BINARY_INTEGER,
  grantee      IN  VARCHAR2,
  grant_option IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 73-11 GRANT\_OBJECT\_PRIVILEGE Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_name | The name of the file group on which the privilege is granted, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default. |
| privilege   | The constant that specifies the privilege. See " <a href="#">Constants</a> " for valid privileges.                                                                                                                                                                                                                                         |
| grantee     | The name of the user or role for which the privilege is granted. The specified user cannot be the owner of the object.                                                                                                                                                                                                                     |

**Table 73-11 (Cont.) GRANT\_OBJECT\_PRIVILEGE Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grant_option | If TRUE, then the specified user granted the specified privilege can grant this privilege to others.<br>If FALSE, then the specified user granted the specified privilege cannot grant this privilege to others. |

**Usage Notes**

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the object on which the privilege is granted
- Have the same privilege as the privilege being granted with the grant option

## 73.4.10 GRANT\_SYSTEM\_PRIVILEGE Procedure

This procedure grants system privileges for file group operations to a user.

**Syntax**

```
DBMS_FILE_GROUP.GRANT_SYSTEM_PRIVILEGE(  
    privilege      IN  BINARY_INTEGER,  
    grantee       IN  VARCHAR2,  
    grant_option  IN  BOOLEAN  DEFAULT FALSE);
```

**Parameters****Table 73-12 GRANT\_SYSTEM\_PRIVILEGE Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| privilege    | The constant that specifies the privilege. See " <a href="#">Constants</a> " for valid privileges.                                                                                                               |
| grantee      | The name of the user or role for which the privilege is granted. The user who runs the procedure cannot be specified.                                                                                            |
| grant_option | If TRUE, then the specified user granted the specified privilege can grant this privilege to others.<br>If FALSE, then the specified user granted the specified privilege cannot grant this privilege to others. |

## 73.4.11 PURGE\_FILE\_GROUP Procedure

This procedure purges a file group using the file group's retention policy.

A file group's retention policy is determined by its settings for the `max_versions`, `min_versions`, and `retention_days` parameters. The following versions of a file group are removed when a file group is purged:

- All versions greater than the `max_versions` setting for the file group when versions are ordered in descending order by creation time. Therefore, the older versions are purged before the newer versions.

- All versions older than the `retention_days` setting for the file group unless purging a version would cause the number of versions to drop below the `min_versions` setting for the file group.

A job named `SYS.FGR$AUTOPURGE_JOB` automatically purges all file groups in a database periodically according to the job's schedule. You can adjust this job's schedule using the `DBMS_SCHEDULER` package. Alternatively, you can create a job that runs the `PURGE_FILE_GROUP` procedure periodically.

### Syntax

```
DBMS_FILE_GROUP.PURGE_FILE_GROUP(  
    file_group_name IN VARCHAR2);
```

### Parameter

**Table 73-13** PURGE\_FILE\_GROUP Procedure Parameter

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file_group_name</code> | The name of the file group, specified as <code>[schema_name.]file_group_name</code> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default.<br><br>If <code>NULL</code> and this procedure is run by <code>SYS</code> user, then the procedure purges all file groups. |

### Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files. Files are deleted when a version is purged and the `keep_files` parameter is set to `N` for the version's file group.

## 73.4.12 REMOVE\_FILE Procedure

This procedure removes a file from a version of a file group.

### Syntax

```
DBMS_FILE_GROUP.REMOVE_FILE(  
    file_group_name IN VARCHAR2,  
    file_name       IN VARCHAR2,  
    version_name    IN VARCHAR2 DEFAULT NULL,  
    keep_file       IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 73-14** REMOVE\_FILE Procedure Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file_group_name</code> | The name of the file group that contains the version, specified as <code>[schema_name.]file_group_name</code> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default. |
| <code>file_name</code>       | The name of the file being removed from the version                                                                                                                                                                                                                                                                                      |

**Table 73-14 (Cont.) REMOVE\_FILE Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| version_name | The name of the version from which the file is removed.<br><br>If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then the file is removed from version 1 of the file group.<br><br>If NULL, then the procedure uses the version with the latest creation time for the file group.<br><br>If '*', then the procedure removes the file from all versions. |
| keep_file    | If Y, then the procedure retains the file on hard disk.<br><br>If N, then the procedure deletes the file from hard disk.<br><br>If NULL, then the procedure uses the default keep files property of the file group.                                                                                                                                                                                                                                  |

**Usage Notes**

If this procedure deletes files on hard disk, then the user who runs the procedure must have **WRITE** privilege on the directory object that contains the files.

## 73.4.13 REVOKE\_OBJECT\_PRIVILEGE Procedure

This procedure revokes object privileges on a file group from a user.

**Syntax**

```
DBMS_FILE_GROUP.REVOKE_OBJECT_PRIVILEGE(  
  object_name IN VARCHAR2,  
  privilege   IN BINARY_INTEGER,  
  revokee     IN VARCHAR2);
```

**Parameters****Table 73-15 REVOKE\_OBJECT\_PRIVILEGE Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_name | The name of the file group on which the privilege is revoked, specified as <i>[schema_name.]file_group_name</i> . For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code> , then specify <code>hq_dba.sales_tbs</code> . If the schema is not specified, then the current user is the default. |
| privilege   | The constant that specifies the privilege. See " <a href="#">Constants</a> " for valid privileges.                                                                                                                                                                                                                                         |
| revokee     | The name of the user or role from which the privilege is revoked. The user who owns the object cannot be specified.                                                                                                                                                                                                                        |

## 73.4.14 REVOKE\_SYSTEM\_PRIVILEGE Procedure

This procedure revokes system privileges for file group operations from a user.

### Syntax

```
DBMS_FILE_GROUP.REVOKE_SYSTEM_PRIVILEGE(  
    privilege IN BINARY_INTEGER,  
    revokee   IN VARCHAR2);
```

### Parameters

**Table 73-16 REVOKE\_SYSTEM\_PRIVILEGE Procedure Parameters**

| Parameter | Description                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------|
| privilege | The constant that specifies the privilege. See " <a href="#">Constants</a> " for valid privileges.                     |
| revokee   | The name of the user or role from which the privilege is revoked. The user who runs the procedure cannot be specified. |

# DBMS\_FILE\_TRANSFER

The `DBMS_FILE_TRANSFER` package provides procedures to copy a binary file within a database or to transfer a binary file between databases.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Operating Notes](#)
- [Summary of DBMS\\_FILE\\_TRANSFER Subprograms](#)

## See Also:

*Oracle Database Administrator's Guide* for instructions about using file transfer

## 74.1 DBMS\_FILE\_TRANSFER Overview

The `DBMS_FILE_TRANSFER` package provides procedures to copy a binary file within a database or to transfer a binary file between databases.

The destination database converts each block when it receives a file from a platform with different endianness. Datafiles can be imported after they are moved to the destination database as part of a transportable operation without RMAN conversion. Both `GET` and `PUT` operations will convert the file across platform difference at the destination. However, `COPY` is a local operation and therefore no conversion is required.

## 74.2 DBMS\_FILE\_TRANSFER Security Model

The `DBMS_FILE_TRANSFER` package must be created under `SYS` (`CONNECT INTERNAL`). Operations provided by this package are performed under the current calling user, not the package owner (`SYS`).

To use this interface the following users must have the following privileges:

- The current user at the local database must have `READ` privilege on the directory object specified in the `source_directory_object` parameter.
- The connected user at the destination database must have `WRITE` privilege to the directory object specified in the `destination_directory_object` parameter.

## 74.3 DBMS\_FILE\_TRANSFER Operational Notes

`DBMS_FILE_TRANSFER` supports online backup. You should therefore be careful in copying or transferring a file that is being modified by the database because this can result in an

inconsistent file, and require recovery. To guarantee consistency, bring files offline when the database is in use.

If you want to use DBMS\_FILE\_TRANSFER for performing backups, note that you are implementing self-managed backups, and should therefore put the files in hot backup mode.

## 74.4 Summary of DBMS\_FILE\_TRANSFER Subprograms

This table lists the DBMS\_FILE\_TRANSFER subprograms and briefly describes them.

**Table 74-1 DBMS\_FILE\_TRANSFER Package Subprograms**

| Subprogram                          | Description                                                                                                                                                                                                                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">COPY_FILE Procedure</a> | Reads a file from a source directory and creates a copy of it in a destination directory. The source and destination directories can both be in a local file system, or both be in an Automatic Storage Management (ASM) disk group, or between local file system and ASM with copying in either direction. |
| <a href="#">GET_FILE Procedure</a>  | Contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM                                                                                                                                                                                        |
| <a href="#">PUT_FILE Procedure</a>  | Reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system                                                                                                                                                                                             |

### 74.4.1 COPY\_FILE Procedure

This procedure reads a file from a source directory and creates a copy of it in a destination directory. The source and destination directories can both be in a local file system, or both be in an Automatic Storage Management (ASM) disk group, or between local file system and ASM with copying in either direction.

You can copy any type of file to and from a local file system. However, you can copy only database files (such as datafiles, tempfiles, controlfiles, and so on) to and from an ASM disk group.

The destination file is not closed until the procedure completes successfully.

#### Syntax

```
DBMS_FILE_TRANSFER.COPY_FILE(  
    source_directory_object    IN VARCHAR2,  
    source_file_name           IN VARCHAR2,  
    destination_directory_object IN VARCHAR2,  
    destination_file_name      IN VARCHAR2);
```

#### Parameters

**Table 74-2 COPY\_FILE Procedure Parameters**

| Parameter               | Description                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source_directory_object | The directory object that designates the source directory. The directory object must already exist. (You create directory objects with the CREATE DIRECTORY command). |

**Table 74-2 (Cont.) COPY\_FILE Procedure Parameters**

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>source_file_name</code>             | The name of the file to copy. This file must exist in the source directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>destination_directory_object</code> | The directory object that designates the destination directory. The directory object must already exist. If the destination is ASM, the directory object must designate either a disk group name (for example, <code>+diskgroup1</code> ) or a directory created for alias names. In the case of a directory, the full path to the directory must be specified (for example: <code>+diskgroup1/dbs/control</code> ).                                                                                                                                                                                                                                                                                                                       |
| <code>destination_file_name</code>        | <p>The name to assign to the file in the destination directory. A file with the same name must not exist in the destination directory. If the destination is ASM:</p> <ul style="list-style-type: none"> <li>• The file is given a fully qualified ASM filename and created in the appropriate directory (depending on the database name and file type)</li> <li>• The file type tag assigned to the file is <code>COPY_FILE</code></li> <li>• The value of the <code>destination_file_name</code> argument becomes the file's alias name in the designated destination directory</li> </ul> <p>The file name can be followed by an ASM template name in parentheses. The file is then given the attributes specified by the template.</p> |

### Usage Notes

To run this procedure successfully, the current user must have the following privileges:

- **READ** privilege on the directory object specified in the `source_directory_object` parameter
- **WRITE** privilege on directory object specified in the `destination_directory_object` parameter

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

The `source_file_name` parameter must specify a file that is in the directory specified by the `source_directory_object` parameter before running the procedure, and the `destination_file_name` parameter must specify the new name of the file in the new location specified in the `destination_directory_object` parameter. Relative paths and symbolic links are not allowed in the directory objects for the `source_directory_object` and `destination_directory_object` parameters.

Transferring the file is not transactional. To monitor the progress of a long file copy, query the `V$SESSION_LONGOPS` dynamic performance view.

## Examples

```
SQL> create directory DGROUP as '+diskgroup1/dbs/backup';
```

Directory created.

```
SQL> BEGIN
2   DBMS_FILE_TRANSFER.COPY_FILE('SOURCEDIR','t_xdbtmp.f', 'DGROUP',
                                't_xdbtmp.f');
3 END;
4 /
```

PL/SQL procedure successfully completed.

```
SQL> EXIT
$ASMCMD
ASMCMD> ls
DISKGROUP1/
ASMCMD> cd diskgroup1/dbs/backup
ASMCMD> ls
t_xdbtmp.f => +DISKGROUP1/ORCL/TEMPFILE/COPY_FILE.267.546546525
```

## 74.4.2 GET\_FILE Procedure

This procedure contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM. The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

### Syntax

```
DBMS_FILE_TRANSFER.GET_FILE
    source_directory_object      IN  VARCHAR2,
    source_file_name             IN  VARCHAR2,
    source_database              IN  VARCHAR2,
    destination_directory_object IN  VARCHAR2,
    destination_file_name        IN  VARCHAR2);
```

### Parameters

**Table 74-3 GET\_FILE Procedure Parameters**

| Parameter               | Description                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source_directory_object | The directory object from which the file is copied at the source site. This directory object must exist at the source site.                                                 |
| source_file_name        | The name of the file that is copied in the remote file system. This file must exist in the remote file system in the directory associated with the source directory object. |

**Table 74-3 (Cont.) GET\_FILE Procedure Parameters**

| Parameter                    | Description                                                                                                                                           |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| source_database              | The name of a database link to the remote database where the file is located.                                                                         |
| destination_directory_object | The directory object into which the file is placed at the destination site. This directory object must exist in the local file system.                |
| destination_file_name        | The name of the file copied to the local file system. A file with the same name must not exist in the destination directory in the local file system. |

### Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The connected user at the source database must have read privilege on the directory object specified in the `source_directory_object` parameter.
- The current user at the local database must have write privilege on the directory object specified in the `destination_directory_object` parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

Transferring the file is not transactional. To monitor the progress of a long file transfer, query the `V$SESSION_LONGOPS` dynamic performance view.

### Examples

```
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO "user";
CREATE DIRECTORY DSK_FILES AS '^t_work^';
GRANT WRITE ON DIRECTORY dsk_files TO "user";

-- assumes that dbs2 link has been created and we are connected to the instance.
-- dbs2 could be a loopback or point to another instance.

BEGIN
-- asm file to an os file
-- get an asm file from dbs1.asm/a1 to dbs2.^t_work^/oa5.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'df' , 'a1' , 'dbs1', 'dsk_files' , 'oa5.dat' );

-- os file to an os file
-- get an os file from dbs1.^t_work^/a2.dat to dbs2.^t_work^/a2back.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'dsk_files' , 'a2.dat' , 'dbs1', 'dsk_files' ,
'a2back.dat' );

END ;
/
```

## 74.4.3 PUT\_FILE Procedure

This procedure reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system.

The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

### Syntax

```
DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object    IN  VARCHAR2,
    source_file_name          IN  VARCHAR2,
    destination_directory_object IN  VARCHAR2,
    destination_file_name      IN  VARCHAR2,
    destination_database       IN  VARCHAR2);
```

### Parameters

**Table 74-4 PUT\_FILE Procedure Parameters**

| Parameter                    | Description                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| source_directory_object      | The directory object from which the file is copied at the local source site. This directory object must exist at the source site.                                           |
| source_file_name             | The name of the file that is copied from the local file system. This file must exist in the local file system in the directory associated with the source directory object. |
| destination_directory_object | The directory object into which the file is placed at the destination site. This directory object must exist in the remote file system.                                     |
| destination_file_name        | The name of the file placed in the remote file system. A file with the same name must not exist in the destination directory in the remote file system.                     |
| destination_database         | The name of a database link to the remote database to which the file is copied.                                                                                             |

### Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The current user at the local database must have read privilege on the directory object specified in the `source_directory_object` parameter.
- The connected user at the destination database must have write privilege to the directory object specified in the `destination_directory_object` parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

Transferring the file is not transactional. To monitor the progress of a long file transfer, query the V\$SESSION\_LONGOPS dynamic performance view.

### Examples

```
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO "user";
CREATE OR REPLACE DIRECTORY ft1 AS '+datafile/ft1' ;
GRANT READ,WRITE ON DIRECTORY ft1 TO "user";
CREATE OR REPLACE DIRECTORY ft1_1 AS '+datafile/ft1/ft1_1' ;

CONNECT user;
Enter password: password

-- - put a1.dat to a4.dat (using dbs2 dblink)
-- - level 2 sub dir to parent dir
-- - user has read privs on ft1_1 at dbs1 and write on df in dbs2
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE ( 'ft1_1' , 'a2.dat' , 'df' , 'a4.dat' ,
                                'dbs2' ) ;
END ;
```

# DBMS\_FLASHBACK

Using `DBMS_FLASHBACK`, you can flash back to a version of the database at a specified time or a specified system change number (SCN).

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Types](#)
- [Exceptions](#)
- [Operational Notes](#)
- [Examples](#)
- [Summary of DBMS\\_FLASHBACK Subprograms](#)

## See Also:

For detailed information about `DBMS_FLASHBACK`:

- *Oracle Database Development Guide*
- *Oracle Database SQL Language Reference*.

## 75.1 DBMS\_FLASHBACK Overview

`DBMS_FLASHBACK` provides an interface for the user to view the database at a particular time in the past, with the additional capacity provided by transaction back out features that allow for selective removal of the effects of individual transactions. This is different from a flashback database which moves the database back in time.

When `DBMS_FLASHBACK` is enabled, the user session uses the Flashback version of the database, and applications can execute against the Flashback version of the database.

You may want to use `DBMS_FLASHBACK` for the following reasons:

- Self-service repair: If you accidentally delete rows from a table, you can recover the deleted rows.
- Packaged applications such as email and voicemail: You can use Flashback to restore deleted email by re-inserting the deleted message into the current message box.
- Decision support system (DSS) and online analytical processing (OLAP) applications: You can perform data analysis or data modeling to track seasonal demand.

## 75.2 DBMS\_FLASHBACK Security Model

To use the `DBMS_FLASHBACK` package, you must have the `EXECUTE` privilege on it.

## 75.3 DBMS\_FLASHBACK Types

The following table describes the types used by DBMS\_FLASHBACK.

**Table 75-1 DBMS\_FLASHBACK**

| Type         | Description                                                          |
|--------------|----------------------------------------------------------------------|
| TXNAME_ARRAY | Creates a VARRAY for holding Transaction Names or Identifiers (XIDs) |

## 75.4 DBMS\_FLASHBACK Exceptions

DBMS\_FLASHBACK creates the following error messages.

**Table 75-2 DBMS\_FLASHBACK Error Messages**

| Error     | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| ORA-08180 | Time specified is too old                                                  |
| ORA-08181 | Invalid system change number specified                                     |
| ORA-08182 | User cannot begin read-only or serializable transactions in Flashback mode |
| ORA-08183 | User cannot enable Flashback within an uncommitted transaction             |
| ORA-08184 | User cannot enable Flashback within another Flashback session              |
| ORA-08185 | SYS cannot enable Flashback mode                                           |

## 75.5 DBMS\_FLASHBACK Operational Notes

DBMS\_FLASHBACK is automatically turned off when the session ends, either by disconnection or by starting another connection.

PL/SQL cursors opened in Flashback mode return rows as of the flashback time or SCN. Different concurrent sessions (connections) in the database can perform Flashback to different wall-clock times or SCNs. DML and DDL operations and distributed operations are not allowed while a session is running in Flashback mode. You can use PL/SQL cursors opened before disabling Flashback to perform DML.

Under Automatic Undo Management (AUM) mode, you can use retention control to control how far back in time to go for the version of the database you need. If you need to perform a Flashback over a 24-hour period, the DBA must set the `undo_retention` parameter to 24 hours. This way, the system retains enough undo information to regenerate the older versions of the data.

You can set the `RETENTION GUARANTEE` clause for the undo tablespace to ensure that unexpired undo is not discarded. `UNDO_RETENTION` is not in itself a guarantee because, if the system is under space pressure, unexpired undo may be overwritten with freshly generated undo. In such cases, `RETENTION GUARANTEE` prevents this. For more information, see the *Oracle Database Administrator's Guide*.

In a Flashback-enabled session, SYSDATE is not affected; it continues to provide the current time.

DBMS\_FLASHBACK can be used within logon triggers to enable Flashback without changing the application code.

## 75.6 DBMS\_FLASHBACK Examples

The following example illustrates how Flashback can be used when the deletion of a senior employee triggers the deletion of all the personnel reporting to him. Using the Flashback feature, you can recover and re-insert the missing employees.

```
DROP TABLE employee;
DROP TABLE keep_scn;

REM -- Keep_scn is a temporary table to store scns that we are interested in

CREATE TABLE keep_scn (scn number);
SET ECHO ON
CREATE TABLE employee (
  employee_no    number(5) PRIMARY KEY,
  employee_name  varchar2(20),
  employee_mgr   number(5)
    CONSTRAINT mgr_fkey REFERENCES EMPLOYEE ON DELETE CASCADE,
  salary         number,
  hiredate       date
);

REM -- Populate the company with employees
INSERT INTO employee VALUES (1, 'John Doe', null, 1000000, '5-jul-81');
INSERT INTO employee VALUES (10, 'Joe Johnson', 1, 500000, '12-aug-84');
INSERT INTO employee VALUES (20, 'Susie Tiger', 10, 250000, '13-dec-90');
INSERT INTO employee VALUES (100, 'Scott Tiger', 20, 200000, '3-feb-86');
INSERT INTO employee VALUES (200, 'Charles Smith', 100, 150000, '22-mar-88');
INSERT INTO employee VALUES (210, 'Jane Johnson', 100, 100000, '11-apr-87');
INSERT INTO employee VALUES (220, 'Nancy Doe', 100, 100000, '18-sep-93');
INSERT INTO employee VALUES (300, 'Gary Smith', 210, 75000, '4-nov-96');
INSERT INTO employee VALUES (310, 'Bob Smith', 210, 65000, '3-may-95');
COMMIT;

REM -- Show the entire org
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;

REM -- Sleep for a short time (approximately 10 to 20 seconds) to avoid
REM -- querying close to table creation

EXECUTE DBMS_LOCK.SLEEP(10);

REM -- Store this snapshot for later access through Flashback
DECLARE
I NUMBER;
BEGIN
I := DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER;
INSERT INTO keep_scn VALUES (I);
COMMIT;
END;
/
```

```
REM -- Scott decides to retire but the transaction is done incorrectly
DELETE FROM EMPLOYEE WHERE employee_name = 'Scott Tiger';
COMMIT;

REM -- notice that all of scott's employees are gone
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM EMPLOYEE
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;

REM -- Flashback to see Scott's organization
DECLARE
    restore_scn number;
BEGIN
    SELECT scn INTO restore_scn FROM keep_scn;
    DBMS_FLASHBACK.ENABLE_AT_SYSTEM_CHANGE_NUMBER (restore_scn);
END;
/

REM -- Show Scott's org.
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no =
    (SELECT employee_no FROM employee WHERE employee_name = 'Scott Tiger')
ORDER BY LEVEL;

REM -- Restore scott's organization.
DECLARE
    scotts_emp NUMBER;
    scotts_mgr NUMBER;
    CURSOR c1 IS
        SELECT employee_no, employee_name, employee_mgr, salary, hiredate
        FROM employee
        CONNECT BY PRIOR employee_no = employee_mgr
        START WITH employee_no =
            (SELECT employee_no FROM employee WHERE employee_name = 'Scott Tiger');
    c1_rec c1 % ROWTYPE;
BEGIN
    SELECT employee_no, employee_mgr INTO scotts_emp, scotts_mgr FROM employee
    WHERE employee_name = 'Scott Tiger';
    /* Open c1 in flashback mode */
    OPEN c1;
    /* Disable Flashback */
    DBMS_FLASHBACK.DISABLE;
    LOOP
        FETCH c1 INTO c1_rec;
        EXIT WHEN c1%NOTFOUND;
        /*
            Note that all the DML operations inside the loop are performed
            with Flashback disabled
        */
        IF (c1_rec.employee_mgr = scotts_emp) then
            INSERT INTO employee VALUES (c1_rec.employee_no,
                c1_rec.employee_name,
                scotts_mgr,
                c1_rec.salary,
                c1_rec.hiredate);
        ELSE
            IF (c1_rec.employee_no != scotts_emp) THEN
```

```

INSERT INTO employee VALUES (c1_rec.employee_no,
                              c1_rec.employee_name,
                              c1_rec.employee_mgr,
                              c1_rec.salary,
                              c1_rec.hiredate);
END IF;
END IF;
END LOOP;
END;
/

REM -- Show the restored organization.
select lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;
```

## 75.7 Summary of DBMS\_FLASHBACK Subprograms

This table lists the DBMS\_FLASHBACK subprograms and briefly describes them.

**Table 75-3 DBMS\_FLASHBACK Package Subprograms**

| Subprogram                                               | Description                                                                                                                                                                                                                                |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DISABLE Procedure</a>                        | Disables the Flashback mode for the entire session                                                                                                                                                                                         |
| <a href="#">ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure</a> | Enables Flashback for the entire session. Takes an SCN as an Oracle number and sets the session snapshot to the specified number. Inside the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN |
| <a href="#">ENABLE_AT_TIME Procedure</a>                 | Enables Flashback for the entire session. The snapshot time is set to the SCN that most closely matches the time specified in <code>query_time</code>                                                                                      |
| <a href="#">GET_SYSTEM_CHANGE_NUMBER Function</a>        | Returns the current SCN as an Oracle number. You can use the SCN to store specific snapshots                                                                                                                                               |
| <a href="#">TRANSACTION_BACKOUT Procedures</a>           | Provides the mechanism to back out a transaction                                                                                                                                                                                           |

### 75.7.1 DISABLE Procedure

This procedure disables the Flashback mode for the entire session.

#### Syntax

```
DBMS_FLASHBACK.DISABLE;
```

#### Examples

The following example queries the salary of an employee, Joe, on August 30, 2000:

```
EXECUTE dbms_flashback.enable_at_time('30-AUG-2000');
SELECT salary FROM emp where name = 'Joe'
EXECUTE dbms_flashback.disable;
```

## 75.7.2 ENABLE\_AT\_SYSTEM\_CHANGE\_NUMBER Procedure

This procedure takes an SCN as an input parameter and sets the session snapshot to the specified number.

In the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN. It enables Flashback for the entire session.

### Syntax

```
DBMS_FLASHBACK.ENABLE_AT_SYSTEM_CHANGE_NUMBER (
    query_scn IN NUMBER);
```

### Parameters

**Table 75-4 ENABLE\_AT\_SYSTEM\_CHANGE\_NUMBER Procedure Parameters**

| Parameter | Description                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| query_scn | The system change number (SCN), a version number for the database that is incremented on every transaction commit. |

## 75.7.3 ENABLE\_AT\_TIME Procedure

This procedure enables Flashback for the entire session.

The snapshot time is set to the SCN that most closely matches the time specified in query\_time. It enables Flashback for the entire session.

### Syntax

```
DBMS_FLASHBACK.ENABLE_AT_TIME (
    query_time IN TIMESTAMP);
```

## Parameters

**Table 75-5** ENABLE\_AT\_TIME Procedure Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| query_time | <p>This is an input parameter of type <code>TIMESTAMP</code>. A time stamp can be specified in the following ways:</p> <ul style="list-style-type: none"><li>Using the <code>TIMESTAMP</code> constructor</li></ul> <pre>EXECUTE DBMS_FLASHBACK.ENABLE_AT_TIME (TIMESTAMP<br/>'2001-01-09 12:31:00').</pre> <p>Use the Globalization Support (NLS) format and supply a string. The format depends on the Globalization Support settings.</p> <ul style="list-style-type: none"><li>Using the <code>TO_TIMESTAMP</code> function:</li></ul> <pre>EXECUTE<br/>DBMS_FLASHBACK.ENABLE_AT_TIME (TO_TIMESTAMP ('12-02-2001<br/>14:35:00', 'DD-MM-YYYY HH24:MI:SS'))</pre> <p>You provide the format you want to use. This example shows the <code>TO_TIMESTAMP</code> function for February 12, 2001, 2:35 PM.</p> <ul style="list-style-type: none"><li>If the time is omitted from query time, it defaults to the beginning of the day, that is, 12:00 A.M.</li><li>Note that if the query time contains a time zone, the time zone information is truncated.</li></ul> |

## 75.7.4 GET\_SYSTEM\_CHANGE\_NUMBER Function

This function returns the current SCN as an Oracle number datatype. You can obtain the current change number and store it for later use. This helps you retain specific snapshots.

### Syntax

```
DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER  
RETURN NUMBER;
```

## 75.7.5 TRANSACTION\_BACKOUT Procedures

This procedure provides a mechanism to back out a set of transactions. The user can call these procedures with either transaction names or transaction identifiers (XIDS).

The procedure analyzes the transactional dependencies, perform DMLs and generates an extensive report on the operation performed by the subprogram. This procedure does not commit the DMLs performed as part of transaction back out. However it holds all the required locks on rows and tables in the right form, so that no other dependencies can enter the system. To make the changes permanent you must explicitly commit the transaction.

A report is generated in the system tables `DBA_FLASHBACK_TRANSACTION_STATE` and `DBA_FLASHBACK_TRANSACTION_REPORT`.

### Syntax

```
DBMS_FLASHBACK.TRANSACTION_BACKOUT  
numtxns          NUMBER,  
xids              XID_ARRAY,  
options           NUMBER default NOCASCADE,
```

```

timeHint          TIMESTAMP default MINTIME);

DBMS_FLASHBACK.TRANSACTION_BACKOUT
  numtxns          NUMBER,
  xids              XID_ARRAY,
  options           NUMBER default NOCASCADE,
  scnHint           TIMESTAMP default 0 );

DBMS_FLASHBACK.TRANSACTION_BACKOUT
  numtxns          NUMBER,
  txnnames          TXNAME_ARRAY,
  options           NUMBER default NOCASCADE,
  timehint          TIMESTAMP MINTIME );

DBMS_FLASHBACK.TRANSACTION_BACKOUT
  numtxns          NUMBER,
  txnNames          TXNAME_ARRAY,
  options           NUMBER default NOCASCADE,
  scnHint           NUMBER 0);

```

## Parameters

**Table 75-6 TRANSACTION\_BACKOUT Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| numtxns   | Number of transactions passed as input                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| xids      | List of transaction IDs in the form of an array                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| txnnames  | List of transaction names in the form of an array                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| options   | Back out dependent transactions: <ul style="list-style-type: none"> <li>• NOCASCADE - No dependency is expected. If a dependency is found, this raises an error, with the first dependent transaction provided in the report.</li> <li>• NOCASCADE_FORCE - The user forcibly backs out the given transactions without considering the dependent transactions. The RDBMS executes the UNDO SQL for the given transactions in reverse order of their commit times. If no constraints break, and the result is satisfactory, the user can either COMMIT the changes or else ROLL BACK.</li> <li>• NONCONFLICT_ONLY - This option lets the user back out the changes to the nonconflicting rows of the given transactions. Note that a transaction dependency can happen due to a row conflict through either WAW or primary/unique key constraints. If the user chooses to back out only the nonconflicting rows, this does not cause any problem with database consistency, although transaction atomicity is lost. As this is a recovery operation, the user can correct the data.</li> <li>• CASCADE - This completely removes the given transactions including their dependents in a post order fashion (reverse order of commit times).</li> </ul> |
| timehint  | Time hint on the start of the transaction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| scnhint   | SCN hint on the start of the transaction                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Usage Notes

### Note:

For information about restrictions in using `TRANSACTION_BACKOUT`, see "Using Flashback Transaction" in the *Oracle Database Development Guide*.

- If transaction name is used, a time hint must be provided. The time hint should be a time before the start of all the given transactions to back out.
- If the SCN hint is provided, it must be before the start of the earliest transaction in the specified input set, or this raises an error and terminates. If it is not provided and the transaction has committed within undo retention, the database system is able to determine the start time.

# DBMS\_FLASHBACK\_ARCHIVE

The `DBMS_FLASHBACK_ARCHIVE` package contains procedures for performing various flashback archive tasks.

These include:

- Disassociation and reassociation of a Flashback Archive enabled table from/with its underlying Flashback Time Travel
- Tamper-proofing the tables of an application
- Importing of user history

## **Caution:**

Importing user-generated history can lead to inaccurate, or unreliable results. This procedure should only be used after consulting with Oracle Support.

- Enabling and disabling of session-level support for valid-time

## **See Also:**

*Oracle Database Development Guide* for more information about Using Flashback Time Travel

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_FLASHBACK\\_ARCHIVE Subprograms](#)

## 76.1 DBMS\_FLASHBACK\_ARCHIVE Overview

Flashback Time Travel provides strict protection on the internal history tables that it creates and maintains for users.

### Caution:

The `DBMS_FLASHBACK_ARCHIVE` package does not support migration between databases. It allows you to move Flashback Time Travel history within the same database only, and not outside it. This package does not allow you to move Flashback Time Travel table data. It allows you to import customer history only and not Flashback Time Travel history.

The read-only semantics prohibit users, including a DBA, from doing updates, deletes, and inserts on the Flashback Time Travel internal history tables. Users are also prevented from issuing any DDL statements on these tables. This strict security enforcement helps meet the requirements of applications in regulatory / compliance environments. Flashback Time Travel supports most common DDL statements, including those that alter the table definition or incur data movement. However, some DDL statements are not supported on Flashback Archive enabled tables. Since most application schemas are modified during application software upgrades, the ability to perform DDL operations on tracked tables is critical.

To support schema evolution during application upgrades and other table maintenance tasks that require use of DDL statements not supported by Flashback Time Travel, the `DBMS_FLASHBACK_ARCHIVE` package provides a set of simple-to-use PL/SQL procedures:

- To disassociate a Flashback Archive enabled base table from the underlying Flashback Time Travel
- To reassociate a temporarily disassociated base table with its underlying Flashback Time Travel

After a user has disassociated the base table from its Flashback Archive, it's possible to issue any DDL statements on the base table or the history tables in the Flashback Archive. Having finished with the schema changes, the user can then reassociate the base table with its Flashback Archive so that Flashback Time Travel protection is in operation and automatic tracking and archiving is resumed.

## 76.2 DBMS\_FLASHBACK\_ARCHIVE Security Model

Users need the `FLASHBACK_ARCHIVE_ADMINISTER` privilege to import user-generated history, to set context level, and to tamper-proof tables. After a table is disassociated, users can perform DDL and DML statements on the table if they have the necessary privileges. Enabling and disabling session-level Valid Time Temporal flashback needs no additional privileges.

## 76.3 DBMS\_FLASHBACK\_ARCHIVE Constants

The `DBMS_FLASHBACK_ARCHIVE` package uses the constants shown in the following table.

**Table 76-1 DBMS\_FLASHBACK\_ARCHIVE Constants**

| Constant | Type           | Value | Description                         |
|----------|----------------|-------|-------------------------------------|
| NODROP   | BINARY_INTEGER | 1     | Do not drop temporary history table |
| NOCOMMIT | BINARY_INTEGER | 2     | Do not commit transaction           |
| NODELETE | BINARY_INTEGER | 4     | Do not delete data in history table |

## 76.4 Summary of DBMS\_FLASHBACK\_ARCHIVE Subprograms

This table lists the DBMS\_FLASHBACK\_ARCHIVE subprograms and briefly describes them.

**Table 76-2 DBMS\_FLASHBACK\_ARCHIVE Package Subprograms**

| Subprogram                                              | Description                                                                                                     |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_TABLE_TO_APPLICATION Procedure</a>      | Takes an application name and adds a table to the application as a security table                               |
| <a href="#">CREATE_TEMP_HISTORY_TABLE Procedure</a>     | Creates a table called TEMP_HISTORY with the correct definition in schema                                       |
| <a href="#">DISABLE_APPLICATION Procedure</a>           | Takes an application name and marks a table in it as a security table                                           |
| <a href="#">DISABLE_ASOF_VALID_TIME Procedure</a>       | Disables session level valid-time flashback                                                                     |
| <a href="#">DISASSOCIATE_FBA Procedure</a>              | Disassociates the given table from the Flashback Time Travel                                                    |
| <a href="#">DROP_APPLICATION Procedure</a>              | Takes an application name and removes it from the list of applications                                          |
| <a href="#">ENABLE_APPLICATION Procedure</a>            | Takes an application name and enables Flashback Time Travel on all the security tables for this application     |
| <a href="#">ENABLE_AT_VALID_TIME Procedure</a>          | Enables session level valid time flashback                                                                      |
| <a href="#">EXTEND_MAPPINGS Procedure</a>               | Extends time mappings to times in the past                                                                      |
| <a href="#">GET_SYS_CONTEXT Function</a>                | Gets the context previously selected by the <a href="#">SET_CONTEXT_LEVEL Procedure</a>                         |
| <a href="#">IMPORT_HISTORY Procedure</a>                | Imports history from a table called TEMP_HISTORY in the given schema.                                           |
| <a href="#">LOCK_DOWN_APPLICATION Procedure</a>         | Takes an application name and makes all the security tables read-only. The group called SYSTEM cannot be locked |
| <a href="#">PURGE_CONTEXT Procedure</a>                 | Purges the context to be saved selected by the <a href="#">SET_CONTEXT_LEVEL Procedure</a>                      |
| <a href="#">REASSOCIATE_FBA Procedure</a>               | Reassociates the given table with the Flashback Time Travel                                                     |
| <a href="#">REGISTER_APPLICATION Procedure</a>          | Takes an application name and optionally a Time Travel, and registers an application for database hardening     |
| <a href="#">REMOVE_TABLE_FROM_APPLICATION Procedure</a> | Takes an application name and marks a table in it as no longer being a security table                           |
| <a href="#">SET_CONTEXT_LEVEL Procedure</a>             | Defines how much of the user context is to be saved                                                             |

## 76.4.1 ADD\_TABLE\_TO\_APPLICATION Procedure

This procedure takes an application name and adds a table to the application as a security table. If the application is enabled for Flashback Time Travel, then this table will also be enabled for Flashback Time Travel.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.ADD_TABLE_TO_APPLICATION (
    application_name    IN    VARCHAR2,
    table_name          IN    VARCHAR2,
    schema_name         IN    VARCHAR2 := NULL);
```

### Parameters

**Table 76-3 ADD\_TABLE\_TO\_APPLICATION Procedure Parameters**

| Parameter        | Description                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------|
| application_name | Name of the application for which a table has been added as a security table                                 |
| table_name       | Name of the table to add as a security table for the given application                                       |
| schema_name      | Name of the schema containing the desired table. If no schema name is specified, the current schema is used. |

## 76.4.2 CREATE\_TEMP\_HISTORY\_TABLE Procedure

This procedure creates a table called `TEMP_HISTORY` with the correct definition in schema.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.CREATE_TEMP_HISTORY_TABLE (
    owner_name1    IN    VARCHAR2,
    table_name1    IN    VARCHAR2);
```

### Parameters

**Table 76-4 CREATE\_TEMP\_HISTORY\_TABLE Procedure Parameters**

| Parameter   | Description                                       |
|-------------|---------------------------------------------------|
| owner_name1 | Schema of the Flashback Time Travel-enabled table |
| table_name1 | Name of the Flashback Time Travel-enabled table   |

## 76.4.3 DISABLE\_APPLICATION Procedure

This procedure takes an application name and disables Flashback Time Travel on all of its security tables.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISABLE_APPLICATION (
    application_name    IN    VARCHAR2);
```

## Parameters

**Table 76-5 DISABLE\_APPLICATION Procedure Parameters**

| Parameter        | Description                                                                              |
|------------------|------------------------------------------------------------------------------------------|
| application_name | Name of the application whose security tables will be disabled for Flashback Time Travel |

## 76.4.4 DISABLE\_ASOF\_VALID\_TIME Procedure

This procedure disables session level valid-time flashback.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISABLE_ASOF_VALID_TIME;
```

## 76.4.5 DISASSOCIATE\_FBA Procedure

This procedure disassociates the given table from the Flashback Time Travel.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISASSOCIATE_FBA (
    owner_name      IN   VARCHAR2,
    table_name      IN   VARCHAR2);
```

## Parameters

**Table 76-6 DISASSOCIATE\_FBA Procedure Parameters**

| Parameter  | Description                                            |
|------------|--------------------------------------------------------|
| owner_name | Schema of the Flashback Time Travel enabled base table |
| table_name | Name of the Flashback Time Travel enabled base table   |

## Exceptions

**Table 76-7 DISASSOCIATE\_FBA Procedure Exceptions**

| Exception | Description                                             |
|-----------|---------------------------------------------------------|
| ORA-55602 | User table is not enabled for Flashback Time Travel     |
| ORA-55634 | Cannot acquire the lock on the table for disassociation |

## 76.4.6 DROP\_APPLICATION Procedure

This procedure takes an application name and removes it from the list of applications. As part of this procedure, Flashback Time Travel will be disabled on all security-enabled tables and all history data will be lost. The group called `SYSTEM` cannot be dropped.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.DROP_APPLICATION (
    application_name      IN   VARCHAR2);
```

### Parameters

**Table 76-8 DROP\_APPLICATION Procedure Parameters**

| Parameter        | Description                                                                  |
|------------------|------------------------------------------------------------------------------|
| application_name | Name of the application for which a table has been added as a security table |

## 76.4.7 ENABLE\_APPLICATION Procedure

This procedure takes an application name and enables Flashback Time Travel on all the security tables for this application. Once an application is enabled, every change to an Flashback Time Travel enabled table will be tracked.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.ENABLE_APPLICATION (
    application_name      IN   VARCHAR2);
```

### Parameters

**Table 76-9 ENABLE\_APPLICATION Procedure Parameters**

| Parameter        | Description                                                                                  |
|------------------|----------------------------------------------------------------------------------------------|
| application_name | Name of the application for which to enable Flashback Time Travel on all its security tables |

## 76.4.8 ENABLE\_AT\_VALID\_TIME Procedure

This procedure enables session level valid time flashback.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.ENABLE_AT_VALID_TIME (
    level      IN   VARCHAR2,
    query_time IN   TIMESTAMP DEFAULT SYSTIMESTAMP);
```

## Parameters

**Table 76-10 ENABLE\_AT\_VALID\_TIME Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| level      | Options: <ul style="list-style-type: none"> <li>All - Sets the visibility of temporal data to the full table, which is the default temporal table visibility</li> <li>CURRENT - Sets the visibility of temporal data to currently valid data within the valid time period at the session level</li> <li>ASOF - Sets the visibility of temporal data to data valid as of the given time as defined by the timestamp</li> </ul> |
| query_time | Used only if level is ASOF. Data which is valid at this query_time will only be shown.                                                                                                                                                                                                                                                                                                                                        |

## 76.4.9 EXTEND\_MAPPINGS Procedure

This procedure extends time mappings to times in the past.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.EXTEND_MAPPINGS;
```

## 76.4.10 GET\_SYS\_CONTEXT Function

This function gets the context previously selected by the SET\_CONTEXT\_LEVEL Procedure.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.GET_SYS_CONTEXT (
    xid          IN    RAW,
    namespace    IN    VARCHAR2,
    parameter    IN    VARCHAR2)
RETURN VARCHAR2;
```

## Parameters

**Table 76-11 GET\_SYS\_CONTEXT Function Parameters**

| Parameter | Description                                                                                  |
|-----------|----------------------------------------------------------------------------------------------|
| xid       | Transaction identifier is an opaque handle to a transaction obtained from the versions query |
| namespace | Namespace                                                                                    |
| parameter | If undefined, the subprogram returns NULL                                                    |

### Related Topics

This procedure defines how much of the user context is to be saved.

## 76.4.11 IMPORT\_HISTORY Procedure

This procedure is called after invoking the `CREATE_TEMP_HISTORY_TABLE` procedure, and after the `TEMP_HISTORY` table is populated with user-generated history data

### Caution:

Importing user-generated history can lead to inaccurate, or unreliable results. This procedure should only be used after consulting with Oracle Support.

The `DBMS_FLASHBACK_ARCHIVE` package does not support migration between databases. It allows you to move Flashback Time Travel history within the same database only, and not outside it. This package does not allow you to move Flashback Time Travel table data. It allows you to import customer history only and not Flashback Time Travel history.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.IMPORT_HISTORY (
  owner_name1      IN   VARCHAR2,
  table_name1      IN   VARCHAR2
  temp_history_name IN   VARCHAR2 DEFAULT 'TEMP_HISTORY',
  options          IN   BINARY_INTEGER DEFAULT 0);
```

### Parameters

**Table 76-12** `IMPORT_HISTORY` Procedure Parameters

| Parameter                      | Description                                                                                                                                                                                               |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>owner_name1</code>       | Schema of the Flashback Time Travel-enabled table                                                                                                                                                         |
| <code>table_name1</code>       | Name of the Flashback Time Travel-enabled table                                                                                                                                                           |
| <code>temp_history_name</code> | Optional temporary history table from which we import history data                                                                                                                                        |
| <code>options</code>           | One (or a combination) of constants ( <code>NODROP</code> , <code>NOCOMMIT</code> , and <code>NODELETE</code> ) to specify if we want to drop, commit changes of, or truncate the temporary history table |

### Usage Notes

The database function `TIMESTAMP_TO_SCN` can be used to convert times to SCN when populating the temporary history table.

### Related Topics

- [CREATE\\_TEMP\\_HISTORY\\_TABLE Procedure](#)  
This procedure creates a table called `TEMP_HISTORY` with the correct definition in schema.

## 76.4.12 LOCK\_DOWN\_APPLICATION Procedure

This procedure takes an application name and makes all the security tables read-only. The group called `SYSTEM` cannot be locked.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.LOCK_DOWN_APPLICATION (
    application_name      IN   VARCHAR2);
```

### Parameters

**Table 76-13 LOCK\_DOWN\_APPLICATION Procedure Parameters**

| Parameter                     | Description                                                                  |
|-------------------------------|------------------------------------------------------------------------------|
| <code>application_name</code> | Name of the application for which a table has been added as a security table |

## 76.4.13 PURGE\_CONTEXT Procedure

This procedure purges the context to be saved selected by the `SET_CONTEXT_LEVEL` Procedure.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.PURGE_CONTEXT;
```

### Related Topics

- [SET\\_CONTEXT\\_LEVEL Procedure](#)  
This procedure defines how much of the user context is to be saved.

## 76.4.14 REASSOCIATE\_FBA Procedure

This procedure reassociates the given table with the Flashback Time Travel.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA (
    owner_name      VARCHAR2,
    table_name      VARCHAR2);
```

### Parameters

**Table 76-14 REASSOCIATE\_FBA Procedure Parameters**

| Parameter               | Description                                            |
|-------------------------|--------------------------------------------------------|
| <code>owner_name</code> | Schema of the Flashback Time Travel enabled base table |
| <code>table_name</code> | Name of the Flashback Time Travel enabled base table   |

## Exceptions

**Table 76-15 REASSOCIATE\_FBA Procedure Exceptions**

| Parameter | Description                                         |
|-----------|-----------------------------------------------------|
| ORA-55602 | User table is not enabled for Flashback Time Travel |
| ORA-55636 | Table definition validation failed                  |

## Usage Notes

- The procedure will signal an error if the base table and the history table do not have identical data definitions. For example, when columns are added or table is split, the resulting base table and history table need to have the same schema.
- The Flashback Time Travel internal history table schema has some row versions metadata columns. The procedure will signal an error if any metadata column is dropped by users.

## 76.4.15 REGISTER\_APPLICATION Procedure

This procedure takes an application name and optionally a Flashback Archive, and registers an application for database hardening.

When database hardening is enabled, then all the security tables for that application are enabled for Flashback Archive using the given Flashback Archive. If no Flashback Archive is specified, the default Flashback Archive is used.

### See Also:

Using Flashback Time Travel in *Oracle Database Development Guide* regarding database hardening

## Syntax

```
DBMS_FLASHBACK_ARCHIVE.REGISTER_APPLICATION (
    application_name      IN   VARCHAR2,
    flashback_archive_name IN   VARCHAR2 := NULL);
```

## Parameters

**Table 76-16 REGISTER\_APPLICATION Procedure Parameters**

| Parameter              | Description                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| application_name       | Name of the application which is being registered. The application <b>SYSTEM</b> is already registered when the package is created and is populated with list of tables needed for database hardening. |
| flashback_archive_name | Name of the Flashback Archive in which the historical data for the security tables for given application is stored. If no Flashback Archive is specified, the default Flashback Archive is used.       |

## 76.4.16 REMOVE\_TABLE\_FROM\_APPLICATION Procedure

This procedure takes an application name and marks a table in it as no longer being a security table.

If the application is already enabled for Flashback Archive, Flashback Archive will be disabled for this table.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.REMOVE_TABLE_TO_APPLICATION (
    application_name    IN    VARCHAR2,
    table_name          IN    VARCHAR2,
    schema_name         IN    VARCHAR2 := NULL);
```

### Parameters

**Table 76-17 REMOVE\_TABLE\_FROM\_APPLICATION Procedure Parameters**

| Parameter        | Description                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------|
| application_name | Name of the application for which a table is being removed from the list of security tables                  |
| table_name       | Name of the table to mark as being no longer a security table for the given application                      |
| schema_name      | Name of the schema containing the desired table. If no schema name is specified, the current schema is used. |

## 76.4.17 SET\_CONTEXT\_LEVEL Procedure

This procedure defines how much of the user context is to be saved.

### Syntax

```
DBMS_FLASHBACK_ARCHIVE.SET_CONTEXT_LEVEL (
    level    VARCHAR2);
```

### Parameters

**Table 76-18 SET\_CONTEXT\_LEVEL Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| level     | Depending on how much of the user context needs to be saved: <ul style="list-style-type: none"> <li>• ALL - the entire SYS_CONTEXT</li> <li>• TYPICAL - the user ID, global user ID and the hostname</li> <li>• NONE - nothing</li> </ul> |

# DBMS\_FREQUENT\_ITEMSET

The DBMS\_FREQUENT\_ITEMSET package enables frequent itemset counting. The two functions are identical except in the input cursor format difference.

This chapter contains the following topics:

- [Summary of DBMS\\_FREQUENT\\_ITEMSET Subprograms](#)

## 77.1 Summary of DBMS\_FREQUENT\_ITEMSET Subprograms

The DBMS\_FREQUENT\_ITEMSET package includes the FI\_HORIZONTAL function and FI\_TRANSACTIONAL function subprograms.

**Table 77-1 DBMS\_FREQUENT\_ITEMSET Package Subprograms**

| Subprogram                                | Description                                                                                                                                                                                                      |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">FI_HORIZONTAL Function</a>    | Counts all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded    |
| <a href="#">FI_TRANSACTIONAL Function</a> | Counts all frequent itemsets given a cursor for input data which is in 'TRANSACTIONAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded |

### 77.1.1 FI\_HORIZONTAL Function

The purpose of this table function is to count all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total transactions counted.

In 'HORIZONTAL' row format, each row contains all of the item ids for a single transaction. Since all of the items come together, no transaction id is necessary.

The benefit of this table function is that if an application already has data in horizontal format, the database can skip the step of transforming rows that are in transactional format into horizontal format.

#### Syntax

```
DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL (
    tranx_cursor      IN      SYSREFCURSOR,
    support_threshold  IN      NUMBER,
    itemset_length_min IN      NUMBER,
    itemset_length_max IN      NUMBER,
    including_items    IN      SYS_REFCURSOR DEFAULT NULL,
    excluding_items    IN      SYS_REFCURSOR DEFAULT NULL)
RETURN TABLE OF ROW (
    itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
```

```

support      NUMBER,
length       NUMBER,
total_tranx  NUMBER);

```

## Parameters

**Table 77-2 FI\_HORIZONTAL Function Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tranx_cursor       | The cursor parameter that the user will supply when calling the function. There is no limits on the number of returning columns. Each column of cursor represents an item. All columns of the cursor must be of the same datatype. The item id must be number or character type (for example, VARCHAR2(n)). |
| support_threshold  | A fraction number of total transaction count. An itemset is termed "frequent" if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a NUMBER.                                                                               |
| itemset_length_min | The minimum length for interested frequent itemset. The parameter must be a NUMBER between 1 and 20, inclusive.                                                                                                                                                                                             |
| itemset_length_max | The maximum length for interested frequent itemset. This parameter must be a NUMBER between 1 and 20, inclusive, and must not be less than itemset_length_min.                                                                                                                                              |
| including_items    | A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that are returned. The default is NULL.                                                                                                                                                |
| excluding_items    | A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that are returned. The default is NULL.                                                                                                                                                           |

## Return Values

**Table 77-3 FI\_HORIZONTAL Return Values**

| Parameter   | Description                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| support     | The number of transactions in which a frequent itemset occurs. This will be returned as a NUMBER.                                                                    |
| itemset     | A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor. |
| length      | Number of items in a frequent itemset. This will be returned as a NUMBER.                                                                                            |
| total_tranx | The total transaction count. This will be returned as a NUMBER.                                                                                                      |

## Example

Suppose you have a table horiz\_table\_in.

```

horiz_table_in(iid1 VARCHAR2(30), iid2 VARCHAR2(30), iid3 VARCHAR2(30), iid4
VARCHAR2(30), iid5 VARCHAR2(30));

```

and the data in horiz\_table\_in looks as follows:

```

('apple', 'banana', NULL, NULL, NULL)
('apple', 'milk', 'banana', NULL, NULL)
('orange', NULL, NULL, NULL, NULL)

```

Suppose you want to find out what combinations of items is frequent with a given support threshold of 30%, requiring itemset containing at least one of ('apple','banana','orange'), but excluding any of ('milk') in any itemset. You use the following query:

```

CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as FI_VARCHAR_NT) itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL(
    CURSOR(SELECT iid1, iid2, iid3, iid4, iid5
        FROM horiz_table_in),
    0.3,
    2,
    5,
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT
        ('apple','banana','orange'))),
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT('milk'))));

```

## 77.1.2 FI\_TRANSACTIONAL Function

This procedure counts all frequent itemsets given a cursor for input data which is in 'TRANSACTIONAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total number of transactions.

In 'TRANSACTIONAL' row format, each transaction is spread across multiple rows. All the rows of a given transaction have the same transaction id, and each row has a different item id. Combining all of the item ids which share a given transaction id results in a single transaction.

### Syntax

```

DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL (
    tranx_cursor      IN      SYSREFCURSOR,
    support_threshold IN      NUMBER,
    itemset_length_min IN      NUMBER,
    itemset_length_max IN      NUMBER,
    including_items    IN      SYS_REFCURSOR DEFAULT NULL,
    excluding_items    IN      SYS_REFCURSOR DEFAULT NULL)
RETURN TABLE OF ROW (
    itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
    support      NUMBER,
    length       NUMBER,
    total_tranx  NUMBER);

```

### Parameters

**Table 77-4** *FI\_TRANSACTIONAL Function Parameters*

| Parameter    | Description                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tranx_cursor | The cursor parameter that the user will supply when calling the function. It should return two columns in its returning row, the first column being the transaction id, the second column being the item id. The item id must be number or character type (for example, VARCHAR2(n)). |

**Table 77-4 (Cont.) FI\_TRANSACTIONAL Function Parameters**

| Parameter          | Description                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| support_threshold  | A fraction number of total transaction count. An itemset is termed "frequent" if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a NUMBER. |
| itemset_length_min | The minimum length for interested frequent itemset. The parameter must be a NUMBER between 1 and 20, inclusive.                                                                                                               |
| itemset_length_max | The maximum length for interested frequent itemset. This parameter must be a NUMBER between 1 and 20, inclusive, and must not be less than itemset_length_min.                                                                |
| including_items    | A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that will be returned. The default is NULL.                                                              |
| excluding_items    | A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that will returned. The default is NULL.                                                                            |

### Return Values

**Table 77-5 FI\_TRANSACTIONAL Return Values**

| Parameter   | Description                                                                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| support     | The number of transactions in which a frequent itemset occurs. This will be returned as a NUMBER.                                                                    |
| itemset     | A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor. |
| length      | Number of items in a frequent itemset. This will be returned as a NUMBER.                                                                                            |
| total_tranx | The total transaction count. This will be returned as a NUMBER, and will be the same for all returned rows, similar to a reporting aggregate.                        |

### Usage Notes

Applications must predefine a nested table type of the input item type and cast the output itemset into this predefined nested table type before further processing, such as loading into a table.

### Examples

Suppose that the input table tranx\_table\_in looks as follows:

```
(1, 'apple')
(1, 'banana')
(2, 'apple')
(2, 'milk')
(2, 'banana')
(3, 'orange')
```

and the user is trying to find itemsets that satisfy a support-threshold of 60% and have the itemset-length greater than 1 (namely, (apple, banana)).

The output of this function would contain the following output row:

```
itemset=('apple','banana'), support=2, length=2, total_tranx=3
```

You need to create a nested table of item type before you submit a query to perform the frequent itemset counting. In this example, since item is of VARCHAR2(30), you must create a nested table of VARCHAR2(30):

```
CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as FI_VARCHAR_NT) itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
    cursor(SELECT tid, iid FROM tranx_table_in),
    0.6,
    2,
    5,
    NULL,
    NULL));
```

Here is another example to illustrate how to include certain items and exclude certain items in the counting.

```
SELECT CAST(itemset as FI_VARCHAR_NT) itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
    CURSOR(SELECT tid, iid FROM tranx_table_in),
    0.6,
    2,
    5,
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT
        ('apple','banana','orange'))),
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT('milk')))));
```

Using the including/excluding items parameter, you are able to further optimize the execution by ignoring itemsets that are not expected by application.

You can also use transactional output through collection unnesting:

```
SELECT
    bt.setid, nt.*
FROM
    (SELECT cast(Itemset as FI_VARCHAR_NT) itemset, rownum setid
    FROM table(
        DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
            CURSOR(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
            NULL, NULL))) bt,
    table(bt.itemset) nt;
```

If you want to use an insert statement to load frequent itemsets into a nested table, it is better to use the NESTED\_TABLE\_FAST\_INSERT hint for performance:

```
CREATE TABLE fq_nt (coll FI_VARCHAR_NT) NESTED TABLE coll STORE AS
    coll_nest;
INSERT /*+ NESTED_TABLE_FAST_INSERT */ INTO fq_nt
SELECT cast(itemset as FI_VARCHAR_NT)
FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
    cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
    NULL, NULL));
```

Note that if you want to use the package inside a PL/SQL cursor, you must cast the return type of the table function:

```

CREATE TYPE fi_res AS OBJECT (
    itemset      FI_VARCHAR_NT,
    support      NUMBER,
    length       NUMBER,
    total_tranx  NUMBER
);
/
CREATE TYPE fi_coll AS TABLE OF fi_res;
/

DECLARE
    cursor freqC is
        SELECT Itemset
        FROM table(
            CAST(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
                cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
                NULL, NULL) AS fi_coll));
    coll_nt  FI_VARCHAR_NT;
    num_rows int;
    num_itms int;
BEGIN
    num_rows := 0;
    num_itms := 0;
    OPEN freqC;
    LOOP
        FETCH freqC INTO coll_nt;
        EXIT WHEN freqC%NOTFOUND;
        num_rows := num_rows + 1;
        num_itms := num_itms + coll_nt.count;
    END LOOP;
    CLOSE freqC;
    DBMS_OUTPUT.PUT_LINE('Totally ' || num_rows || ' rows ' || num_itms || '
items were produced.');
```

```

END;
/
```

# DBMS\_FS

The `DBMS_FS` package for performing operations on an Oracle file system (make, mount, unmount and destroy operations) in an Oracle database.

This chapter contains the following topics:

- [DBMS\\_FS Overview](#)
- [DBMS\\_FS Security Model](#)
- [Summary of DBMS\\_FS Subprograms](#)

## 78.1 DBMS\_FS Overview

The `DBMS_FS` package contains Oracle file system (OFS) procedures that you can use to create, mount, unmount, and destroy an Oracle file system.

Starting 19c release, the file systems are supported by PDB. Oracle Database supports maximum 5 file systems per PDB and 1000 file systems in total.

The `DBMS_FS` package enables applications to access database objects from a universal client such as an NFS server. This feature interfaces with Oracle SecureFiles to provide the file system access.

### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for a detailed description of managing an NFS server in Oracle Database

## 78.2 DBMS\_FS Security Model

You must have the `SYSDBA` administrative privilege to use the `DBMS_FS` package.

The operations that you perform using the `DBMS_FS` package are equivalent to the file system operations that are performed in an operating system by the root user. Access to the individual file system that is created and mounted by this package is enforced using Access Control Lists (ACLs) and the permissions on the mounted directories to the operating system user.

## 78.3 Summary of DBMS\_FS Subprograms

This table lists the `DBMS_FS` subprograms and briefly describes them.

**Table 78-1 DBMS\_FS Subprograms**

| Subprogram                                  | Description                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">DESTROY_ORACLE_FS Procedure</a> | Destroys an Oracle file system, using the <code>fstype</code> and of name <code>fsname</code>  |
| <a href="#">MAKE_ORACLE_FS Procedure</a>    | Creates a file system of type specified by <code>fstype</code> and of name <code>fsname</code> |
| <a href="#">MOUNT_ORACLE_FS Procedure</a>   | Mounts an Oracle file system on the specified mount point                                      |
| <a href="#">UNMOUNT_ORACLE_FS Procedure</a> | Unmounts an Oracle file system on the specified mount point                                    |

### 78.3.1 DESTROY\_ORACLE\_FS Procedure

This procedure destroys an Oracle file system and then frees the resources that were associated with it. Run the `dbms_fs.destroy_oracle_fs()` procedure to destroy file systems that are no longer in use.

#### Syntax

```
DBMS_FS.DESTROY_ORACLE_FS (  
    fstype      IN VARCHAR2,  
    fsname      IN VARCHAR2);
```

#### Parameters

**Table 78-2 DBMS\_FS Parameters**

| Parameter           | Description                                                                               |
|---------------------|-------------------------------------------------------------------------------------------|
| <code>fstype</code> | File system type. Oracle File System (OFS) and Database File System (DBFS) are supported. |
| <code>fsname</code> | Name of the file system                                                                   |

#### Usage Notes

- You can find information about the currently mounted file systems by querying the `V$OFSMOUNT` dynamic view.
- For more information about the file system types, see the `fstype` description in [MAKE\\_ORACLE\\_FS Procedure](#).
- Before you run the `DBMS_FS.DESTROY_ORACLE_FS` procedure, you must unmount the file system by using the `DBMS_FS.UNMOUNT_ORACLE_FS` procedure. If you run this procedure on a file system that is still in use, it results in an error.
- After you run `DBMS_FS.DESTROY_ORACLE_FS`, Oracle Database destroys the file system and frees the associated resources.

#### Example

The following sample code shows how to destroy a DBFS file system, `dbfs_fs1`.

```
BEGIN  
    DBMS_FS.DESTROY_ORACLE_FS (
```

```
fstype          => 'dbfs',  
fsname          => 'dbfs_fs1');  
END;  
/
```

## 78.3.2 MAKE\_ORACLE\_FS Procedure

This procedure creates a new file system of type `DBFS` or `OFS`, on top of an existing Oracle tablespace or other database object.

### Syntax

```
DBMS_FS.MAKE_ORACLE_FS (  
    fstype      IN VARCHAR2,  
    fsname      IN VARCHAR2,  
    fsoptions   IN VARCHAR2);
```

### Parameters

**Table 78-3 DBMS\_FS Parameters**

| Parameter              | Description                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fstype</code>    | File system type. Enter one of the following values: <ul style="list-style-type: none"><li><code>ofs</code>—to create an Oracle File System</li><li><code>dbfs</code>—to create a Database File System</li></ul> |
| <code>fsname</code>    | Name of the file system. Enter a string no longer than 256 characters, using alphanumeric characters.                                                                                                            |
| <code>fsoptions</code> | Specify an existing tablespace to use for the Oracle file system, using the following format:<br><br>"tablespace=tablespace_name"                                                                                |

### Usage Notes

- If you want to create a database file system (DBFS), then you must run the `dbfs_create_filesystem.sql` script, which in turn calls the `dbfs_create_filesystem_advanced.sql` script. By default, this script is in the `$ORACLE_HOME/rdbms/admin` directory. When you run this script, provide the name of an existing tablespace and a name for the file system that will be stored in the database. The size of the file system will be the same as the table size. For example, to create a file system in the `dbfs_ts` tablespace, in the file system `dbfs_tab`:

```
@/$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem.sql dbfs_ts dbfs_tab
```

After you run this script, you can use the other procedures in the `DBMS_FS` package to mount, unmount, and destroy the file system.

#### Note:

Starting Oracle Database 19.3.1.0 release, the `DBMS_FS.MAKE_ORACLE_FS` is used to create a `DBFS` filesystem; hence no auxiliary SQL script is needed to create a `DBFS` filesystem.

- Running the `DBMS_FS.MAKE_ORACLE_FS` procedure on the database instance is equivalent to running the `mkfs` command by root in an operating system.
- The tablespace that you specified in the `fsoptions` parameter must already exist before you execute the `DBMS_FS.MAKE_ORACLE_FS` procedure. To find existing tablespaces, query the `DBA_TABLESPACES` data dictionary view.
- The size of the file system is the same size as this tablespace.

### Example

The following example shows how to create a DBFS file system named `dbfs_fs1` in the tablespace `dbfs_fs1_tbsp`.

```
BEGIN
  DBMS_FS.MAKE_ORACLE_FS (
    fstype      => 'dbfs',
    fsname      => 'dbfs_fs1',
    fsoptions   => 'TABLESPACE=dbfs_fs1_tbsp');
END;
/
```

## 78.3.3 MOUNT\_ORACLE\_FS Procedure

Use the `dbms_fs.mount_oracle_fs()` procedure to mount an Oracle file system or OFS managed file system on the specified mount point.

Before you begin, complete the following checks to ensure that:

- You have created the file system using the `dbms_fs.make_oracle_fs()` procedure.
- The mount point that you specify exists in the local node.
- The Oracle user has access permissions.
- The mount path is empty, which means that the directory specified by the mount point does not have any files.

Oracle supports an extensive list of mount options that you can use to have better control on resources and achieve good performance. The file system is mounted and is visible through a mounted path on the compute node. In case of RAC, mount the file system in each RAC cluster node independently.

Since OFSD is a non-fatal background process, it gets automatically restarted after the death of a process. File systems that are mounted at the time of the death of the OFSD process are automatically remounted after starting a new OFSD process. This ensures continuous availability of the mounted file systems even in the case of an error.

To improve the throughput, OFSD has its own local cache for writes and reads. The write cache uses 8 (1 MB) buffers per file connection, and it can use up to 256 MB per file system. You can modify this value through the mount option, `wcache_size`. A read-ahead algorithm is implemented for read operation and it uses 2 (1 MB) per file connection and it can use up to 256 MB per file system. Use the mount option, `rcache_size`, to modify this value.

The file system gets mounted and is visible through a mounted path on the compute node. In the case of RAC, the mount should be performed in each RAC cluster node independently.

The read-write cache is maintained per node, so this provides local cache consistency. In an Oracle RAC environment, consistency is guaranteed only after the `flush()` or `close()` operation is performed on the file. When two different processes on two different RAC nodes

modify a single file and write to the same offset, then the first process that performs the `close()` operation on the file will have its data written into the file.

### Syntax

```
DBMS_FS.MOUNT_ORACLE_FS (
    fstype           IN VARCHAR2,
    fsname           IN VARCHAR2,
    mount_point      IN VARCHAR2,
    mount_options    IN VARCHAR2);
```

### Parameters

**Table 78-4 MOUNT\_ORACLE\_FS Procedure Parameters**

| Parameter                  | Description                                                                                                                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fstype</code>        | File system type. Oracle File System (OFS) and Database File System (DBFS) are supported.                                                                                                                                                |
| <code>fsname</code>        | Name of the file system. Enter a string no longer than 256 characters, using alpha numeric characters.                                                                                                                                   |
| <code>mount_point</code>   | Local directory where the file system should be mounted. This directory must already exist. Enter an absolute path. The maximum number of mount points that you can create is 5 mount points per PDB and 1000 mount points per instance. |
| <code>mount_options</code> | Comma-separated mount options, listed in <a href="#">Table 78-5</a> .                                                                                                                                                                    |

### Usage Notes

**Table 78-5 Supported Mount Options for the MOUNT\_ORACLE\_FS procedure**

| Mount Option                     | Usage Description                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>default_permissions</code> | Enables permission check and restrict access based on file mode. This option is useful with the <code>allow_other</code> mount option.                                                                                                                                                                                            |
| <code>allow_other</code>         | Allows other users apart from the operating system user that did the mount can access the files. This will be used in conjunction with permission checks in determining the file access. This option requires setting the <code>user_allow_other</code> parameter in the <code>/etc/fuse.conf</code> configuration file on Linux. |
| <code>max_read</code>            | Maximum size of the read operation. No maximum size is set by default.                                                                                                                                                                                                                                                            |
| <code>max_write</code>           | Maximum write size in a single request. The default is 128K.                                                                                                                                                                                                                                                                      |
| <code>direct_io</code>           | Indicates to the operating system kernel not use file system cache.                                                                                                                                                                                                                                                               |
| <code>ro</code>                  | Mounts the file system in read-only mode. Files cannot be modified.                                                                                                                                                                                                                                                               |
| <code>rw</code>                  | Mounts the file system as read-write. This is the default.                                                                                                                                                                                                                                                                        |
| <code>nosuid</code>              | Specifies that the file system cannot contain set userid files.                                                                                                                                                                                                                                                                   |
| <code>suid</code>                | Specifies that the file system can contain set userid files. This is the default.                                                                                                                                                                                                                                                 |
| <code>exec</code>                | Allows executing a file under the mount path. This option is enabled by default.                                                                                                                                                                                                                                                  |
| <code>noexec</code>              | Prohibits executing a file under the mount path. Use this option to disallow any file to be executed in the file system.                                                                                                                                                                                                          |

**Table 78-5 (Cont.) Supported Mount Options for the MOUNT\_ORACLE\_FS procedure**

| Mount Option             | Usage Description                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| atime                    | Maintains information about the time when the file was accessed. This option is enabled by default.                                                                                                                                                                                                                                                                                          |
| noatime                  | Does not maintain information about the time when the file was accessed. When you enable this option, it increases throughput as the access time is not updated for every read operation.                                                                                                                                                                                                    |
| max_readahead=N          | Sets the maximum size for the read-ahead operations to the specified bytes. The default value depends on the versions of the kernel and FUSE in your operating system.                                                                                                                                                                                                                       |
| sync_read                | Permits only synchronous reads. If you use this option, it disables read-ahead caching for OFS.                                                                                                                                                                                                                                                                                              |
| async_read               | Permits asynchronous reads. All read and write operations in the file system are performed asynchronously. This is the default option for FUSE versions 7.6 or later.                                                                                                                                                                                                                        |
| dirsync                  | Makes all directory operations synchronous. FUSE utilizes this option.                                                                                                                                                                                                                                                                                                                       |
| big_writes               | Permits writes larger than 4KB. This is the default option for FUSE versions 7.6 or later.                                                                                                                                                                                                                                                                                                   |
| no_big_writes            | Does not allow writes larger than 4KB. This is not a recommended option for OFS.                                                                                                                                                                                                                                                                                                             |
| xattr_enabled            | Enables the use of extended attributes. Specify this option only if you want to use extended attributes.                                                                                                                                                                                                                                                                                     |
| kernel_cache_mode        | Makes the Linux kernel cache behave like a writeback cache when you enter <code>writeback</code> as the value for this option. A writeback cache provides better performance when there are many small input-output requirements. FUSE utilizes this option. Permitted values are: <code>writeback</code> and <code>write-through</code> . The default value is <code>write-through</code> . |
| kernel_cache_attr_time=N | Sets the Linux kernel attribute cache timeout to N seconds. The default value is infinity. Oracle recommends that you set low values for RAC setup.                                                                                                                                                                                                                                          |
| wcache_size=N            | Sets the OFS write cache size to N bytes. The default value is 256 MB.                                                                                                                                                                                                                                                                                                                       |
| rcache_size=N            | Sets the OFS read cache size to N bytes. The default value is 256 MB.                                                                                                                                                                                                                                                                                                                        |
| posix_locks              | Implements the POSIX file locks in OFS. This is not supported by OFS. If you want to use the file-locking mechanism, use the <code>noposix_locks</code> option.                                                                                                                                                                                                                              |
| noposix_locks            | Implements POSIX file locks in Linux kernel. This is the default option.                                                                                                                                                                                                                                                                                                                     |

**Note:**

The following options are exclusive options and cannot be used together:

- `ro/rw`
- `nosuid/suid`
- `exec/noexec`
- `atime/noatime`
- `big_writes/no_big_writes`
- `sync_read/async_read`
- `posix_locks/noposix_locks`

**Usage Notes**

- This procedure makes the file system visible in the local database instance.
- For more information about the file system types, see the `fstype` description in [MAKE\\_ORACLE\\_FS Procedure](#).
- You can find information about currently mounted file systems by querying the `V$OFSMOUNT` dynamic view.
- Run the `DBMS_FS.MOUNT_ORACLE_FS` procedure on a file system that has already been created with `DBMS_FS.MAKE_ORACLE_FS` in the local computer node where the Oracle database instance is running. You cannot run this procedure on file systems that were created outside of Oracle Database.
- You cannot update the mount options after mounting the file system. If you want to change the mount options later, you'll have to unmount the file system, and then remount it.

**Example: Mounts a DBFS file system**

Mounts a DBFS file system at `/oracle/dbfs/testfs`.

```
BEGIN
  DBMS_FS.MOUNT_ORACLE_FS (
    fstype          => 'dbfs',
    fsname          => 'dbfs_fs1',
    mount_point     => '/oracle/dbfs/testfs',
    mount_options   => 'default_permissions, allow_other');
END;
```

## 78.3.4 UNMOUNT\_ORACLE\_FS Procedure

This procedure unmounts an Oracle file system on the specified mount point.

File systems that are mounted in a PDB are automatically unmounted when the PDB is closed. You can also use `dbms_fs.unmount_oracle_fs()` to explicitly unmount an Oracle file system that you have mounted through OFS.

**Syntax**

```
DBMS_FS.UNMOUNT_ORACLE_FS (
  fsname          IN VARCHAR2,
```

```

mount_point      IN VARCHAR2,
unmount_options  IN VARCHAR2);

```

**Table 78-6 UNMOUNT\_ORACLE\_FS Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fsname          | Name of the file system.                                                                                                                                                                                                                                                                                                             |
| mount_point     | Local directory where the file system had been mounted. Enter an absolute path.                                                                                                                                                                                                                                                      |
| unmount_options | Optionally, enter <code>force</code> to unmount the file system forcibly. This setting prevents new requests from being sent to the file system. All pending requests on the file system are either completed or cancelled. If you omit this setting, then attempts to unmount a busy file system cause an <code>EBUSY</code> error. |

**Usage Notes**

- Before you unmount the file system, ensure that all applications that use this file system are shut down. Also ensure that no processes reference the mounting file system.
- You can find information about the currently mounted file systems by querying the `V$OFSMOUNT` dynamic view.
- For more information about the file system types, see the `fstype` description in [MAKE\\_ORACLE\\_FS Procedure](#).
- When an Oracle instance is shut down in normal immediate mode, then all the mounted file systems are automatically unmounted.
- If you perform a `SHUTDOWN ABORT`, then the file system may still show as mounted but it may not be accessible. In this case, you can unmount the system manually by calling the `unmount` command at the operating system level or the `fusermount` procedure on Linux systems.
- Do not use `fusermount -u` to unmount a running file system as it causes inconsistency in Oracle views, such as `v$ofsmount`.
- You can export the local mount point of an Oracle file system to point to the remote system, and then NFS mount the file system from the remote system by using the operating system `mount` command. The `DBMS_FS.MOUNT_ORACLE_FS` procedure is similar to `mount` commands that are used for other local file systems.
- For better security, Oracle recommends that you use access control lists (ACLs) and Kerberos to control access to sensitive data.
- Do not attempt to unmount the file system from the operating system level. Doing so can leave the Oracle Database-created file system internal tables in an inconsistent state.

**Example**

The following sample code unmounts a DBFS mounted file system at `/oracle/dbfs/testfs`.

```

BEGIN
  DBMS_FS.UNMOUNT_ORACLE_FS (
    fsname      => 'dbfs_fs1',
    mount_point => '/oracle/dbfs/testfs',
    mount_options => 'force');
END;

```

# DBMS\_GOLDENGATE\_ADM

The `DBMS_GOLDENGATE_ADM` package provides subprograms to configure and manage Oracle GoldenGate conflict detection and resolution.

This chapter contains the following topics:

- [Using DBMS\\_GOLDENGATE\\_ADM](#)
- [Summary of DBMS\\_GOLDENGATE\\_ADM Subprograms](#)

## 79.1 Using DBMS\_GOLDENGATE\_ADM

This section contains topics which relate to using the `DBMS_GOLDENGATE_ADM` package.

- [DBMS\\_GOLDENGATE\\_ADM Overview](#)
- [DBMS\\_GOLDENGATE\\_ADM Security Model](#)

### 79.1.1 DBMS\_GOLDENGATE\_ADM Overview

The `DBMS_GOLDENGATE_ADM` package provides interfaces to configure automatic conflict detection and resolution in an Oracle GoldenGate configuration that replicates tables between Oracle databases.

When more than one replica of a table allows changes to the table, a conflict can occur when a change is made to the same row in two different databases at nearly the same time. Oracle GoldenGate replicates changes using row logical change records (LCRs). It detects a conflict by comparing the old values in the row LCR with the current values of the corresponding table row identified by the key columns. If any column value does not match, then there is a conflict. After a conflict is detected, Oracle GoldenGate can resolve the conflict by overwriting values in the row with some values from the row LCR, ignoring the values in the row LCR, or computing a delta to update the row values.

XStream inbound servers and outbound servers can be used in an XStream configuration in a multitenant container database (CDB). A CDB is an Oracle database that includes zero, one, or many user-created pluggable databases (PDBs).

**Note:**

Using XStream requires purchasing a license for the Oracle GoldenGate product.

**See Also:**

## 79.1.2 DBMS\_GOLDENGATE\_ADM Security Model

Security on this package can be controlled either by granting `EXECUTE` on this package to selected users or roles or by granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

An Oracle GoldenGate administrator must be configured at each Oracle database in the table's replication environment, and Oracle GoldenGate must be configured to replicate the table at each Oracle database. You can configure an Oracle GoldenGate administrator using the `GRANT_ADMIN_PRIVILEGE` procedure in the `DBMS_GOLDENGATE_ADM` package.

## 79.2.1 ADD\_AUTO\_CDR Procedure

This procedure configures Oracle GoldenGate automatic conflict detection and resolution for a table.

The conflict detection and resolution configured by this procedure is based on the timestamp of the changes. The procedure adds one or more hidden columns of `TIMESTAMP` type to the table, and each hidden column is counted against the limit of 1,000 columns for each table.

The procedure automatically places the columns in the table into a default column group and into an unconditional supplemental log group, excluding nonscalar columns. To create column groups that include a subset of the columns in the table, use the `ADD_AUTO_CDR_COLUMN_GROUP` procedure in this package.

### Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR(
    schema_name          IN VARCHAR2,
    table_name           IN VARCHAR2,
    resolution_granularity IN VARCHAR2 DEFAULT 'ROW',
    existing_data_timestamp IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
    tombstone_deletes     IN BOOLEAN DEFAULT TRUE,
    fetchcols             IN BOOLEAN DEFAULT TRUE,
    record_conflicts      IN BOOLEAN DEFAULT FALSE,
    use_custom_handlers   IN BINARY_INTEGER DEFAULT 0);
```

### Parameters

**Table 79-2 ADD\_AUTO\_CDR Procedure Parameters**

| Parameter                           | Description                                                                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schema_name</code>            | The name of the table's schema.                                                                                                                                                                                                     |
| <code>table_name</code>             | The name of the table.                                                                                                                                                                                                              |
| <code>resolution_granularity</code> | ROW, the default, adds one hidden <code>TIMESTAMP</code> column for the row and one hidden <code>TIMESTAMP</code> column for each LOB column.<br>COLUMN adds one hidden <code>TIMESTAMP</code> column for each column in the table. |

**Table 79-2 (Cont.) ADD\_AUTO\_CDR Procedure Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| existing_data_timestamp | Timestamp to assign to existing rows.<br>If NULL, then the current system timestamp is used. If a time is specified, and the operating system time zone is not a valid Oracle time zone, then Oracle uses UTC as the default value.                                     |
| tombstone_deletes       | TRUE, the default, tracks deleted rows in a tombstone table. Tracking deleted rows might be required to detect and resolve some conflicts, but tracking deleted rows requires additional database resources.<br>FALSE does not track deleted rows in a tombstone table. |
| fetchcols               | TRUE, the default, fetches the value of LOBs during conflict detection and resolution. Fetching LOBs can be an expensive operation.<br>FALSE does not fetch the value of LOBs during conflict detection and resolution.                                                 |
| record_conflicts        | TRUE records the conflict in the DBA_APPLY_ERROR and DBA_APPLY_ERROR_MESSAGES views.<br>FALSE, the default, does not record the conflict.                                                                                                                               |
| use_custom_handlers     | 0, the default, indicates that automatic conflict handlers are used.<br>1 indicates that automatic conflict handlers are not used and that a custom error handler must be specified using the SET_DML_HANDLER procedure in the DBMS_APPLY_ADM package.                  |

## 79.2.2 ADD\_AUTO\_CDR\_COLUMN\_GROUP Procedure

This procedure adds a column group to a table that is configured for Oracle GoldenGate automatic conflict detection and resolution.

For a table that has been configured for timestamp conflict detection and resolution, this procedure adds a column group that includes a specified subset of columns in the table. Any columns in the table that are not part of a column group remain in the default column group for the table.

When you add a column group to a table, conflict detection and resolution is performed on the columns in the column group separately from the other columns in the table. Column groups enable different databases to update different columns in the same row at nearly the same time without causing a conflict.

For example, a replicated table that contains employee information might have a salary column and a bonus column as well as other columns that identify the employee and a location column for the employee's office number. Assume that one department in the company updates its database to change the employee's salary while another department updates its database to change the employee's location. If the salary and bonus columns are in a column group, these changes are applied to the replicated table in each database without requiring conflict resolution.

The procedure automatically places the columns in the column group into an unconditional supplemental log group, excluding nonscalar columns.

Before this procedure can be run on a table, the `DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR` procedure must be run in the table with `ROW` specified for the `resolution_granularity` parameter.

### Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR_COLUMN_GROUP (
    schema_name      IN VARCHAR2,
    table_name       IN VARCHAR2,
    column_list      IN VARCHAR2,
    column_group_name IN VARCHAR2 DEFAULT NULL,
    existing_data_timestamp IN TIMESTAMP WITH TIME ZONE DEFAULT NULL);
```

### Parameters

**Table 79-3 ADD\_AUTO\_CDR\_COLUMN\_GROUP Procedure Parameters**

| Parameter                            | Description                                                                                                                                                                                                                                                                             |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schema_name</code>             | The name of the table's schema.                                                                                                                                                                                                                                                         |
| <code>table_name</code>              | The name of the table.                                                                                                                                                                                                                                                                  |
| <code>column_list</code>             | Group of columns for which the conflict detection and resolution is configured.<br>Specify the columns in a comma-separated list.<br>The same column cannot be in more than one column group.<br>Also, the same column cannot be in a column group and specified in a delta resolution. |
| <code>column_group_name</code>       | The name of the column group.<br>If <code>NULL</code> , the column group name is system generated.                                                                                                                                                                                      |
| <code>existing_data_timestamp</code> | The time value for the added <code>TIMESTAMP</code> columns for existing table data.                                                                                                                                                                                                    |

## 79.2.3 ADD\_AUTO\_CDR\_DELTA\_RES Procedure

This procedure configures Oracle GoldenGate automatic conflict detection and delta resolution for the column.

The resolution method does not depend on a timestamp or an extra resolution column. With delta conflict resolution, the conflict is resolved by adding the difference between the new and old values in the LCR to the value in the table. For example, if a bank balance is updated at two sites concurrently, then the converged value accounts for all debits and credits. This resolution method is generally used for financial data such as an account balance.

The procedure automatically places the column into an unconditional supplemental log group.

Before this procedure can be run on a table, the `DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR` procedure must be run in the table with `ROW` specified for the `resolution_granularity` parameter.

### Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR_DELTA_RES (
    schema_name IN VARCHAR2,
    table_name  IN VARCHAR2,
    column_name IN VARCHAR2);
```

## Parameters

**Table 79-4 ADD\_AUTO\_CDR\_DELTA\_RES Procedure Parameters**

| Parameter   | Description                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name | The name of the table's schema.                                                                                                             |
| table_name  | The name of the table.                                                                                                                      |
| column_name | The name of the column.<br>The specified column must be a NUMBER or FLOAT data type column.<br>The same column cannot be in a column group. |

## 79.2.4 ALTER\_AUTO\_CDR Procedure

This procedure alters the Oracle GoldenGate automatic conflict detection and resolution for a table.

### Syntax

```
DBMS_GOLDENGATE_ADM.ALTER_AUTO_CDR(
    schema_name      IN VARCHAR2,
    table_name       IN VARCHAR2,
    tombstone_deletes IN BOOLEAN DEFAULT NULL,
    fetchcols        IN BOOLEAN DEFAULT NULL,
    record_conflicts  IN BOOLEAN DEFAULT NULL,
    use_custom_handlers IN BINARY_INTEGER DEFAULT NULL);
```

## Parameters

**Table 79-5 ALTER\_AUTO\_CDR Procedure Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name       | The name of the table's schema.                                                                                                                                                                                                                                                                                  |
| table_name        | The name of the table.                                                                                                                                                                                                                                                                                           |
| tombstone_deletes | TRUE tracks deleted rows in a tombstone table. Tracking deleted rows might be required to detect and resolve some conflicts, but tracking deleted rows requires additional database resources.<br>FALSE does not track deleted rows in a tombstone table.<br>NULL retains the current setting for the parameter. |
| fetchcols         | TRUE fetches the value of nonscalar columns during conflict detection and resolution.<br>FALSE does not fetch the value of nonscalar columns during conflict detection and resolution.<br>NULL retains the current setting for the parameter.                                                                    |
| record_conflicts  | TRUE records the conflict.<br>FALSE does not record the conflict.<br>NULL retains the current setting for the parameter.                                                                                                                                                                                         |

**Table 79-5 (Cont.) ALTER\_AUTO\_CDR Procedure Parameters**

| Parameter           | Description                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| use_custom_handlers | 0 indicates that automatic conflict handlers are used.<br>1 indicates that automatic conflict handlers are not used and that a custom error handler must be specified using the SET_DML_HANDLER procedure in the DBMS_APPLY_ADM package.<br>NULL, the default, retains the current setting for the parameter. |

## 79.2.5 ALTER\_AUTO\_CDR\_COLUMN\_GROUP Procedure

This procedure alters a column group for Oracle GoldenGate automatic conflict detection and resolution.

### Syntax

```
DBMS_GOLDENGATE_ADM.ALTER_AUTO_CDR_COLUMN_GROUP(
    schema_name      IN VARCHAR2,
    table_name       IN VARCHAR2,
    column_group_name IN VARCHAR2,
    add_column_list   IN VARCHAR2,
    remove_column_list IN VARCHAR2);
```

### Parameters

**Table 79-6 ALTER\_AUTO\_CDR\_COLUMN\_GROUP Procedure Parameters**

| Parameter          | Description                                                        |
|--------------------|--------------------------------------------------------------------|
| schema_name        | The name of the table's schema.                                    |
| table_name         | The name of the table.                                             |
| column_group_name  | The name of the column group.                                      |
| add_column_list    | A comma-separated list of columns to add to the column group.      |
| remove_column_list | A comma-separated list of columns to remove from the column group. |

## 79.2.6 DELETE\_PROCREP\_EXCLUSION\_OBJ Procedure

This procedure deletes a database object from the exclusion list for Oracle GoldenGate procedural replication.

When a database object is on the exclusion list for Oracle GoldenGate procedural replication, execution of subprogram in the package is not replicated if the subprogram operates on the excluded object. For example, if `hr.employees` is an excluded database object for the `DBMS_REDEFINITION` package, then an execution of the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure on the `hr.employees` table is not replicated.

 **Caution:**

Run the `DELETE_PROCREP_EXCLUSION_OBJ` procedure only under the direction of Oracle Support.

### Syntax

```
DBMS_GOLDENGATE_ADM.DELETE_PROCREP_EXCLUSION_OBJ(
  package_owner      IN VARCHAR2 DEFAULT NULL,
  package_name       IN VARCHAR2 DEFAULT NULL,
  object_owner       IN VARCHAR2 DEFAULT NULL,
  object_name        IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 79-7** `DELETE_PROCREP_EXCLUSION_OBJ` Procedure Parameters

| Parameter                  | Description               |
|----------------------------|---------------------------|
| <code>package_owner</code> | The owner of the package. |
| <code>package_name</code>  | The name of the package.  |
| <code>object_owner</code>  | The owner of the object.  |
| <code>object_name</code>   | The name of the object.   |

## 79.2.7 GG\_PROEDURE\_REPLICATION\_ON Function

This function returns 1 if Oracle GoldenGate procedural replication is enabled and returns 0 if it is disabled.

### Syntax

```
DBMS_GOLDENGATE_ADM.GG_PROEDURE_REPLICATION_ON
RETURN NUMBER;
```

## 79.2.8 INSERT\_PROCREP\_EXCLUSION\_OBJ Procedure

This procedure inserts a database object into the exclusion list for Oracle GoldenGate procedural replication.

When a database object is on the exclusion list for Oracle GoldenGate procedural replication, execution of subprogram in the package is not replicated if the subprogram operates on the excluded object. For example, if `hr.employees` is an excluded database object for the `DBMS_REDEFINITION` package, then an execution of the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure on the `hr.employees` table is not replicated.

 **Caution:**

Run the `INSERT_PROCREP_EXCLUSION_OBJ` procedure only under the direction of Oracle Support.

## Syntax

```
DBMS_GOLDENGATE_ADM.INSERT_PROCREP_EXCLUSION_OBJ(
    package_owner    IN VARCHAR2 DEFAULT NULL,
    package_name     IN VARCHAR2 DEFAULT NULL,
    object_owner     IN VARCHAR2 DEFAULT NULL,
    object_name      IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 79-8 INSERT\_PROCREP\_EXCLUSION\_OBJ Procedure Parameters**

| Parameter     | Description               |
|---------------|---------------------------|
| package_owner | The owner of the package. |
| package_name  | The name of the package.  |
| object_owner  | The owner of the object.  |
| object_name   | The name of the object.   |

## 79.2.9 PURGE\_TOMBSTONES Procedure

This procedure purges rows that were deleted before the specified timestamp from the tombstone table.

## Syntax

```
DBMS_GOLDENGATE_ADM.PURGE_TOMBSTONES(
    purge_timestamp IN TIMESTAMP WITH TIME ZONE);
```

## Parameters

**Table 79-9 PURGE\_TOMBSTONES Procedure Parameters**

| Parameter       | Description                                    |
|-----------------|------------------------------------------------|
| purge_timestamp | The timestamp before which records are purged. |

## 79.2.10 REMOVE\_AUTO\_CDR Procedure

This procedure removes Oracle GoldenGate automatic conflict detection and resolution for a table.

## Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR(
    schema_name     IN VARCHAR2,
    table_name      IN VARCHAR2);
```

## Parameters

**Table 79-10 REMOVE\_AUTO\_CDR Procedure Parameters**

| Parameter   | Description                     |
|-------------|---------------------------------|
| schema_name | The name of the table's schema. |
| table_name  | The name of the table.          |

## 79.2.11 REMOVE\_AUTO\_CDR\_COLUMN\_GROUP Procedure

This procedure removes a column group that was configured for Oracle GoldenGate automatic conflict detection and resolution.

### Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR_COLUMN_GROUP (
    schema_name      IN VARCHAR2,
    table_name       IN VARCHAR2,
    column_group_name IN VARCHAR2);
```

## Parameters

**Table 79-11 REMOVE\_AUTO\_CDR\_COLUMN\_GROUP Procedure Parameters**

| Parameter         | Description                     |
|-------------------|---------------------------------|
| schema_name       | The name of the table's schema. |
| table_name        | The name of the table.          |
| column_group_name | The name of the column group.   |

## 79.2.12 REMOVE\_AUTO\_CDR\_DELTA\_RES Procedure

This procedure removes Oracle GoldenGate automatic conflict detection and delta resolution for the column.

### Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR_DELTA_RES (
    schema_name IN VARCHAR2,
    table_name  IN VARCHAR2,
    column_name IN VARCHAR2);
```

## Parameters

**Table 79-12 REMOVE\_AUTO\_CDR\_DELTA\_RES Procedure Parameters**

| Parameter   | Description                     |
|-------------|---------------------------------|
| schema_name | The name of the table's schema. |
| table_name  | The name of the table.          |
| column_name | The name of the column.         |

# DBMS\_GOLDENGATE\_AUTH

The `DBMS_GOLDENGATE_AUTH` package provides subprograms for granting privileges to and revoking privileges from GoldenGate administrators.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Summary of DBMS\\_GOLDENGATE\\_AUTH Subprograms](#)

## See Also:

[GRANT\\_ADMIN\\_PRIVILEGE Procedure](#) in the `DBMS_XSTREAM_AUTH` package

## 80.1 DBMS\_GOLDENGATE\_AUTH Overview

This package provides subprograms for granting privileges to GoldenGate administrators and revoking privileges from GoldenGate administrators. A GoldenGate administrator manages an integrated GoldenGate and XStream Out configuration.

GoldenGate administrators can be used in a multitenant container database (CDB). A CDB is an Oracle database that includes zero, one, or many user-created pluggable databases (PDBs).

## See Also:

- [GRANT\\_ADMIN\\_PRIVILEGE Procedure](#) in the `DBMS_XSTREAM_AUTH` package
- *Oracle Database XStream Guide*
- *Oracle Database Concepts* for more information about CDBs and PDBs

## 80.2 DBMS\_GOLDENGATE\_AUTH Security Model

Security on this package can be controlled by granting `EXECUTE` on this package to selected users or roles, or by granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

The user executing the subprograms in the `DBMS_GOLDENGATE_AUTH` package must have `SYSDBA` administrative privilege, and the user must exercise the privilege using `AS SYSDBA` at connect time.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

To ensure that the user who runs the subprograms in this package has the necessary privileges, connect as an administrative user who can create users, grant privileges, and create tablespaces when using this package.

## 80.3 Summary of DBMS\_GOLDENGATE\_AUTH Subprograms

The `DBMS_XSTREAM_AUTH` package includes the `GRANT_ADMIN_PRIVILEGE` procedure and `REVOKE_ADMIN_PRIVILEGE` procedure subprograms.

**Table 80-1 DBMS\_GOLDENGATE\_AUTH Package Subprograms**

| Subprogram                                       | Description                                                                                                                                 |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GRANT_ADMIN_PRIVILEGE Procedure</a>  | Either grants the privileges needed by a user to be a GoldenGate administrator directly, or generates a script that grants these privileges |
| <a href="#">REVOKE_ADMIN_PRIVILEGE Procedure</a> | Either revokes GoldenGate administrator privileges from a user directly, or generates a script that revokes these privileges                |

### Note:

All subprograms commit unless specified otherwise.

### 80.3.1 GRANT\_ADMIN\_PRIVILEGE Procedure

This procedure grants the privileges needed by a user to be a GoldenGate administrator.

### See Also:

[GRANT\\_ADMIN\\_PRIVILEGE Procedure](#) in the `DBMS_XSTREAM_AUTH` package

### Syntax

```
DBMS_GOLDENGATE_AUTH.GRANT_ADMIN_PRIVILEGE(
  grantee           IN  VARCHAR2,
  privilege_type    IN  VARCHAR2  DEFAULT '*',
  grant_select_privileges IN  BOOLEAN  DEFAULT TRUE,
  do_grants         IN  BOOLEAN  DEFAULT TRUE,
  file_name         IN  VARCHAR2  DEFAULT NULL,
  directory_name    IN  VARCHAR2  DEFAULT NULL,
  grant_optional_privileges IN  VARCHAR2  DEFAULT NULL,
  container         IN  VARCHAR2  DEFAULT 'CURRENT');
```

## Parameters

**Table 80-2 GRANT\_ADMIN\_PRIVILEGE Procedure Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grantee                 | The user to whom privileges are granted                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| privilege_type          | Specify one of the following values: <ul style="list-style-type: none"> <li>CAPTURE<br/>Specifying CAPTURE grants the minimum privileges required by the user to administer Oracle GoldenGate integrated extract.</li> <li>APPLY<br/>Specifying APPLY grants the minimum privileges required by the user to administer Oracle GoldenGate integrated replicat.</li> <li>*</li> </ul> Specifying * grants the minimum privileges required by the user to administer Oracle GoldenGate integrated extract and Oracle GoldenGate integrated replicat.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| grant_select_privileges | If TRUE, then the procedure grants a set of privileges, including SELECT_CATALOG_ROLE, to the user. This setting is recommended for GoldenGate administrators.<br><br>If FALSE, then the procedure does not grant the set of privileges to the user.<br><br>SELECT_CATALOG_ROLE enables the user to select from the data dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| do_grants               | If TRUE, then the procedure grants the privileges to the specified grantee directly, and adds the grantee to the DBA_GOLDENGATE_PRIVILEGES data dictionary view. If the user already has an entry in this data dictionary view, then the procedure does not make another entry, and no error is raised. If TRUE and any of the grant statements fails, then the procedure raises an error.<br><br>If FALSE, then the procedure does not grant the privileges to the specified grantee directly, and does not add the grantee to the DBA_GOLDENGATE_PRIVILEGES data dictionary view. You specify FALSE when the procedure is generating a file that you will run later. If you specify FALSE and either the file_name or directory_name parameter is NULL, then the procedure raises an error.<br><br>Note: It is recommended that do_grants be set to TRUE because many APIs check for the presence of a user in the DBA_GOLDENGATE_PRIVILEGES view, which will not be populated if do_grants is set to FALSE. |
| file_name               | The name of the file generated by the procedure. The file contains all of the statements that grant the privileges. If a file with the specified file name exists in the specified directory name, then the grant statements are appended to the existing file.<br><br>If NULL, then the procedure does not generate a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 80-2 (Cont.) GRANT\_ADMIN\_PRIVILEGE Procedure Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| directory_name            | <p>The directory into which the generated file is placed. The specified directory must be a directory object created using the SQL statement <code>CREATE DIRECTORY</code>. If you specify a directory, then the user who invokes the procedure must have the <code>WRITE</code> privilege on the directory object.</p> <p>If the <code>file_name</code> parameter is <code>NULL</code>, then this parameter is ignored, and the procedure does not generate a file.</p> <p>If <code>NULL</code> and the <code>file_name</code> parameter is non-<code>NULL</code>, then the procedure raises an error.</p>                                                                                                                                               |
| grant_optional_privileges | <p>A comma-separated list of optional privileges to grant to the grantee. You can specify the following roles and privileges:</p> <ul style="list-style-type: none"> <li>• <code>XDBADMIN</code></li> <li>• <code>DV_XSTREAM_ADMIN</code></li> <li>• <code>DV_GOLDENGATE_ADMIN</code></li> <li>• <code>EXEMPT_ACCESS_POLICY</code></li> <li>• <code>EXEMPT_REDACTION_POLICY</code></li> </ul>                                                                                                                                                                                                                                                                                                                                                             |
| container                 | <p>If <code>CURRENT</code>, then grants privileges to the grantee only in the container where the procedure is invoked. <code>CURRENT</code> can be specified while connected to the root or to a PDB.</p> <p>If <code>ALL</code>, then grants privileges to the grantee in all containers in the CDB and all PDBs created after the procedure is invoked. To specify <code>ALL</code>, the procedure must be invoked in the root by a common user.</p> <p>If a container name, then grants privileges to the grantee only in the specified container. To specify root, use <code>CDB\$ROOT</code> while connected to the root. To specify a PDB, the procedure must be invoked in the root.</p> <p><b>Note:</b> This parameter only applies to CDBs.</p> |

### Usage Notes

The user who runs the procedure must be an administrative user who can grant privileges to other users.

Specifically, the procedure grants the following privileges to the specified user:

- The `RESTRICTED SESSION` system privilege
- `EXECUTE` on the following packages:
  - `DBMS_APPLY_ADM`
  - `DBMS_AQ`
  - `DBMS_AQADM`
  - `DBMS_AQIN`
  - `DBMS_AQELM`
  - `DBMS_CAPTURE_ADM`
  - `DBMS_FLASHBACK`
  - `DBMS_LOCK`
  - `DBMS_PROPAGATION_ADM`

- DBMS\_RULE\_ADM
- DBMS\_TRANSFORM
- DBMS\_XSTREAM\_ADM
- Privileges to enqueue messages into and dequeue messages from any queue
- Privileges to manage any queue
- Privileges to create, alter, and execute any of the following types of objects in the user's own schema and in other schemas:
  - Evaluation contexts
  - Rule sets
  - Rules

In addition, the grantee can grant these privileges to other users.

- SELECT\_CATALOG\_ROLE
- SELECT or READ privilege on data dictionary views related to GoldenGate and Oracle Replication
- The ability to allow a remote GoldenGate administrator to perform administrative actions through a database link by connecting to the grantee

This ability is enabled by running the GRANT\_REMOTE\_ADMIN\_ACCESS procedure in this package.

#### Note:

This procedure grants only the privileges necessary to configure and administer a GoldenGate environment. You can grant additional privileges to the grantee if necessary.

## 80.3.2 REVOKE\_ADMIN\_PRIVILEGE Procedure

This procedure revokes GoldenGate administrator privileges from a user.

### Syntax

```
DBMS_GOLDENGATE_AUTH.REVOKE_ADMIN_PRIVILEGE(
  grantee                IN  VARCHAR2,
  privilege_type          IN  VARCHAR2  DEFAULT '*',
  revoke_select_privileges IN  BOOLEAN   DEFAULT FALSE,
  do_revokes              IN  BOOLEAN   DEFAULT TRUE,
  file_name               IN  VARCHAR2  DEFAULT NULL,
  directory_name          IN  VARCHAR2  DEFAULT NULL,
  revoke_optional_privileges IN VARCHAR2  DEFAULT NULL,
  container               IN  VARCHAR2  DEFAULT 'CURRENT');
```

## Parameters

**Table 80-3 REVOKE\_ADMIN\_PRIVILEGE Procedure Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grantee                    | The user from whom privileges are revoked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| privilege_type             | Specify one of the following values: <ul style="list-style-type: none"> <li>CAPTURE<br/>Specifying CAPTURE revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated extract.</li> <li>APPLY<br/>Specifying APPLY revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated replicat.</li> <li>*</li> </ul> Specifying * revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated extract and Oracle GoldenGate integrated replicat.                                                                                                                                                                                                                                                                                                                                                            |
| revoke_select_privileges   | If TRUE, then the procedure revokes SELECT_CATALOG_ROLE from the user.<br>If FALSE, then the procedure does not revoke SELECT_CATALOG_ROLE to the user.<br>SELECT_CATALOG_ROLE enables the user to select from the data dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| do_revokes                 | If TRUE, then the procedure revokes the privileges from the specified user directly, and removes the user from the DBA_XSTREAM_ADMINISTRATOR data dictionary view. If the user does not have a record in this data dictionary view, then the procedure does not remove a record from the view, and no error is raised. If TRUE and any of the revoke statements fails, then the procedure raises an error. A revoke statement fails if the user is not granted the privilege that is being revoked.<br>If FALSE, then the procedure does not revoke the privileges from the specified user directly, and does not remove the user from the DBA_XSTREAM_ADMINISTRATOR data dictionary view.<br>You specify FALSE when the procedure is generating a file that you will run later. If you specify FALSE and either the file_name or directory_name parameter is NULL, then the procedure does not raise an error. |
| file_name                  | The name of the file generated by this procedure. The file contains all of the statements that revoke the privileges. If a file with the specified file name exists in the specified directory name, then the revoke statements are appended to the existing file.<br>If NULL, then the procedure does not generate a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| directory_name             | The directory into which the generated file is placed. The specified directory must be a directory object created using the SQL statement CREATE DIRECTORY. If you specify a directory, then the user who invokes the procedure must have the WRITE privilege on the directory object.<br>If the file_name parameter is NULL, then this parameter is ignored, and the procedure does not generate a file.<br>If NULL and the file_name parameter is non-NULL, then the procedure raises an error.                                                                                                                                                                                                                                                                                                                                                                                                               |
| revoke_optional_privileges | A comma-separated list of optional privileges to revoke from the grantee, such as the DV_XSTREAM_ADMIN and DV_GOLDENGATE_ADMIN privileges                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 80-3 (Cont.) *REVOKE\_ADMIN\_PRIVILEGE Procedure Parameters*

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| container | <p>If <code>CURRENT</code>, then revokes privileges from the grantee only in the container where the procedure is invoked. <code>CURRENT</code> can be specified while connected to the root or to a PDB.</p> <p>If <code>ALL</code>, then revokes privileges from the grantee in all containers in the CDB. To specify <code>ALL</code>, the procedure must be invoked in the root.</p> <p>If a container name, then revokes privileges from the grantee only in the specified container. To specify root, use <code>CDB\$ROOT</code> while connected to the root. To specify a PDB, the procedure must be invoked in the root.</p> <p><b>Note:</b> This parameter only applies to CDBs.</p> |

Usage Notes

The user who runs this procedure must be an administrative user who can revoke privileges from other users. Specifically, this procedure revokes the privileges granted by running the `GRANT_ADMIN_PRIVILEGE` procedure in this package.

## DBMS\_HADOOP

The `DBMS_HADOOP` package provides a PL/SQL procedure called `CREATE_EXTDDL_FOR_HIVE()`, that creates an Oracle external table for a given hive table.

Big Data SQL needs to be correctly set up for `DBMS_HADOOP` to work.

This chapter contains the following topics:

- [DBMS\\_HADOOP Overview](#)
- [DBMS\\_HADOOP Security Model](#)
- [Summary of DBMS\\_HADOOP Subprograms](#)

### 81.1 DBMS\_HADOOP Overview

The `DBMS_HADOOP` package provides two procedures for creating an Oracle external table and for synchronizing the Oracle external table partitions.

These procedures are:

- `CREATE_EXTDDL_FOR_HIVE()` — creates an Oracle external table for a given hive table
- `SYNCHRONIZE_PARTITIONS_FOR_HIVE()` — helps to synchronize the Oracle external table partitions with those in the corresponding hive table

### 81.2 DBMS\_HADOOP Security Model

Users must have `ALTER` privileges on the table for modifying external table parameters. In addition the `ALTER` privileges, users must have `READ` privileges for the directory object that contains the external data source and `WRITE` privileges for the directory objects containing bad, log, and discard files.

Similar privileges are applicable to the partitioned external tables.

### 81.3 Summary of DBMS\_HADOOP Subprograms

`DBMS_HADOOP` includes the `CREATE_EXTDDL_FOR_HIVE` procedure and `SYNC_PARTITIONS_FOR_HIVE` procedure subprograms.

**Table 81-1 DBMS\_HADOOP Subprograms**

| Subprogram                                            | Description                                                                                                                     |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_EXTDDL_FOR_HIVE Procedure</a>      | Given a hive table name, creates a text of DDL that can be executed to create an external table corresponding to the hive table |
| <a href="#">CREATE_HYBRID_PARTNED_TABLE Procedure</a> | Merges a given partitioned Hive table with an Oracle partitioned table, and replaces it with the merged table.                  |

**Table 81-1 (Cont.) DBMS\_HADOOP Subprograms**

| Subprogram                                                | Description                                                                         |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">SYNCHRONIZE_PARTITIONS_FOR_HIVE Procedure</a> | Synchronizes the existing partitioning definition of a hive table in Oracle catalog |

### 81.3.1 CREATE\_EXTDDL\_FOR\_HIVE Procedure

This procedure creates an Oracle external table for a given hive table.

#### Syntax

```
DBMS_HADOOP.CREATE_EXTDDL_FOR_HIVE (
  cluster_id      IN  VARCHAR2,
  db_name         IN  VARCHAR2 := NULL,
  hive_table_name IN  VARCHAR2,
  hive_partition  IN  BOOLEAN,
  table_name      IN  VARCHAR2 := NULL,
  perform_DDL     IN  BOOLEAN := FALSE,
  text_of_DDL     OUT CLOB);
```

#### Parameters

**Table 81-2 CREATE\_EXTDDL\_FOR\_HIVE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster_id      | Hadoop cluster ID                                                                                                                                                                                                                                                                                                                                                                                           |
| hive_db_name    | Database where the hive table is located                                                                                                                                                                                                                                                                                                                                                                    |
| hive_table_name | Name of the hive table                                                                                                                                                                                                                                                                                                                                                                                      |
| hive_partition  | If this argument is TRUE and if the original hive table is partitioned, the corresponding Oracle external table will also be partitioned using the same partition key(s).<br><br>If the original hive table is not partitioned, hive_partition=TRUE has no effect. If hive_partition=FALSE, the corresponding Oracle external table will not be partitioned even if the original hive table is partitioned. |
| table_name      | Name of the Oracle external table                                                                                                                                                                                                                                                                                                                                                                           |
| perform_DDL     | If this argument is TRUE, the external table will be automatically created. Otherwise, only the textual representation of the DDL statement will be generated and returned in text_of_DDL .                                                                                                                                                                                                                 |
| text_of_DDL     | If the argument perform_DDL is FALSE, only the textual representation of the DDL statement will be generated and returned in text_of_DDL .                                                                                                                                                                                                                                                                  |

## 81.3.2 CREATE\_HYBRID\_PARTNED\_TABLE Procedure

This procedure merges the partitioned Hive table with an Oracle partitioned table, and replace it with the merged table.

### Syntax

```
DBMS_HADOOP.CREATE_HYBRID_PARTNED_TABLE (
  cluster_id          IN      VARCHAR2,
  db_name             IN      VARCHAR2,
  hive_table_name     IN      VARCHAR2,
  table_name          IN      VARCHAR2,
  table_owner         IN      VARCHAR2,
  perform_ddl         IN      BOOLEAN := TRUE,
  text_of_ddl         OUT     CLOB);
```

### Parameters

**Table 81-3 CREATE\_HYBRID\_PARTNED\_TABLE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster_id      | Hadoop cluster ID                                                                                                                                                                                                               |
| db_name         | Database where the partitioned Hive table is located                                                                                                                                                                            |
| hive_table_name | Name of the partitioned Hive table                                                                                                                                                                                              |
| table_name      | Name of the partitioned Oracle table                                                                                                                                                                                            |
| table_owner     | The owner of the partitioned Oracle table                                                                                                                                                                                       |
| perform_DDL     | If the value of this parameter is TRUE, the external table is automatically created.<br>If the value of this parameter is FALSE, only the textual representation of the DDL statement is generated and returned in text_of_DDL. |
| text_of_DDL     | If the argument perform_DDL is FALSE, only the textual representation of the DDL statement is generated and returned in text_of_DDL.                                                                                            |

## 81.3.3 SYNCHRONIZE\_PARTITIONS\_FOR\_HIVE Procedure

This procedure synchronizes the Oracle external table partitions with those in the corresponding hive table.

### Syntax

```
DBMS_HADOOP.SYNCHRONIZE_PARTITIONS_FOR_HIVE (
  table_name      IN  VARCHAR2,
  table_owner     IN  VARCHAR2);
```

## Parameters

**Table 81-4   SYNCHRONIZE\_PARTITIONS\_FOR\_HIVE Procedure Parameters**

| Parameter   | Description           |
|-------------|-----------------------|
| table_name  | Oracle external table |
| table_owner | Schema name           |

# DBMS\_HANG\_MANAGER

The DBMS\_HANG\_MANAGER package provides a method of changing some Hang Manager configuration parameters.

This chapter contains the following topics:

- [DBMS\\_HANG\\_MANAGER Overview](#)
- [DBMS\\_HANG\\_MANAGER Security Model](#)
- [DBMS\\_HANG\\_MANAGER Constants](#)
- [DBMS\\_HANG\\_MANAGER Exceptions](#)
- [Summary of DBMS\\_HANG\\_MANAGER Subprograms](#)

## 82.1 DBMS\_HANG\_MANAGER Overview

The DBMS\_HANG\_MANAGER package provides a method of changing some Hang Manager configuration parameters.

Hang Manager is always enabled on all databases, Automatic Storage Management (ASM) disk groups, and single instance systems (when not using Oracle RAC). Hang resolution is enabled on all instances by default except for single instance systems (when not using Oracle RAC) where it is disabled and cannot be enabled at this time.

### Note:

The DBMS\_HANG\_MANAGER package is intended for use by database administrators (DBA) only. It is not intended for use by application developers.

## 82.2 DBMS\_HANG\_MANAGER Security Model

DBMS\_HANG\_MANAGER can only be run as the SYS user.

## 82.3 DBMS\_HANG\_MANAGER Constants

The table in this topic lists DBMS\_HANG\_MANAGER package constants.

**Table 82-1 DBMS\_HANG\_MANAGER Constants**

| Name             | Type     | Value            | Description                     |
|------------------|----------|------------------|---------------------------------|
| RESOLUTION_SCOPE | VARCHAR2 | resolution scope | Resolution scope parameter name |
| SENSITIVITY      | VARCHAR2 | sensitivity      | Sensitivity parameter name      |

**Table 82-1 (Cont.) DBMS\_HANG\_MANAGER Constants**

| Name                      | Type     | Value                                | Description                                                                                                                  |
|---------------------------|----------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| BASE_FILE_SIZE_LIMIT      | VARCHAR2 | base file size limit                 | Base file size limit parameter name. The default value of this parameter is 100 MB.                                          |
| BASE_FILE_SET_COUNT       | VARCHAR2 | base file set count                  | Base file set count parameter name. The default value is 5 trace files in the circular trace file set.                       |
| LWS_FILE_SIZE_LIMIT       | VARCHAR2 | long waiting session file size limit | Long waiting session file size limit parameter name. The default value of this parameter is 100 MB.                          |
| LWS_FILE_SET_COUNT        | VARCHAR2 | long waiting session set count       | Long waiting session set count parameter name. The default value is 5 trace files in the circular trace file set.            |
| RESOLUTION_SCOPE_PROCESS  | VARCHAR2 | PROCESS                              | Enables only session and/or process termination                                                                              |
| RESOLUTION_SCOPE_INSTANCE | VARCHAR2 | INSTANCE                             | Enables session, process, and instance termination. The latter is used in specific scenarios. The default value is INSTANCE. |
| SENSITIVITY_NORMAL        | VARCHAR2 | NORMAL                               | Sets various Hang Manager intervals to their default values. The default value is NORMAL.                                    |
| SENSITIVITY_HIGH          | VARCHAR2 | HIGH                                 | Sets the various Hang Manager intervals to half of their default values                                                      |

## 82.4 DBMS\_HANG\_MANAGER Exceptions

The table in this topic lists the exceptions raised by the DBMS\_HANG\_MANAGER package.

**Table 82-2 DBMS\_HANG\_MANAGER Package Exceptions**

| Exception                | Error Code | Description                                       |
|--------------------------|------------|---------------------------------------------------|
| ERRNUM_INPUT_ERROR       | -32706     | Invalid user input                                |
| ERRNUM_INTERNAL_ERROR    | -32707     | Database experienced an error setting a parameter |
| ERRNUM_UNSUPPORTED_ERROR | -32708     | Operation is not supported on this instance type  |

## 82.5 Summary of DBMS\_HANG\_MANAGER Subprograms

The DBMS\_HANG\_MANAGER package includes the SET procedure subprogram.

**Table 82-3 DBMS\_HANG\_MANAGER Package Subprograms**

| Subprogram                    | Description                                         |
|-------------------------------|-----------------------------------------------------|
| <a href="#">SET Procedure</a> | Sets the specified parameter to the specified value |

### 82.5.1 SET Procedure

This procedure sets the specified parameters to specified values.

#### Syntax

```
DBMS_HANG_MANAGER.SET (  
    pname    IN  VARCHAR2,  
    pvalue   IN  VARCHAR2);
```

#### Parameters

**Table 82-4 SET Procedure Parameters**

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| pname     | Contains the parameter name that needs to be modified            |
| pvalue    | Contains the new value for the parameter name specified in pname |

# DBMS\_HEAT\_MAP

The `DBMS_HEAT_MAP` package provides an interface to externalize heatmaps at various levels of storage including block, extent, segment, object and tablespace. A second set of subprograms externalize the heatmaps materialized by the background for top N tablespaces.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Summary of DBMS\\_HEAT\\_MAP Subprograms](#)

 **See Also:**

- Heat Map in *Oracle Database VLDB and Partitioning Guide*
- [DBMS\\_ILM](#)
- [DBMS\\_ILM\\_ADMIN](#)

## 83.1 DBMS\_HEAT\_MAP Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database.

The Heat Map tracks modification times at the block level, and multiple access statistics at the segment level. Objects in the `SYSTEM` and `SYSAUX` tablespaces are not tracked. `DBMS_HEAT_MAP` gives you access to the Heat Map statistics at various levels - block, extent, segment, object, and tablespace.

## 83.2 DBMS\_HEAT\_MAP Security Model

The execution privilege is granted to `PUBLIC`. Procedures in this package run under the caller security. The user must have `ANALYZE` privilege on the object.

## 83.3 Summary of DBMS\_HEAT\_MAP Subprograms

This table lists and briefly describes the `DBMS_HEAT_MAP` package subprograms.

**Table 83-1 DBMS\_HEAT\_MAP Package Subprograms**

| Subprogram                              | Description                                                      |
|-----------------------------------------|------------------------------------------------------------------|
| <a href="#">BLOCK_HEAT_MAP Function</a> | Returns last modification time for each block in a table segment |

**Table 83-1 (Cont.) DBMS\_HEAT\_MAP Package Subprograms**

| Subprogram                                   | Description                                                                                        |
|----------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">EXTENT_HEAT_MAP Function</a>     | Returns the extent level Heat Map statistics for a table segment                                   |
| <a href="#">OBJECT_HEAT_MAP Function</a>     | Returns the minimum, maximum and average access times for all the segments belonging to the object |
| <a href="#">SEGMENT_HEAT_MAP Procedure</a>   | Returns the heatmap attributes for the given segment                                               |
| <a href="#">TABLESPACE_HEAT_MAP Function</a> | Returns the minimum, maximum and average access times for all the segments in the tablespace       |

### 83.3.1 BLOCK\_HEAT\_MAP Function

This table function returns the last modification time for each block in a table segment. It returns no information for segment types that are not data.

#### Syntax

```
DBMS_HEAT_MAP.BLOCK_HEAT_MAP (
    owner          IN VARCHAR2,
    segment_name   IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL,
    sort_columnid  IN NUMBER DEFAULT NULL,
    sort_order     IN VARCHAR2 DEFAULT NULL)
RETURN hm_bls_row PIPELINED;
```

#### Parameters

**Table 83-2 BLOCK\_HEAT\_MAP Function Parameters**

| Parameter      | Description                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| owner          | Owner of the segment                                                                                                                                |
| segment_name   | Table name of a non-partitioned table or (sub)partition of partitioned table. Returns no rows when table name is specified for a partitioned table. |
| partition_name | Defaults to NULL. For a partitioned table, specify the partition or subpartition segment name.                                                      |
| sort_columnid  | ID of the column on which to sort the output. Valid values 1..9. Invalid values are ignored.                                                        |
| sort_order     | Defaults to NULL. Possible values: ASC, DESC                                                                                                        |

#### Return Values

**Table 83-3 BLOCK\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter      | Description                               |
|----------------|-------------------------------------------|
| owner          | Owner of the segment                      |
| segment_name   | Segment name of the non-partitioned table |
| partition_name | Partition or subpartition name            |

**Table 83-3 (Cont.) BLOCK\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter       | Description                                      |
|-----------------|--------------------------------------------------|
| tablespace_name | Tablespace containing the segment                |
| file_id         | Absolute file number of the block in the segment |
| relative_fno    | Relative file number of the block in the segment |
| block_id        | Block number of the block                        |
| write time      | Last modification time of the block              |

## 83.3.2 EXTENT\_HEAT\_MAP Function

This table function returns the extent level Heat Map statistics for a table segment. It returns no information for segment types that are not data. Aggregates at extent level, including minimum modification time and maximum modification time, are included.

### Syntax

```
DBMS_HEAT_MAP.EXTENT_HEAT_MAP (
    owner          IN VARCHAR2,
    segment_name   IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL,
    RETURN hm_els_row PIPELINED;
```

### Parameters

**Table 83-4 EXTENT\_HEAT\_MAP Function Parameters**

| Parameter      | Description                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| owner          | Owner of the segment                                                                                                                                |
| segment_name   | Table name of a non-partitioned table or (sub)partition of partitioned table. Returns no rows when table name is specified for a partitioned table. |
| partition_name | Defaults to NULL. For a partitioned table, specify the partition or subpartition segment name.                                                      |

### Return Values

**Table 83-5 EXTENT\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter       | Description                                      |
|-----------------|--------------------------------------------------|
| owner           | Owner of the segment                             |
| segment_name    | Segment name of the non-partitioned table        |
| partition_name  | Partition or subpartition name                   |
| tablespace_name | Tablespace containing the segment                |
| file_id         | Absolute file number of the block in the segment |
| relative_fno    | Relative file number of the block in the segment |
| block_id        | Block number of the block                        |

**Table 83-5 (Cont.) EXTENT\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter     | Description                                    |
|---------------|------------------------------------------------|
| blocks        | Number of blocks in the extent                 |
| bytes         | Number of bytes in the extent                  |
| min_writetime | Minimum of last modification time of the block |
| max_writetime | Maximum of last modification time of the block |
| avg_writetime | Average of last modification time of the block |

### 83.3.3 OBJECT\_HEAT\_MAP Function

This table function returns the minimum, maximum and average access times for all the segments belonging to the object.

The object must be a table. The table function raises an error if called on object tables other than table.

#### Syntax

```
DBMS_HEAT_MAP.OBJECT_HEAT_MAP (
    object_owner      IN VARCHAR2,
    object_name       IN VARCHAR2)
RETURN hm_object_table PIPELINED;
```

#### Parameters

**Table 83-6 OBJECT\_HEAT\_MAP Function Parameters**

| Parameter    | Description                         |
|--------------|-------------------------------------|
| object_owner | Tablespace containing the segment   |
| object_name  | Segment header relative file number |

#### Return Values

**Table 83-7 OBJECT\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter       | Description                                     |
|-----------------|-------------------------------------------------|
| segment_name    | Name of the top level segment                   |
| partition_name  | Name of the partition                           |
| tablespace_name | Name of the tablespace                          |
| segment_type    | Type of segment as in DBA_SEGMENTS.SEGMENT_TYPE |
| segment_size    | Segment size in bytes                           |
| min_writetime   | Oldest write time for the segment               |
| max_writetime   | Latest write time for the segment               |
| avg_writetime   | Average write time for the segment              |
| min_readtime    | Oldest read time for the segment                |

**Table 83-7 (Cont.) OBJECT\_HEAT\_MAP Function Return Values (Output Parameters)**

| Parameter      | Description                                  |
|----------------|----------------------------------------------|
| max_readtime   | Latest read time for the segment             |
| avg_writetime  | Average write time for the segment           |
| min_lookuptime | Oldest index lookup time for the segment     |
| max_lookuptime | Latest index lookup time for the segment     |
| avg_lookuptime | Average index lookup time for the segment    |
| min_ftstime    | Oldest full table scan time for the segment  |
| max_ftstime    | Latest full table scan time for the segment  |
| avg_ftstime    | Average full table scan time for the segment |

### 83.3.4 SEGMENT\_HEAT\_MAP Procedure

This procedure returns the heatmap attributes for the given segment.

#### Syntax

```
DBMS_HEAT_MAP.SEGMENT_HEAT_MAP (
    tablespace_id      IN  NUMBER,
    header_file        IN  NUMBER,
    header_block       IN  NUMBER,
    segment_objd       IN  NUMBER,
    min_writetime      OUT DATE,
    max_writetime      OUT DATE,
    avg_writetime      OUT DATE,
    min_readtime       OUT DATE,
    max_readtime       OUT DATE,
    avg_readtime       OUT DATE,
    min_lookuptime     OUT DATE,
    max_lookuptime     OUT DATE,
    avg_lookuptime     OUT DATE,
    min_ftstime        OUT DATE,
    max_ftstime        OUT DATE,
    avg_ftstime        OUT DATE);
```

#### Parameters

**Table 83-8 SEGMENT\_HEAT\_MAP Procedure Parameters**

| Parameter     | Description                         |
|---------------|-------------------------------------|
| tablespace_id | Tablespace containing the segment   |
| header_file   | Segment header relative file number |
| header_block  | Segment header block number         |
| segment_objd  | DATAOBJ of the segment              |

## Return Values

**Table 83-9** *SEGMENT\_HEAT\_MAP Procedure Return Values (Output Parameters)*

| Parameter      | Description                                  |
|----------------|----------------------------------------------|
| min_writetime  | Oldest write time for the segment            |
| max_writetime  | Latest write time for the segment            |
| avg_writetime  | Average write time for the segment           |
| min_readtime   | Oldest read time for the segment             |
| max_readtime   | Latest read time for the segment             |
| avg_writetime  | Average write time for the segment           |
| min_lookuptime | Oldest index lookup time for the segment     |
| max_lookuptime | Latest index lookup time for the segment     |
| avg_lookuptime | Average index lookup time for the segment    |
| min_ftstime    | Oldest full table scan time for the segment  |
| max_ftstime    | Latest full table scan time for the segment  |
| avg_ftstime    | Average full table scan time for the segment |

## 83.3.5 TABLESPACE\_HEAT\_MAP Function

This table function returns the minimum, maximum and average access times for all the segments in the tablespace.

### Syntax

```
DBMS_HEAT_MAP.TABLESPACE_HEAT_MAP (
    tablespace_name    IN VARCHAR2)
RETURN hm_tablespace_table PIPELINED;
```

### Parameters

**Table 83-10** *TABLESPACE\_HEAT\_MAP Procedure Parameters*

| Parameter       | Description            |
|-----------------|------------------------|
| tablespace_name | Name of the tablespace |

## Return Values

**Table 83-11** *TABLESPACE\_HEAT\_MAP Procedure Return Values (Output Parameters)*

| Parameter       | Description                                  |
|-----------------|----------------------------------------------|
| segment_count   | Total number of segments in the tablespace   |
| allocated_bytes | Space used by the segments in the tablespace |
| min_writetime   | Oldest write time for the segment            |
| max_writetime   | Latest write time for the segment            |

**Table 83-11 (Cont.) TABLESPACE\_HEAT\_MAP Procedure Return Values (Output Parameters)**

| Parameter      | Description                                  |
|----------------|----------------------------------------------|
| avg_writetime  | Average write time for the segment           |
| min_readtime   | Oldest read time for the segment             |
| max_readtime   | Latest read time for the segment             |
| avg_writetime  | Average write time for the segment           |
| min_lookuptime | Oldest index lookup time for the segment     |
| max_lookuptime | Latest index lookup time for the segment     |
| avg_lookuptime | Average index lookup time for the segment    |
| min_ftstime    | Oldest full table scan time for the segment  |
| max_ftstime    | Latest full table scan time for the segment  |
| avg_ftstime    | Average full table scan time for the segment |

# DBMS\_HIERARCHY

DBMS\_HIERARCHY contains subprograms for validating the data in tables used by hierarchies and analytic views.

This chapter contains the following topics:

- [DBMS\\_HIERARCHY Overview](#)
- [DBMS\\_HIERARCHY Security Model](#)
- [Summary of DBMS\\_HIERARCHY Subprograms](#)

## 84.1 DBMS\_HIERARCHY Overview

The DBMS\_HIERARCHY package contains functions for validating that the contents of a database table are suitable for use by an analytic view or a hierarchy, a function for verifying the success of the validation, and a procedure for creating a table for logging validation operations.

**Note:**

Names specified by parameters of the DBMS\_HIERARCHY subprograms are case-sensitive.

For information about using analytic views, see *Oracle Database Data Warehousing Guide*.

## 84.2 DBMS\_HIERARCHY Security Model

Summarizes security considerations for the validation of analytic view and hierarchy objects.

All procedures in this package validate that the current user has the necessary privileges on the specified objects and return an error if those privileges are not found.

**Note:**

To ensure that the user has enough tablespace to log validation operations, do one of the following:

- GRANT UNLIMITED TABLESPACE TO *username*;
- ALTER USERNAME *username* QUOTA *size* ON *tablespace\_name*;

The following system privileges are required to use this package:

**To validate objects in the user's own schema:**

- `CREATE TABLE` privilege for `CREATE_VALIDATE_LOG_TABLE` or to have `VALIDATE_ANALYTIC_VIEW` or `VALIDATE_HIERARCHY` automatically create a table
- `SELECT` privilege on the tables or views used by the analytic view or hierarchy
- `INSERT` privilege on the tables used by the attribute dimensions of the hierarchy or the fact table used by the analytic view

**To validate objects in different schemas:**

- `CREATE ANY TABLE` privilege for `CREATE_VALIDATE_LOG_TABLE` or to have the `VALIDATE_ANALYTIC_VIEW` or `VALIDATE_HIERARCHY` automatically create a table
- `INSERT ANY TABLE` privilege on the tables used by the attribute dimensions of the hierarchy or the fact table used by the analytic view

## 84.3 Summary of DBMS\_HIERARCHY Subprograms

This table lists the `DBMS_HIERARCHY` subprograms and briefly describes them.

| Subprogram                                           | Description                                                                                                                                               |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_VALIDATE_LOG_TABLE Procedure</a>  | Creates a table that you can use for logging messages generated by the <code>VALIDATE_HIERARCHY</code> and <code>VALIDATE_ANALYTIC_VIEW</code> functions. |
| <a href="#">UPGRADE_VALIDATE_LOG_TABLE Procedure</a> | This procedure takes a log table and upgrades it to the newest format. Returns an error if the table cannot be upgraded due to other errors.              |
| <a href="#">VALIDATE_ANALYTIC_VIEW Function</a>      | Validates that the data in a table is suitable for use by an analytic view.                                                                               |
| <a href="#">VALIDATE_CHECK_SUCCESS Function</a>      | Indicates whether a prior call to <code>VALIDATE_HIERARCHY</code> or <code>VALIDATE_ANALYTIC_VIEW</code> was successful or produced validation errors.    |
| <a href="#">VALIDATE_HIERARCHY Function</a>          | Validates that the data in a table is suitable for use by a hierarchy.                                                                                    |

### 84.3.1 CREATE\_VALIDATE\_LOG\_TABLE Procedure

This procedure creates a table that you can use for logging messages generated by the `VALIDATE_ANALYTIC_VIEW` or `VALIDATE_HIERARCHY` function, which validate data used by an analytic view or hierarchy.

The table that this procedure creates has the following structure.

| NAME         | NULL?    | DATATYPE           |
|--------------|----------|--------------------|
| -----        | -----    | -----              |
| LOG_NUMBER   | NOT NULL | NUMBER             |
| ACTION_ORDER | NOT NULL | NUMBER             |
| OBJECT_OWNER | NOT NULL | VARCHAR2(128 BYTE) |
| OBJECT_NAME  | NOT NULL | VARCHAR2(128 BYTE) |
| ACTION       | NOT NULL | VARCHAR2(10 BYTE)  |

```
TIME                NOT NULL TIMESTAMP(6)
ERROR_NUMBER        NUMBER
ERROR_MESSAGE        VARCHAR2(4000)
```

### Syntax

```
DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
    table_name        IN  VARCHAR2,
    owner_name        IN  VARCHAR2        DEFAULT NULL
    IGNORE_IF_EXISTS  IN  PL/SQL BOOLEAN  DEFAULT FALSE);
```

### Parameters

| Parameter        | Description                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| table_name       | The name of the table to create.                                                                                                                                                           |
| owner_name       | The name of the schema in which to create the table. If owner_name is NULL, then the table is created in the current user's schema.                                                        |
| IGNORE_IF_EXISTS | A Boolean that indicates whether to create the table if a table by the same name exists. If you specify a table, it must have the same structure as the table that this procedure creates. |

### Examples

#### Example 84-1 Creating a Validation Log Table

```
BEGIN
    DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
        'VAL_AV_HIERARCHY_LOG',
        'AV_USER',
        FALSE
    );
END;
/
```

## 84.3.2 UPGRADE\_VALIDATE\_LOG\_TABLE Procedure

This procedure takes a log table and upgrades it to the newest format. Returns an error if the table cannot be upgraded due to other errors.

### Syntax

```
DBMS_HIERARCHY.UPGRADE_VALIDATE_LOG_TABLE (
    table_name        IN  VARCHAR2,
    owner_name        IN  VARCHAR2        DEFAULT NULL);
```

### Parameters

| Parameter  | Description                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------|
| table_name | The name of the table to upgrade.                                                                                                 |
| owner_name | The name of the schema in which to find the table. If owner_name is NULL, then the table is created in the current user's schema. |

### 84.3.3 VALIDATE\_ANALYTIC\_VIEW Function

This function validates that the data in a table or view conforms to the logical constraints inherent in the definition of an analytic view.

#### Syntax

```
DBMS_HIERARCHY.VALIDATE_ANALYTIC_VIEW (  
    analytic_view_name          IN VARCHAR2    DEFAULT NULL,  
    analytic_view_owner_name    IN VARCHAR2    DEFAULT NULL,  
    log_table_name              IN VARCHAR2    DEFAULT NULL,  
    log_table_owner_name        IN VARCHAR2    DEFAULT NULL)  
RETURN NUMBER;
```

#### Parameters

| Parameter                | Description                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------|
| analytic_view_name       | The name of the analytic view to validate.                                                                    |
| analytic_view_owner_name | The name of the owner of the schema that contains the analytic view.                                          |
| log_table_name           | The name of the validation log table in which to put the results of the validation operation.                 |
| log_table_owner_name     | The name of the owner of the schema in which the validation log table exists or in which to create the table. |

#### Returns

The number of the entry in the validation log table for the validation results.

#### Usage Notes

If the `log_table_name` parameter is `NULL`, then the `VALIDATE_ANALYTIC_VIEW` function creates a validation log table. The name of the table it creates is `DBMS_HIERARCHY_LOG`.

When the validation operation begins, a row is inserted into the log table with the action of `START`. When the operation completes, a row is inserted into the log table with the action of `END`. When an error is detected, a row is inserted into the log table with the action of `ERROR`, and the associated `error_number` and `error_message` columns are populated. All rows inserted into the validation log table include a log number and the time of the insert.

The `VALIDATE_ANALYTIC_VIEW` function verifies that the following conditions are true for each attribute dimension the analytic view is dimensioned by:

- The key values found in the fact table for the attribute dimension must exist in the star schema dimension table for that attribute dimension.
- The referenced attribute values for the attribute dimension must be unique across all rows of the star schema dimension table for that dimension.

Also, for every hierarchy in the analytic view, the function verifies that the following conditions are true:

- The primary key of a level determines a unique value for each attribute of the level.

- For each row of the table or view used by the attribute dimension of the hierarchy, the value for every level key column (including alternate keys) of a NOT NULL level is non-NULL.
- For each row of the table or view, either all level key columns and alternate key columns of a SKIP WHEN NULL level must be NULL or they must all be non-NULL. This verifies that the alternate level key is determined by the level key.
- For each group of rows that have the same alternate key column values for a level, the key column values must have the same column values. This verifies that the level key is determined by the alternate level key, which is required for an alternate key.

### Examples

#### Example 84-2 Validating an Analytic View

```
DECLARE
    log_num NUMBER;
    obj_name VARCHAR2(8) := 'SALES_AV';
BEGIN
    log_num := DBMS_HIERARCHY.VALIDATE_ANALYTIC_VIEW(obj_name);
END;
/
```

## 84.3.4 VALIDATE\_CHECK\_SUCCESS Function

This function indicates whether a prior call to `VALIDATE_HIERARCHY` or `VALIDATE_ANALYTIC_VIEW` was successful or produced validation errors.

### Syntax

```
DBMS_HIERARCHY.VALIDATE_CHECK_SUCCESS (
    TOPOBJ_NAME          IN  VARCHAR2,
    TOPOBJ_OWNER         IN  VARCHAR2,
    LOG_NUMBER           IN  VARCHAR2
    LOG_TABLE_NAME       IN  VARCHAR2
    LOG_TABLE_OWNER_NAME IN  VARCHAR2 )
RETURN VARCHAR2;
```

### Parameters

| Parameter            | Description                                       |
|----------------------|---------------------------------------------------|
| TOPOBJ_NAME          | The name of the hierarchy or analytic view.       |
| TOPOBJ_OWNER         | The owner of the hierarchy or analytic view.      |
| LOG_NUMBER           | The number of the log entry.                      |
| LOG_TABLE_NAME       | The name of the log table.                        |
| LOG_TABLE_OWNER_NAME | The name of the schema in which the table exists. |

### Returns

A VARCHAR2 that is SUCCESS if no errors occurred or ERROR if errors did occur.

## Examples

### Example 84-3 Using VALIDATE\_CHECK\_SUCCESS

This example finds out whether the prior call to `VALIDATE_ANALYTIC_VIEW` encountered errors.

```
DECLARE
  log_num NUMBER;
  succ VARCHAR2(7);
  obj_name VARCHAR2(8) := 'SALES_AV';
BEGIN
  log_num := dbms_hierarchy.validate_analytic_view(obj_name);
  succ := dbms_hierarchy.validate_check_success(
    topobj_name => obj_name, log_number => log_num);
  IF (succ != 'SUCCESS') THEN
    RAISE_APPLICATION_ERROR(
      num => -20000,
      msg => 'Validate failed!');
  END IF;
END;
/
```

## 84.3.5 VALIDATE\_HIERARCHY Function

This function validates that the data in a table or view conforms to the logical constraints inherent in the definitions of an attribute dimension that uses the table or view and a hierarchy that uses the attribute dimension.

### Syntax

```
DBMS_HIERARCHY.VALIDATE_HIERARCHY (
  hier_name           IN VARCHAR2,
  hier_owner_name     IN VARCHAR2   DEFAULT NULL,
  log_table_name      IN VARCHAR2   DEFAULT NULL,
  log_table_owner_name IN VARCHAR2   DEFAULT NULL)
RETURN NUMBER;
```

### Parameters

| Parameter                         | Description                                                                                                   |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>hier_name</code>            | The name of the hierarchy to validate.                                                                        |
| <code>hier_owner_name</code>      | The name of the owner of the schema that contains the hierarchy.                                              |
| <code>log_table_name</code>       | The name of the validation log table in which to put the results of the validation operation.                 |
| <code>log_table_owner_name</code> | The name of the owner of the schema in which the validation log table exists or in which to create the table. |

### Returns

The number of the entry in the validation log table for the validation results.

## Usage Notes

If the `log_table_name` parameter is `NULL`, then the `VALIDATE_HIERARCHY` function creates a validation log table. The name of the table it creates is `DBMS_HIERARCHY_LOG`.

When the validation operation begins, a row is inserted into the log table with the action of `START`. When the operation completes, a row is inserted into the log table with the action of `END`. When an error is detected, a row is inserted into the log table with the action of `ERROR`, and the associated `error_number` and `error_message` columns are populated. All rows inserted into the validation log table include a log number and the time of the insert.

The `VALIDATE_HIERARCHY` function verifies that the following conditions are true for the hierarchy:

- The primary key of a level determines a unique value for each attribute of the level.
- For each row of the table or view used by the attribute dimension of the hierarchy, the value for every level key column (including alternate keys) of a `NOT NULL` level is non-`NULL`.
- For each row of the table or view, either all level key columns and alternate key columns of a `SKIP WHEN NULL` level must be `NULL` or they must all be non-`NULL`. This verifies that the alternate level key is determined by the level key.
- For each group of rows that have the same alternate key column values for a level, the key column values must have the same column values. This verifies that the level key is determined by the alternate level key, which is required for an alternate key.

## Examples

### Example 84-4 Validating a Hierarchy and Specifying a Table Name

This example validates the `PRODUCT_HIER` hierarchy and specifies that the results be inserted in the table named `VAL_AV_HIERARCHY_LOG`. The owner of the hierarchy and of the schema that contains the table is `AV_USER`.

```
-- Create a log table.
BEGIN
    DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
        'VAL_AV_HIERARCHY_LOG',
        'AV_USER',
        FALSE
    );
END;
/

-- Validate the hierarchy.
DECLARE
    log_num NUMBER;
    obj_name VARCHAR2(12) := 'PRODUCT_HIER';
    table_name VARCHAR2(28) := 'VAL_AV_HIERARCHY_LOG';
BEGIN
    log_num := DBMS_HIERARCHY.VALIDATE_HIERARCHY(obj_name, 'AV_USER',
    table_name);
END;
/
```

Query the log table.

```
SELECT LOG_NUMBER, ACTION, OBJECT_NAME, ERROR_NUMBER, ERROR_MESSAGE
FROM AV_USER.VAL_AV_HIERARCHY_LOG;
WHERE OBJECT_NAME = 'PRODUCT_HIER';
```

| LOG_NUMBER | ACTION | OBJECT_NAME  | ERROR_NUMBER | ERROR_MESSAGE |
|------------|--------|--------------|--------------|---------------|
| 1          | START  | PRODUCT_HIER |              |               |
| 1          | END    | PRODUCT_HIER |              |               |

#### Example 84-5 Validating a Hierarchy Without Specifying a Table Name

This example shows that if you do not specify a validation log table, then the `VALIDATE_HIERARCHY` function creates one named `DBMS_HIERARCHY_LOG`.

```
DECLARE
  log_num NUMBER;
  obj_name VARCHAR2(12) := 'PRODUCT_HIER';
BEGIN
  log_num := DBMS_HIERARCHY.VALIDATE_HIERARCHY(obj_name);
END;
```

Query the log table.

```
SELECT LOG_NUMBER, ACTION, OBJECT_NAME, ERROR_NUMBER, ERROR_MESSAGE
FROM DBMS_HIERARCHY_LOG
WHERE OBJECT_NAME = 'PRODUCT_HIER';
```

| LOG_NUMBER | ACTION | OBJECT_NAME  | ERROR_NUMBER | ERROR_MESSAGE |
|------------|--------|--------------|--------------|---------------|
| 1          | START  | PRODUCT_HIER |              |               |
| 1          | END    | PRODUCT_HIER |              |               |

## DBMS\_HM

This package contains constants and procedure declarations for health check management. Health Monitor provides facilities to run a check store and retrieve the reports through `DBMS_HM` package

This chapter contains the following topics:

- [Security Model](#)
- [Summary of DBMS\\_HM Subprograms](#)

### See Also:

*Oracle Database Administrator's Guide* for more information about "Health Monitor"

## 85.1 DBMS\_HM Security Model

Users must have `EXECUTE` privilege to run the procedures of `DBMS_HM` package.

## 85.2 Summary of DBMS\_HM Subprograms

This table lists the `DBMS_CONNECTION_POOL` subprograms and briefly describes them.

**Table 85-1 DBMS\_HM Package Subprograms**

| Subprogram                              | Description                                         |
|-----------------------------------------|-----------------------------------------------------|
| <a href="#">GET_RUN_REPORT Function</a> | Returns the report for the specified checker run    |
| <a href="#">RUN_CHECK Procedure</a>     | Runs the specified checker with the given arguments |

### 85.2.1 GET\_RUN\_REPORT Function

This function returns the report for the specified checker run.

#### Syntax

```
DBMS_HM.GET_RUN_REPORT (  
    run_name      IN  VARCHAR2,  
    type          IN  VARCHAR2 := 'TEXT',  
    level         IN  VARCHAR2 := 'BASIC',  
    RETURN CLOB;
```

## Parameters

**Table 85-2 GET\_RUN\_REPORT Function Parameters**

| Parameter | Description                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------|
| run_name  | Name of the check's run                                                                                         |
| type      | Report format type. Possible values are 'HTML', 'XML' and 'TEXT'. Default report type is 'TEXT'.                |
| level     | Details of report, possible value are 'BASIC' and 'DETAIL'. Caution: Currently only 'BASIC' level is supported. |

## 85.2.2 RUN\_CHECK Procedure

This procedure runs the specified checker with the specified arguments.

You can specify a name for the run, the inputs needed and maximum time-out for the run. The run report will be maintained persistently in the database.

### Syntax

```
DBMS_HM.RUN_CHECK (  
    check_name    IN  VARCHAR2,  
    run_name      IN  VARCHAR2 := NULL,  
    timeout       IN  NUMBER := NULL,  
    input_params  IN  VARCHAR2 := NULL);
```

## Parameters

**Table 85-3 RUN\_CHECK Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| check_name | Name of the check to be invoked. Check names and their parameters can be accessed from the V\$HM_CHECK and V\$HM_CHECK_PARAM views. Users can run all checks which are not internal in nature: <code>SELECT name FROM V\$HM_CHECK WHERE INTERNAL_CHECK = 'N'</code> retrieves the list of checks that can be run manually by users. |
| run_name   | Name with which external users can uniquely identify this check's run. If <code>NULL</code> value is passed, then HM creates a unique name and associates with this check's run.                                                                                                                                                    |
| timeout    | Maximum amount of time (in units of seconds), this checker run is allowed to run. HM will interrupt the run, if it the specified time elapses for the run. If <code>NULL</code> value is passed, HM doesn't impose any timeout limits on the run.                                                                                   |

**Table 85-3 (Cont.) RUN\_CHECK Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input_params | <p>Input string: which consists of name, value pairs de-limited by a special character ';'.<br/>Example ('Data Block Integrity Check' invocation may take following type of input parameters.<br/><br/>'BLC_DF_NUM=1;BLC_BL_NUM=23456'</p> <p>Input parameters BLC_DF_NUM and BLC_BL_NUM have values '1' and '23456' respectively.<br/>Every check will have well defined set of inputs associated with it. These Input parameters, their types, default values and descriptions can be obtained using V\$HM_CHECK_PARAM view.<br/>Example: The following query gets the list of parameters, their default values and descriptions for a 'Data Block Integrity Check'</p> <pre>SELECT a.* FROM v\$hm_check_param a, v\$hm_check b WHERE a.check_id = b.id AND b.name = 'Data Block Integrity Check';</pre> |

## DBMS\_HPROF

The `DBMS_HPROF` package provides an interface for profiling the execution of PL/SQL applications. It provides services for collecting the hierarchical profiler data, analyzing the raw profiler output and profiling information generation.

This chapter contains the following topic:

- [Summary of DBMS\\_HPROF Subprograms](#)

### See Also:

*Oracle Database Development Guide* for more information about the "PL/SQL Hierarchical Profiler"

## 86.1 DBMS\_HPROF Security Model

You must have the following privileges to use the `DBMS_HPROF` package:

- An `EXECUTE` privilege on the `DBMS_HPROF` package.
- A `WRITE` privilege on the directory that you specify when you call the `DBMS_HPROF.START_PROFILING` procedure.

## 86.2 Summary of DBMS\_HPROF Subprograms

This table lists and briefly describes the `DBMS_HPROF` package subprograms.

**Table 86-1 DBMS\_HPROF Package Subprograms**

| Subprogram                                | Description                                                                                         |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">ANALYZE Function</a>          | Analyzes the raw profiler output and produces hierarchical profiler information in database tables. |
| <a href="#">CREATE_TABLES Procedure</a>   | Creates the hierarchical profiler database tables and data structures in the user's session.        |
| <a href="#">START_PROFILING Procedure</a> | Starts hierarchical profiler data collection in the user's session.                                 |
| <a href="#">STOP_PROFILING Procedure</a>  | Stops profiler data collection in the user's session.                                               |

# 86.2.1 ANALYZE Function

This function analyzes the raw profiler output and produces hierarchical profiler information in database tables or generates out-of-the-box HTML reports.

## Syntax

```
DBMS_HPROF.ANALYZE (
    trace_id          IN NUMBER,
    summary_mode      IN BOOLEAN DEFAULT FALSE,
    trace             IN VARCHAR2 DEFAULT NULL,
    skip              IN PLS_INTEGER DEFAULT 0,
    collect           IN PLS_INTEGER DEFAULT NULL,
    run_comment       IN VARCHAR2 DEFAULT NULL)
RETURN NUMBER;

DBMS_HPROF.ANALYZE (
    trace_id          IN NUMBER,
    report_clob       OUT CLOB,
    trace             IN VARCHAR2 DEFAULT NULL,
    skip              IN PLS_INTEGER DEFAULT 0,
    collect           IN PLS_INTEGER DEFAULT NULL);
```

## Parameters

Table 86-2 ANALYZE Function Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trace_id     | The trace_id of the raw profiler data entry in the raw profiler data table (dbmshp_trace_data).                                                                                                                                                                                                                                                                              |
| summary_mode | By default (that is, when summary_mode is FALSE), a detailed analysis is done.<br>When summary_mode is TRUE, only top-level summary information is generated into the database table.                                                                                                                                                                                        |
| report_clob  | The analyzed HTML report.                                                                                                                                                                                                                                                                                                                                                    |
| trace        | Analyzes only the subtrees rooted at the specified trace entry. By default (when trace is NULL), the analysis/reporting is generated for the entire run.<br>The trace entry must be specified in a special quoted qualified format. For example, "HR"."PKG"."FOO" or ""."".__plsql_vm".<br>If multiple overloads exist for the specified name, all of them will be analyzed. |
| skip         | Used only when trace is specified. Analyze only the subtrees rooted at the specified trace, but ignore the first skip invocations to trace.<br>The default value for skip is 0.                                                                                                                                                                                              |
| collect      | Used only when trace is specified.<br>Analyze collect number of invocations of traces (starting from skip+1'th invocation).<br>By default, only 1 invocation is collected.                                                                                                                                                                                                   |
| run_comment  | User-provided comment for this run.                                                                                                                                                                                                                                                                                                                                          |

## Return Values

A unique run identifier for this run of the analyzer. This can then be used to look up the results corresponding to this run from the hierarchical profiler tables.

## Usage Notes

- Use the `DBMS_HPROF.CREATE_TABLES` subprogram to create the hierarchical profiler database tables and other data structures required for persistently storing the results of analyzing the raw profiler data.
- Calling the `DBMS_HPROF.CREATE_TABLES` with default value (`FALSE`) will raise error if table already exists.
- Use `DBMS_HPROF.CREATE_TABLES(TRUE)` to drop any previously created hierarchical profiler tables.
- Use the `DBMS_HPROF.CREATE_TABLES` to drop any previously created hierarchical profiler tables. By default, `force_it` is `FALSE`; therefore, to drop any previously created hierarchical profiler tables you must set the value of `force_it` to `TRUE`.
- If `trace_id` entry is `NULL`, error is raised.
- If `trace_id` entry in the raw profiler data table does not exist, error is raised.
- If raw data of the `trace_id` entry in the raw profiler data table is `NULL` or is zero size, error is raised.

## Examples

The following snippet installs the hierarchical profiler tables in HR schema.

```
connect HR/<password>;
```

The following example analyzes and generates HTML CLOB report from a raw profiler data table.

```
DECLARE
    reportclob clob;
    trace_id number;
BEGIN
    -- create raw profiler data and analysis tables
    -- force_it =>TRUE will dropped the tables if table exists
    DBMS_HPROF.CREATE_TABLES(force_it =>TRUE);

    -- Start profiling
    -- Write raw profiler data in raw profiler data table
    trace_id := DBMS_HPROF.START_PROFILING;

    -- Run procedure to be profiled
    test;

    -- Stop profiling
    DBMS_HPROF.STOP_PROFILING;

    -- analyzes trace_id entry in raw profiler data table and produce
    -- analyzed HTML report in reportclob
    DBMS_HPROF.ANALYZE(trace_id , reportclob);
END;
/
```

## 86.2.2 CREATE\_TABLES Procedure

Creates the hierarchical profiler database tables and data structures in the user's session.

### Syntax

```
DBMS_HPROF.CREATE_TABLES (  
    force_it          IN BOOLEAN DEFAULT FALSE);
```

### Parameters

**Table 86-3 CREATE\_TABLES Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| force_it  | If FALSE and DBMS_HPROF tables are present, then an HPROF error is raised.<br><br>If TRUE, then the procedure creates tables. If the tables already exist, then they are dropped and new tables are created. |

### Note:

Users need not use the `dbmshptab.sql` script located in the `rdbsms/admin` directory to create the hierarchical profiler database tables and data structures anymore.

The `dbmshptab.sql` script is deprecated starting in Oracle Database 18c.

## 86.2.3 START\_PROFILING Procedure

This procedure starts hierarchical profiler data collection in the user's session.

### Syntax

```
DBMS_HPROF.START_PROFILING(  
    max_depth      IN PLS_INTEGER DEFAULT NULL,  
    sqlmonitor     IN BOOLEAN DEFAULT TRUE,  
    run_comment    IN VARCHAR2 DEFAULT NULL)  
RETURN NUMBER;
```

### Parameters

**Table 86-4 START\_PROFILING Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max_depth | By default (that is, when <code>max_depth</code> value is NULL) profile information is gathered for all functions irrespective of their call depth. When a non-NULL value is specified for <code>max_depth</code> , the profiler collects data only for functions up to a call depth level of <code>max_depth</code> . |

**Table 86-4 (Cont.) START\_PROFILING Procedure Parameters**

| Parameter   | Description                                                                                                          |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| sqlmonitor  | Generates a real-time monitoring report for a profiler run when the profiler run ends.<br>The default value is TRUE. |
| run_comment | User provided comment for the profiler data collection run.                                                          |

### Return Values

Unique run identifier for this profiler run. This can then be used to look up the results corresponding to this run from the hierarchical profiler tables.

### Usage Notes

- Even though the profiler does not individually track functions at depth greater than `max_depth`, the time spent in such functions is charged to the ancestor function at depth `max_depth`.
- Raw profiler data is generated in the raw profiler data table with a unique `trace_id`.
- The unique `trace_id` is used to manage the raw profiler output stored in the raw profiler data table.

## 86.2.4 STOP\_PROFILING Procedure

This procedure stops profiler data collection in the user's session. This subprogram also has the side effect of flushing data collected so far in the session, and it signals the end of a run. When the `STOP_PROFILING` procedure returns CLOB, it contains the Real-Time Monitoring report for the profiler run.

### Syntax

```
DBMS_HPROF.STOP_PROFILING;
```

```
DBMS_HPROF.STOP_PROFILING  
RETURN CLOB;
```

### Examples

#### Profiling with raw profiler data table

```
DECLARE  
    analyze_runid number;  
    trace_id number;  
BEGIN  
    -- create raw profiler data and analysis tables  
    -- call create_tables with force_it =>FALSE (default) when  
    -- raw profiler data and analysis tables do not exist already  
    DBMS_HPROF.CREATE_TABLES;  
    -- Start profiling  
    -- Write raw profiler data in raw profiler data table  
    trace_id := DBMS_HPROF.START_PROFILING;  
    -- Run the procedure to be profiled  
    test;  
    -- Stop profiling
```

```
DBMS_HPROF.STOP_PROFILING;  
-- analyzes trace_id entry in raw profiler data table and writes  
-- hierarchical profiler information in hprof's analysis tables  
analyze_runid := DBMS_HPROF.ANALYZE(trace_id);  
END;  
/
```

# DBMS\_HS\_PARALLEL

The `DBMS_HS_PARALLEL` PL/SQL package enables parallel processing for heterogeneous targets access. This package is designed to improve performance when retrieving data from a large foreign table.

This chapter discusses the following topics:

- [Using DBMS\\_HS\\_PARALLEL](#)
- [Summary of DBMS\\_HS\\_PARALLEL Subprograms](#)

## 87.1 Using the DBMS\_HS\_PARALLEL Subprogram

`DBMS_HS_PARALLEL` is compiled with the authorization ID of `CURRENT_USER`, which uses invoker's rights. In other words, all procedures in this package are executed with the privileges of the calling user.

## 87.2 Summary of DBMS\_HS\_PARALLEL Subprograms

This table lists the `DBMS_HS_PARALLEL` subprograms in alphabetic order and briefly describes them.

**Table 87-1 DBMS\_HS\_PARALLEL Package Subprograms**

| Subprogram                             | Description                                                                                                                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_OR_REPLACE_VIEW</a> | Creates (or replaces) a read-only view to be referenced for retrieving the data from a remote table in parallel.                                                                                                               |
| <a href="#">CREATE_TABLE_TEMPLATE</a>  | Writes out a <code>CREATE TABLE</code> template based on information gathered from the remote table. You can use the information to add any optimal Oracle <code>CREATE TABLE</code> clauses.                                  |
| <a href="#">DROP_VIEW</a>              | Drops the view and internal objects created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure. If the view has not already been created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure, an error message is returned. |
| <a href="#">LOAD_TABLE</a>             | Loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.                                                                         |

### 87.2.1 CREATE\_OR\_REPLACE\_VIEW Procedure

This procedure creates (or replaces) a read-only view to be referenced for retrieving the data from a remote table in parallel.

#### Syntax

```
CREATE_OR_REPLACE_VIEW (remote_table, database_link, oracle_view, parallel_degree)
```

## Parameters

**Table 87-2 CREATE\_OR\_REPLACE\_VIEW Procedure Parameters**

| Parameters                   | Description                                                                                                                                                                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>remote_table</code>    | The name of the remote database table. It is specified as <code>[remote_schema_name.]remote_table_name</code> .                                                                                                                                             |
| <code>database_link</code>   | The remote database link name. The call can only be applied to a heterogeneous services database link.                                                                                                                                                      |
| <code>oracle_view</code>     | The name of the Oracle view. It is specified as <code>[schema_name.]oracle_view_name</code> . The default schema name is the current user. If the <code>oracle_view</code> parameter is not specified, the remote table name will be used as the view name. |
| <code>parallel_degree</code> | The number of parallel processes for the operation is computed based on the range-partition number if applicable, or the number of CPUs. The range of values is 2 to 16.                                                                                    |

## Usage Notes

- The specified Oracle view is created and future reference of this view utilizes internal database objects for parallel retrieval of remote non-Oracle table data. If the Oracle view already exists, the following Oracle error message is raised:  
ORA-00955: name is already used by an existing object
- This view is created as a read-only view. If you attempt to insert and update the view, the following Oracle error message is raised:  
ORA-01733: virtual column not allowed here
- If the remote table or the database link does not exist, one of the following Oracle error messages is raised:  
ORA-00942: table or view does not exist  
or  
ORA-02019: connection description for remote database not found
- You need the `CREATE VIEW`, `CREATE TABLE`, `CREATE TYPE`, `CREATE PACKAGE`, and `CREATE FUNCTION` privileges to execute the `CREATE_OR_REPLACE_VIEW` procedure.
- If you encounter either of the following Oracle error messages, increase the `PROCESSES` and `SESSIONS` parameter in the Oracle initialization parameter file:  
ORA-12801: error signaled in parallel query server P003  
or  
ORA-00018: maximum number of session exceeded
- Because the `CREATE_OR_REPLACE_VIEW` procedure creates some internal objects, use the `DROP_VIEW` procedure to drop the view and the internal objects. The `SQL DROP VIEW` statement only drops the view and not the internal objects.

## 87.2.2 CREATE\_TABLE\_TEMPLATE Procedure

This procedure writes out a `CREATE TABLE` template based on information gathered from the remote table. You can use the information to add any optimal Oracle `CREATE TABLE` clauses.

### Syntax

```
CREATE_TABLE_TEMPLATE (remote_table, database_link, oracle_table,
create_table_template_string)
```

### Parameters

**Table 87-3 CREATE\_TABLE\_TEMPLATE Procedure Parameters**

| Parameter                                 | Description                                                                                                                                                                                                                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>remote_table</code>                 | The name of the remote database table. It is specified as <code>[remote_schema_name.]remote_table_name</code> .                                                                                                                                                                                           |
| <code>database_link</code>                | The remote database link name. The call can only be applied to a heterogeneous services database link.                                                                                                                                                                                                    |
| <code>oracle_table</code>                 | The name of the local Oracle table the data will be loaded into. It is specified as <code>[schema_name.]oracle_table_name</code> . The default schema name is the current user. If the <code>oracle_table</code> parameter is not specified, the remote table name will be used as the local Oracle name. |
| <code>create_table_template_string</code> | Contains the Oracle <code>CREATE TABLE</code> SQL template when the procedure is returned.                                                                                                                                                                                                                |

## 87.2.3 DROP\_VIEW Procedure

This procedure drops the view and internal objects created by the `CREATE_OR_REPLACE_VIEW` procedure. If the view has not already been created by the `CREATE_OR_REPLACE_VIEW` procedure, an error message is returned.

### Syntax

```
DROP_VIEW (oracle_view)
```

### Parameters

**Table 87-4 DROP\_VIEW Procedure Parameter**

| Parameter                | Description                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>oracle_view</code> | The name of the Oracle view created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure. If the view has not been created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure, an error is returned. |

## 87.2.4 LOAD\_TABLE Procedure

This procedure loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.

### Syntax

```
LOAD_TABLE (remote_table, database_link, oracle_table, truncate, parallel_degree,
row_count)
```

### Parameters

**Table 87-5 LOAD\_TABLE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| remote_table    | The name of the remote database table. It is specified as [remote_schema_name.]remote_table_name                                                                                                                                                                               |
| database_link   | The remote database link name. The call can only be applied to a heterogeneous services database link.                                                                                                                                                                         |
| oracle_table    | The name of the local Oracle table the data will be loaded into. It is specified as [schema_name.]oracle_table_name. The default schema name is the current user. If the oracle_table parameter is not specified, the remote table name will be used as the local Oracle name. |
| truncate        | Determines whether the Oracle table is truncated before the data is loaded. The value is either TRUE or FALSE. The default value is TRUE which means the Oracle table is truncated first. When set to FALSE, the Oracle table will not be truncated before the data is loaded. |
| parallel_degree | The number of parallel processes for the operation is computed based on the range-partition number if applicable, or the number of CPUs. The range of values is 2 to 16.                                                                                                       |
| row_count       | Contains the number of rows just added with the load table operation.                                                                                                                                                                                                          |

### Usage Notes

- This procedure only loads the remote table data into Oracle local table. It does not create a key, index, constraints or any other dependencies such as triggers. It is recommended that you create these dependencies after the table data is loaded as performance will improve greatly. You will need to decide whether to create the dependencies before or after the data is loaded based on your knowledge of the remote table data and dependencies.
- If the local table does not exist, the LOAD\_TABLE procedure creates a simple (non-partitioned) local table based on the exact column matching of the remote table after which the data is inserted into the local table.
- If the remote table or the database link does not exist, an error message is returned.
- If the local table is incompatible with the remote table, an error message is returned.
- You need the CREATE TABLE, CREATE TYPE, CREATE PACKAGE, and CREATE FUNCTION privileges to execute the LOAD\_TABLE procedure.

- If you encounter either of the following Oracle error messages, increase the `PROCESSES` and `SESSIONS` parameter in Oracle initialization parameter file:  
  
`ORA-12801: error signaled in parallel query server P003`  
`or`  
`ORA-00018: maximum number of session exceeded`
- One of the following is required for parallel processing:
  - The remote table is range partitioned.
  - Histogram information for a numeric column is available.
  - There is a numeric index or primary key.
- To drop the local table, use the `DROP TABLE` SQL statement.

# DBMS\_HS\_PASSTHROUGH

The `DBMS_HS_PASSTHROUGH` PL/SQL package allows you to send a statement directly to a non-Oracle system without being interpreted by the Oracle server. This can be useful if the non-Oracle system allows operations in statements for which there is no equivalent in Oracle.

This chapter discusses the following topics:

- [DBMS\\_HS\\_PASSTHROUGH Overview](#)
- [DBMS\\_HS\\_PASSTHROUGH Operational Notes](#)
- [Summary of DBMS\\_HS\\_PASSTHROUGH Subprograms](#)

## See Also:

*Oracle Database Heterogeneous Connectivity User's Guide* for more information about this package

## 88.1 DBMS\_HS\_PASSTHROUGH Overview

You can execute passthrough SQL statements directly at the non-Oracle system using the PL/SQL package `DBMS_HS_PASSTHROUGH`. Any statement executed with this package is executed in the same transaction as standard SQL statements.

## See Also:

*Oracle Database Heterogeneous Connectivity User's Guide* for information about this package

## 88.2 DBMS\_HS\_PASSTHROUGH Operational Notes

The `DBMS_HS_PASSTHROUGH` package is a virtual package. It conceptually resides at the non-Oracle system. In reality, however, calls to this package are intercepted by Heterogeneous Services and mapped to one or more Heterogeneous Services calls. The driver, in turn, maps these Heterogeneous Services calls to the API of the non-Oracle system. The client application should invoke the procedures in the package through a database link in exactly the same way as it would invoke a non-Oracle system stored procedure. The special processing done by Heterogeneous Services is transparent to the user.

## 88.3 Summary of DBMS\_HS\_PASSTHROUGH Subprograms

This table lists the `DBMS_HS_PASSTHROUGH` subprograms and briefly describes them.

**Table 88-1 DBMS\_HS\_PASSTHROUGH Package Subprograms**

| Subprogram                                        | Description                                                                                                    |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">BIND_INOUT_VARIABLE Procedure</a>     | Binds IN OUT bind variables                                                                                    |
| <a href="#">BIND_INOUT_VARIABLE_RAW Procedure</a> | Binds IN OUT bind variables of datatype RAW                                                                    |
| <a href="#">BIND_OUT_VARIABLE Procedure</a>       | Binds an OUT variable with a PL/SQL program variable                                                           |
| <a href="#">BIND_OUT_VARIABLE_RAW Procedure</a>   | Binds an OUT variable of datatype RAW with a PL/SQL program variable                                           |
| <a href="#">BIND_VARIABLE Procedure</a>           | Binds an IN variable positionally with a PL/SQL program variable                                               |
| <a href="#">BIND_VARIABLE_RAW Procedure</a>       | Binds IN variables of type RAW                                                                                 |
| <a href="#">CLOSE_CURSOR Procedure</a>            | Closes the cursor and releases associated memory after the SQL statement has been run at the non-Oracle system |
| <a href="#">EXECUTE_IMMEDIATE Procedure</a>       | Runs a (non-SELECT) SQL statement immediately, without bind variables                                          |
| <a href="#">EXECUTE_NON_QUERY Function</a>        | Runs a (non-SELECT) SQL statement                                                                              |
| <a href="#">FETCH_ROW Function</a>                | Fetches rows from a query                                                                                      |
| <a href="#">GET_VALUE Procedure</a>               | Retrieves column value from SELECT statement, or retrieves OUT bind parameters                                 |
| <a href="#">GET_VALUE_RAW Procedure</a>           | Similar to GET_VALUE, but for datatype RAW                                                                     |
| <a href="#">OPEN_CURSOR Function</a>              | Opens a cursor for running a passthrough SQL statement at the non-Oracle system                                |
| <a href="#">PARSE Procedure</a>                   | Parses SQL statement at non-Oracle system                                                                      |

### 88.3.1 BIND\_INOUT\_VARIABLE Procedure

This procedure binds IN OUT bind variables.

#### Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE (
  c      IN  BINARY_INTEGER NOT NULL,
  p      IN  BINARY_INTEGER NULL,
  v      OUT <dt>,
  n      IN  VARCHAR2);
```

<dt> is either DATE, NUMBER, or VARCHAR2.

#### See Also:

For binding OUT variables of datatype RAW, see [BIND\\_OUT\\_VARIABLE\\_RAW Procedure](#).

#### Pragmas

Purity level defined : WNDS, RNDS

## Parameters

**Table 88-2 BIND\_INOUT\_VARIABLE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                   |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                           |
| v         | This value is used for two purposes:<br>- To provide the IN value before the SQL statement is run.<br>- To determine the size of the out value.                                                                                                                                                                                                            |
| n         | (Optional) Name of the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required. |

## Exceptions

**Table 88-3 BIND\_INOUT\_VARIABLE Procedure Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28553 | The position of the bind variable is out of range.                                                |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter.                                                 |

## 88.3.2 BIND\_INOUT\_VARIABLE\_RAW Procedure

This procedure binds IN OUT bind variables of datatype RAW.

### Syntax

```
DBMS_HS_PASSTHROUGH.BIND_INOUT_VARIABLE_RAW (
    c      IN      BINARY_INTEGER NOT NULL,
    p      IN      BINARY_INTEGER NOT NULL,
    v      IN OUT  RAW,
    n      IN      VARCHAR2);
```

### Pragmas

Purity level defined : WNDS, RNDS

## Parameters

**Table 88-4 BIND\_INOUT\_VARIABLE\_RAW Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                 |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                        |
| v         | This value is used for two purposes:<br>- To provide the IN value before the SQL statement is run.<br>- To determine the size of the out value.                                                                                                                                                                                                         |
| n         | (Optional) Name the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required. |

## Exceptions

**Table 88-5 BIND\_INOUT\_VARIABLE\_RAW Procedure Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28553 | The position of the bind variable is out of range.                                                |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter.                                                 |

## 88.3.3 BIND\_OUT\_VARIABLE Procedure

This procedure binds an `OUT` variable with a PL/SQL program variable.

### Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE (
  c      IN  BINARY_INTEGER NOT NULL,
  p      IN  BINARY_INTEGER NULL,
  v      OUT <dt>,
  n      IN  VARCHAR2);
```

<dt> is either DATE, NUMBER, or VARCHAR2.

### See Also:

For binding `OUT` variables of datatype `RAW`, see [BIND\\_OUT\\_VARIABLE\\_RAW Procedure](#).

## Parameters

**Table 88-6 BIND\_OUT\_VARIABLE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                                                     |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                                                             |
| v         | Variable in which the <code>OUT</code> bind variable stores its value. The package remembers only the "size" of the variable. After the SQL statement is run, you can use <code>GET_VALUE</code> to retrieve the value of the <code>OUT</code> parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using <code>BIND_OUT_VARIABLE</code> . |
| n         | (Optional) Name of the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.                                   |

## Exceptions

**Table 88-7 BIND\_OUT\_VARIABLE Procedure Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28553 | The position of the bind variable is out of range.                                                |
| ORA-28555 | A <code>NULL</code> value was passed for a <code>NOT NULL</code> parameter.                       |

## 88.3.4 BIND\_OUT\_VARIABLE\_RAW Procedure

This procedure binds an `OUT` variable of datatype `RAW` with a PL/SQL program variable.

### Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE_RAW (
    c      IN  BINARY_INTEGER NOT NULL,
    p      IN  BINARY_INTEGER NOT NULL,
    v      OUT RAW,
    n      IN  VARCHAR2);
```

### Pragmas

Purity level defined : WNDS, RNDS

## Parameters

**Table 88-8 BIND\_OUT\_VARIABLE\_RAW Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                                                         |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                                                                 |
| v         | Variable in which the <code>OUT</code> bind variable stores its value. The package remembers only the "size" of the variable. After the SQL statement is run, you can use <code>GET_VALUE</code> to retrieve the value of the <code>OUT</code> parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using <code>BIND_OUT_VARIABLE_RAW</code> . |
| n         | (Optional) Name of the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.                                       |

## Exceptions

**Table 88-9 BIND\_OUT\_VARIABLE\_RAW Procedure Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28553 | The position of the bind variable is out of range.                                                |
| ORA-28555 | A <code>NULL</code> value was passed for a <code>NOT NULL</code> parameter.                       |

## 88.3.5 BIND\_VARIABLE Procedure

This procedure binds an `IN` variable positionally with a PL/SQL program variable.

### Syntax

```
DBMS_HS_PASSTHROUGH.BIND_VARIABLE (
  c      IN BINARY_INTEGER NOT NULL,
  p      IN BINARY_INTEGER NOT NULL,
  v      IN <dt>,
  n      IN VARCHAR2);
```

<dt> is either `DATE`, `NUMBER`, or `VARCHAR2`.

### See Also:

To bind `RAW` variables use [BIND\\_VARIABLE\\_RAW Procedure](#).

## Pragmas

Purity level defined: WNDS, RNDS

## Parameters

**Table 88-10 BIND\_VARIABLE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                    |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                           |
| v         | Value that must be passed to the bind variable name.                                                                                                                                                                                                                                                                                                       |
| n         | (Optional) Name of the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required. |

## Exceptions

## Parameters

**Table 88-12 BIND\_VARIABLE\_RAW Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                                                                   |
| p         | Position of the bind variable in the SQL statement: Starts at 1.                                                                                                                                                                                                                                                                                           |
| v         | Value that must be passed to the bind variable.                                                                                                                                                                                                                                                                                                            |
| n         | (Optional) Name of the bind variable.<br>For example, in <code>SELECT * FROM emp WHERE ename=:ename</code> , the position of the bind variable <code>:ename</code> is 1, the name is <code>:ename</code> . This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required. |

## Exceptions

**Table 88-13 BIND\_VARIABLE\_RAW Procedure Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28553 | The position of the bind variable is out of range.                                                |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter.                                                 |

## 88.3.7 CLOSE\_CURSOR Procedure

This function closes the cursor and releases associated memory after the SQL statement has been run at the non-Oracle system. If the cursor was not open, then the operation is a "no operation".

### Syntax

```
DBMS_HS_PASSTHROUGH.CLOSE_CURSOR (
    c IN BINARY_INTEGER NOT NULL);
```

### Pragmas

Purity level defined : WNDS, RNDS

## Parameters

**Table 88-14 CLOSE\_CURSOR Procedure Parameters**

| Parameter | Description            |
|-----------|------------------------|
| c         | Cursor to be released. |

## Exceptions

**Table 88-15** CLOSE\_CURSOR Procedure Exceptions

| Exception | Description                                       |
|-----------|---------------------------------------------------|
| ORA-28555 | A NULL value was passed for a NOT NULL parameter. |

## 88.3.8 EXECUTE\_IMMEDIATE Procedure

This function runs a SQL statement immediately. Any valid SQL command except `SELECT` can be run immediately.

The statement must not contain any bind variables. The statement is passed in as a `VARCHAR2` in the argument. Internally the SQL statement is run using the `PASSTHROUGH` SQL protocol sequence of `OPEN_CURSOR`, `PARSE`, `EXECUTE_NON_QUERY`, `CLOSE_CURSOR`.

### Syntax

```
DBMS_HS_PASSTHROUGH.EXECUTE_IMMEDIATE (  
    s IN VARCHAR2 NOT NULL)  
RETURN BINARY_INTEGER;
```

### Parameters

**Table 88-16** EXECUTE\_IMMEDIATE Procedure Parameters

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| s         | VARCHAR2 variable with the statement to be executed immediately. |

### Return Values

The number of rows affected by the execution of the SQL statement.

## Exceptions

**Table 88-17** EXECUTE\_IMMEDIATE Procedure Exceptions

| Exception | Description                                       |
|-----------|---------------------------------------------------|
| ORA-28551 | SQL statement is invalid.                         |
| ORA-28554 | Max open cursors.                                 |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter. |

## 88.3.9 EXECUTE\_NON\_QUERY Function

This function runs a SQL statement. The SQL statement cannot be a `SELECT` statement. A cursor has to be open and the SQL statement has to be parsed before the SQL statement can be run.

### Syntax

```
DBMS_HS_PASSTHROUGH.EXECUTE_NON_QUERY (
    c IN BINARY_INTEGER NOT NULL)
RETURN BINARY_INTEGER;
```

### Parameters

**Table 88-18 EXECUTE\_NON\_QUERY Function Parameters**

| Parameter | Description                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively. |

### Return Values

The number of rows affected by the SQL statement in the non-Oracle system

### Exceptions

**Table 88-19 EXECUTE\_NON\_QUERY Function Exceptions**

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter.                                                 |

## 88.3.10 FETCH\_ROW Function

This function fetches rows from a result set.

The result set is defined with a SQL `SELECT` statement. When there are no more rows to be fetched, the exception `NO_DATA_FOUND` is raised. Before the rows can be fetched, a cursor has to be opened, and the SQL statement has to be parsed.

### Syntax

```
DBMS_HS_PASSTHROUGH.FETCH_ROW (
    c IN BINARY_INTEGER NOT NULL,
    f IN BOOLEAN)
RETURN BINARY_INTEGER;
```

### Pragmas

Purity level defined : WNDS

## Parameters

**Table 88-20** FETCH\_ROW Function Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.                                                                                                                                      |
| first     | (Optional) Reexecutes <code>SELECT</code> statement. Possible values: <ul style="list-style-type: none"> <li>- <code>TRUE</code>: reexecute <code>SELECT</code> statement.</li> <li>- <code>FALSE</code>: fetch the next row, or if run for the first time, then execute and fetch rows (default).</li> </ul> |

## Return Values

The returns the number of rows fetched. The function returns "0" if the last row was already fetched.

## Exceptions

**Table 88-21** FETCH\_ROW Function Exceptions

| Exception | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                                                                     |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?) |
| ORA-28555 | A <code>NULL</code> value was passed for a <code>NOT NULL</code> parameter.                       |

## 88.3.11 GET\_VALUE Procedure

This procedure has two purposes: it retrieves the select list items of `SELECT` statements after a row has been fetched, and it retrieves the `OUT` bind values, after the SQL statement has been run.

### Syntax

```
DBMS_HS_PASSTHROUGH.GET_VALUE (
  c      IN BINARY_INTEGER NOT NULL,
  p      IN BINARY_INTEGER NOT NULL,
  v      OUT <dt>);
```

<dt> is either `DATE`, `NUMBER`, or `VARCHAR2`.

### See Also:

For retrieving values of datatype `RAW`, see [GET\\_VALUE\\_RAW Procedure](#).

### Pragmas

Purity level defined : `WNS`

## Parameters

**Table 88-22 GET\_VALUE Procedure Parameters**

| Parameter | Description                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively. |
| p         | Position of the bind variable or select list item in the SQL statement: Starts at 1.                                                                                     |
| v         | Variable in which the <code>OUT</code> bind variable or select list item stores its value.                                                                               |

## Exceptions

**Table 88-23 GET\_VALUE Procedure Exceptions**

| Exception | Description                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-1403  | Returns <code>NO_DATA_FOUND</code> exception when running the <code>GET_VALUE</code> after the last row was fetched (that is, <code>FETCH_ROW</code> returned "0"). |
| ORA-28550 | The cursor passed is invalid.                                                                                                                                       |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)                                                                   |
| ORA-28553 | The position of the bind variable is out of range.                                                                                                                  |
| ORA-28555 | A <code>NULL</code> value was passed for a <code>NOT NULL</code> parameter.                                                                                         |

## 88.3.12 GET\_VALUE\_RAW Procedure

This procedure is similar to `GET_VALUE`, but for datatype `RAW`.

### Syntax

```
DBMS_HS_PASSTHROUGH.GET_VALUE_RAW (
    c    IN  BINARY_INTEGER NOT NULL,
    p    IN  BINARY_INTEGER NOT NULL,
    v    OUT RAW);
```

### Pragmas

Purity level defined : WNDS

## Parameters

**Table 88-24 GET\_VALUE\_RAW Procedure Parameters**

| Parameter | Description                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively. |

**Table 88-24 (Cont.) GET\_VALUE\_RAW Procedure Parameters**

| Parameter | Description                                                                          |
|-----------|--------------------------------------------------------------------------------------|
| p         | Position of the bind variable or select list item in the SQL statement: Starts at 1. |
| v         | Variable in which the OUT bind variable or select list item stores its value.        |

### Exceptions

**Table 88-25 GET\_VALUE\_RAW Procedure Exceptions**

| Exception | Description                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------|
| ORA-1403  | Returns NO_DATA_FOUND exception when running the GET_VALUE after the last row was fetched (that is, FETCH_ROW returned "0"). |
| ORA-28550 | The cursor passed is invalid.                                                                                                |
| ORA-28552 | Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)                            |
| ORA-28553 | The position of the bind variable is out of range.                                                                           |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter.                                                                            |

## 88.3.13 OPEN\_CURSOR Function

This function opens a cursor for running a passthrough SQL statement at the non-Oracle system. This function must be called for any type of SQL statement.

The function returns a cursor, which must be used in subsequent calls. This call allocates memory. To deallocate the associated memory, call the procedure CLOSE\_CURSOR.

### Syntax

```
DBMS_HS_PASSTHROUGH.OPEN_CURSOR  
RETURN BINARY_INTEGER;
```

### Pragmas

Purity level defined : WNDS, RNDS

### Return Values

The cursor to be used on subsequent procedure and function calls.

### Exceptions

**Table 88-26 OPEN\_CURSOR Function Exceptions**

| Exception | Description                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------|
| ORA-28554 | Maximum number of open cursor has been exceeded. Increase Heterogeneous Services' OPEN_CURSORS initialization parameter. |

## 88.3.14 PARSE Procedure

This procedure parses an SQL statement at a non-Oracle system.

### Syntax

```
DBMS_HS_PASSTHROUGH.PARSE (
    c          IN  BINARY_INTEGER NOT NULL,
    stmt       IN  VARCHAR2 NOT NULL);
```

### Pragmas

Purity level defined : WNDS, RNDS

### Parameters

**Table 88-27 PARSE Procedure Parameters**

| Parameter | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| c         | Cursor associated with the passthrough SQL statement. Cursor must be opened using function <code>OPEN_CURSOR</code> . |
| stmt      | Statement to be parsed.                                                                                               |

### Exceptions

**Table 88-28 PARSE Procedure Exceptions**

| Exception | Description                                       |
|-----------|---------------------------------------------------|
| ORA-28550 | The cursor passed is invalid.                     |
| ORA-28551 | SQL statement is illegal.                         |
| ORA-28555 | A NULL value was passed for a NOT NULL parameter. |

# DBMS\_ILM

The `DBMS_ILM` package provides an interface for implementing Information Lifecycle Management (ILM) strategies using Automatic Data Optimization (ADO) policies.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Exceptions](#)
- [Summary of DBMS\\_ILM Subprograms](#)

## See Also:

- *Oracle Database VLDB and Partitioning Guide* for information about managing Automatic Data Optimization (ADO) with this package
- [DBMS\\_ILM\\_ADMIN](#)
- [DBMS\\_HEAT\\_MAP](#)

## 89.1 DBMS\_ILM Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database. The `DBMS_ILM` package supports immediate evaluation or execution of ADO related tasks. The

he package supports the following two ways for scheduling ADO actions.

- A database user schedules immediate ADO policy execution on a set of objects.
- A database user views the results of evaluation of ADO policies on a set of objects. The user then adds or deletes objects to this set and reviews the results of ADO policy evaluation again. The user repeats this step to determine the set of objects for ADO execution. The user can then schedule ADO actions for immediate execution on this set of objects.

The following procedures support the two usage modes. Before describing the procedures, we introduce the notion of an ADO task as an entity that helps to track a particular evaluation or (an evaluation and execution) of ADO policies. A particular ADO task could be in one of the following states.

- Inactive
- Active
- Completed

## 89.2 DBMS\_ILM Security Model

The DBMS\_ILM package runs under invoker's rights.

## 89.3 DBMS\_ILM Constants

The table in this topic lists the constants used by the DBMS\_ILM package.

**Table 89-1 DBMS\_ILM Constants**

| Constant               | Value             | Type          | Description                                                                                                           |
|------------------------|-------------------|---------------|-----------------------------------------------------------------------------------------------------------------------|
| ILM_ALL_POLICIES       | 'ALL<br>POLICIES' | VARCHAR2 (20) | Selects all ADO policies on an object                                                                                 |
| ILM_EXECUTION_OFFLINE  | 1                 | NUMBER        | Specifies that the object may be offline while ADO action is performed                                                |
| ILM_EXECUTION_ONLINE   | 2                 | NUMBER        | Specifies that the object should be online while ADO action is performed                                              |
| SCOPE_DATABASE         | 1                 | NUMBER        | Selects all ADO policies in the database                                                                              |
| SCOPE_SCHEMA           | 2                 | NUMBER        | Selects all ADO policies in the current schema                                                                        |
| SCHEDULE_IMMEDIATE     | 1                 | NUMBER        | Schedules ADO task for immediate execution                                                                            |
| ARCHIVE_STATE_ACTIVE   | '0'               | VARCHAR2 (1)  | Represents the value of the ORA_ARCHIVE_STATE column of a row-archival enabled table that would make the row active   |
| ARCHIVE_STATE_INACTIVE | '1'               | VARCHAR2 (1)  | Represents the value of the ORA_ARCHIVE_STATE column of a row-archival enabled table that would make the row inactive |

## 89.4 DBMS\_ILM Exceptions

The table in this topic lists the exceptions raised by the DBMS\_ILM package.

**Table 89-2 DBMS\_ILM Exceptions**

| Exception               | Error Code | Description                   |
|-------------------------|------------|-------------------------------|
| INVALID_ARGUMENT_VALUE  | 38327      | Invalid argument value        |
| INVALID_ILM_DICTIONARY  | 38328      | Inconsistent dictionary state |
| INTERNAL_ILM_ERROR      | 38329      | Internal error                |
| INSUFFICIENT_PRIVILEGES | 38330      | Insufficient privileges       |

## 89.5 Summary of DBMS\_ILM Subprograms

This table lists and describes the DBMS\_ILM package subprograms.

**Table 89-3 DBMS\_ILM Package Subprograms**

| Subprogram                                 | Description                                                                                                           |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_TO_ILM Procedure</a>       | Adds the object specified through the argument to a particular ADO task and evaluates the ADO policies on this object |
| <a href="#">ARCHIVESTATENAME Function</a>  | Returns the value of the <code>ORA_ARCHIVE_STATE</code> column of a row-archival enabled table                        |
| <a href="#">EXECUTE_ILM Procedure</a>      | Executes an ADO task.                                                                                                 |
| <a href="#">EXECUTE_ILM_TASK Procedure</a> | Executes an ADO task that has been evaluated previously                                                               |
| <a href="#">PREVIEW_ILM Procedure</a>      | Evaluates all ADO policies in the scope specified by means of an argument                                             |
| <a href="#">REMOVE_FROM_ILM Procedure</a>  | Removes the object specified through the argument from a particular ADO task                                          |
| <a href="#">STOP_ILM Procedure</a>         | Stops ADO-related jobs created for a particular ADO task                                                              |

### 89.5.1 ADD\_TO\_ILM Procedure

This procedure adds the object specified through the argument to a particular ADO task and evaluates the ADO policies on this object.

The procedure can only be executed on an ADO task in an inactive state. The results of the ADO policy evaluation on this object can be viewed using the appropriate views depending on role and access (`USER_ILMTASKS` or `DBA_ILMTASKS`, `USER_ILMEVALUATIONDETAILS` or `DBA_ILMEVALUATIONDETAILS`, `USER_ILMRESULTS` or `DBA_ILMRESULTS`).

#### Syntax

```
DBMS_ILM.ADD_TO_ILM (  
    task_id           IN    NUMBER,  
    owner             IN    VARCHAR2,  
    object_name       IN    VARCHAR2,  
    subobject_name    IN    VARCHAR2 DEFAULT NULL);
```

#### Parameters

**Table 89-4 ADD\_TO\_ILM Procedure Parameters**

| Parameter                   | Description                                                              |
|-----------------------------|--------------------------------------------------------------------------|
| <code>task_id</code>        | Identifies a particular ADO task                                         |
| <code>owner</code>          | Owner of the object                                                      |
| <code>object_name</code>    | Name of the object                                                       |
| <code>subobject_name</code> | Name of the subobject (partition name in the case of partitioned tables) |

## 89.5.2 ARCHIVESTATENAME Function

This function returns the value of the `ORA_ARCHIVE_STATE` column of a row-archival enabled table.

### Syntax

```
DBMS_ILM.ARCHIVESTATENAME (
    value      IN  VARCHAR2)
RETURN VARCHAR2;
```

### Parameters

**Table 89-5** *ARCHIVESTATENAME Function Parameters*

| Parameter | Description                                              |
|-----------|----------------------------------------------------------|
| value     | Value for which the archive state name is to be returned |

### Usage Notes

Returns `ARCHIVE_STATE_ACTIVE` for 0, `ARCHIVE_STATE_ARCHIVED` for others

#### See Also:

"Using In-Database Archiving" in *Oracle Database VLDB and Partitioning Guide*

## 89.5.3 EXECUTE\_ILM Procedure

This procedure executes an ADO task.

There are two overloads to this procedure. The first overload executes an ADO task for a set of objects without having evaluated them previously. The second overload executes ADO policies for a specific object.

### Syntax

```
DBMS_ILM.EXECUTE_ILM (
    task_id      OUT  NUMBER,
    ilm_scope    IN    NUMBER DEFAULT SCOPE_SCHEMA,
    execution_mode IN  NUMBER DEFAULT ILM_EXECUTION_ONLINE);

DBMS_ILM.EXECUTE_ILM (
    owner        IN  VARCHAR2,
    object_name  IN  VARCHAR2,
    task_id      OUT  NUMBER,
    subobject_name IN VARCHAR2 DEFAULT NULL,
    policy_name  IN  VARCHAR2 DEFAULT ILM_ALL_POLICIES,
    execution_mode IN  NUMBER DEFAULT ILM_EXECUTION_ONLINE);
```

## Parameters

**Table 89-6 EXECUTE\_ILM Procedure Parameters**

| Parameter      | Description                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| task_id        | Identifies a particular ADO task                                                                                                                                 |
| ilm_scope      | Determines the set of objects considered for ADO execution. The default is to consider only the objects in the schema.                                           |
| execution_mode | Whether the ADO task be executed online (ILM_EXECUTION_ONLINE) or offline (ILM_EXECUTION_OFFLINE)                                                                |
| owner          | Owner of the object                                                                                                                                              |
| object_name    | Name of the object                                                                                                                                               |
| subobject_name | Name of the subobject (partition name in the case of partitioned tables)                                                                                         |
| policy_name    | Name of the ADO policy to be evaluated on the object. The package constant ILM_ALL_POLICIES should be used if all ADO policies on an object should be evaluated. |

## Usage Notes

- The EXECUTE\_ILM procedure can be used by users who want more control of when ADO is performed, and who do not want to wait until the next maintenance window.
- The procedure executes like a DDL in that it auto commits before and after the ADO task and related jobs are created.

## 89.5.4 EXECUTE\_ILM\_TASK Procedure

This procedure executes an ADO task that has been evaluated previously and moves it to an active state.

## Syntax

```
DBMS_ILM.EXECUTE_ILM_TASK (  
    task_id          IN      NUMBER,  
    execution_mode    IN      NUMBER DEFAULT ILM_EXECUTION_ONLINE);  
    execution_schedule IN      NUMBER DEFAULT SCHEDULE_IMMEDIATE);
```

## Parameters

**Table 89-7 EXECUTE\_ILM\_TASK Procedure Parameters**

| Parameter          | Description                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| task_id            | Identifies a particular ADO task                                                                                          |
| execution_mode     | Whether the ADO task be executed online (ILM_EXECUTION_ONLINE) or offline (ILM_EXECUTION_OFFLINE)                         |
| execution_schedule | Identifies when the ADO task should be executed. Currently, the only choice available is immediate scheduling of ADO jobs |

## 89.5.5 PREVIEW\_ILM Procedure

This procedure evaluates the ADO policies on the objects specified using the `ILM_SCOPE` argument.

It returns a number as `task_id` which identifies a particular ADO task. This can be used to view the results of the policy evaluation in the appropriate views depending on role and access (`USER_ILMTASKS` or `DBA_ILMTASKS`, `USER_ILMEVALUATIONDETAILS` or `DBA_ILMEVALUATIONDETAILS`, `USER_ILMRESULTS` or `DBA_ILMRESULTS`).

The `PREVIEW_ILM` procedure leaves the ADO task in an inactive state. Once you have previewed the results, you can add or delete objects to this task.

### Syntax

```
DBMS_ILM.PREVIEW_ILM (  
    task_id      OUT      NUMBER,  
    ilm_scope     IN       NUMBER DEFAULT SCOPE_SCHEMA);
```

### Parameters

**Table 89-8** *PREVIEW\_ILM Procedure Parameters*

| Parameter              | Description                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>task_id</code>   | Identifies a particular ADO task                                                                                                                       |
| <code>ilm_scope</code> | Identifies the scope of execution. Should be either <code>SCOPE_DATABASE</code> or <code>SCOPE_SCHEMA</code> as described in <a href="#">Constants</a> |

## 89.5.6 REMOVE\_FROM\_ILM Procedure

This procedure removes the object specified through the argument from a particular ADO task.

The procedure can only be executed on an ADO task in an inactive state.

### Syntax

```
DBMS_ILM.REMOVE_FROM_ILM (  
    task_id      IN      NUMBER,  
    owner         IN      VARCHAR2,  
    object_name   IN      VARCHAR2,  
    subobject_name IN     VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 89-9** *REMOVE\_FROM\_ILM Procedure Parameters*

| Parameter                   | Description                                                              |
|-----------------------------|--------------------------------------------------------------------------|
| <code>task_id</code>        | Identifies a particular ADO task                                         |
| <code>owner</code>          | Owner of the object                                                      |
| <code>object_name</code>    | Name of the object                                                       |
| <code>subobject_name</code> | Name of the subobject (partition name in the case of partitioned tables) |

## 89.5.7 STOP\_ILM Procedure

This procedure terminates ILM ADO jobs associated to a particular task Id or job name.

### Syntax

```
DBMS_ILM.STOP_ILM (
    task_id          IN          NUMBER,
    p_drop_running_jobs  IN          BOOLEAN  DEFAULT FALSE),
    p_jobname        IN          VARCHAR2  DEFAULT NULL);
```

### Parameters

**Table 89-10** *STOP\_ILM Procedure Parameters*

| Parameter           | Description                                           |
|---------------------|-------------------------------------------------------|
| task_id             | Number that uniquely identifies a particular ADO task |
| p_drop_running_jobs | Determines whether running jobs are dropped           |
| p_jobname           | Name of job to be terminated                          |

# DBMS\_ILM\_ADMIN

The `DBMS_ILM_ADMIN` package provides an interface to customize Automatic Data Optimization (ADO) policy execution. In combination with partitioning and compression, ADO policies can be used to help implement an Information Lifecycle Management (ILM) strategy.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_ILM\\_ADMIN Subprograms](#)

**See Also:**

- *Oracle Database VLDB and Partitioning Guide* for information about managing Automatic Data Optimization (ADO) with this package
- [DBMS\\_ILM](#)
- [DBMS\\_HEAT\\_MAP](#)

## 90.1 DBMS\_ILM\_ADMIN Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database.

## 90.2 DBMS\_ILM\_ADMIN Security Model

This package runs under definer's rights. The user requires DBA privileges.

## 90.3 DBMS\_ILM\_ADMIN Constants

The table in this topic describes constants used by the `DBMS_ILM_ADMIN` package.

The value column refers to the numeric or character value that the constants resolve to.

**Table 90-1 DBMS\_ILM\_ADMIN Constants**

| Constant                  | Value | Type   | Description                                               |
|---------------------------|-------|--------|-----------------------------------------------------------|
| <code>ABS_JOBLIMIT</code> | 12    | NUMBER | Specifies the absolute number of concurrent ILM ADO jobs. |

**Table 90-1 (Cont.) DBMS\_ILM\_ADMIN Constants**

| Constant            | Value | Type   | Description                                                                                                                                                                                                                    |
|---------------------|-------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXECUTION_INTERVAL  | 1     | NUMBER | Determines the frequency with which ADO background evaluation occurs. Specified in minutes.                                                                                                                                    |
| RETENTION_TIME      | 2     | NUMBER | Controls the amount of time ADO history should be maintained. Specified in days.                                                                                                                                               |
| EXECUTION_MODE      | 4     | NUMBER | Controls whether ADO execution is online, offline. The value for this parameter should either be<br>DBMS_ILM_ADMIN.ILM_EXECUTION_OFFLINE<br>or<br>DBMS_ILM_ADMIN.ILM_EXECUTION_ONLINE.                                         |
| JOBLIMIT            | 5     | NUMBER | Controls the upper limit on number of ILM ADO jobs at any time. The maximum number of concurrent ADO jobs is JOBLIMIT*(number of instances)*(number of CPUs per instance).                                                     |
| JOB_SIZELIMIT       | 13    | NUMBER | Specifies the size (in megabytes) of the data that is processed by a single ILM ADO row level compression job.                                                                                                                 |
| ENABLED             | 7     | NUMBER | Provides a way to turn background ADO off or on                                                                                                                                                                                |
| TBS_PERCENT_USED    | 8     | NUMBER | Decides when a tablespace is considered full. Specified as a percentage of tablespace quota.                                                                                                                                   |
| TBS_PERCENT_FREE    | 9     | NUMBER | Decides the targeted tablespace storage through ADO actions as a percentage of tablespace quota.                                                                                                                               |
| DEG_PARALLEL        | 10    | NUMBER | Decides the degree of parallelism to be used for ADO jobs                                                                                                                                                                      |
| POLICY_TIME         | 11    | NUMBER | Decides if ADO policies are treated as though they are specified in seconds rather than days. Can take value ILM_POLICY_IN_SECONDS (treat policy time in seconds) or ILM_POLICY_IN_DAYS (treat policy time in days - default). |
| HEAT_MAP_SEG_READ   | 1     | NUMBER | Segment read done                                                                                                                                                                                                              |
| HEAT_MAP_SEG_WRITE  | 2     | NUMBER | Segment write done                                                                                                                                                                                                             |
| HEAT_MAP_SEG_SCAN   | 4     | NUMBER | Full table scan done                                                                                                                                                                                                           |
| HEAT_MAP_SEG_LOOKUP | 8     | NUMBER | Index scan done                                                                                                                                                                                                                |

The DBMS\_ILM\_ADMIN package uses the constants as parameter values shown in [Table 90-2](#).

**Table 90-2 DBMS\_ILM\_ADMIN Constants Used as Parameter Values**

| Constant              | Value | Type   | Description                                                              |
|-----------------------|-------|--------|--------------------------------------------------------------------------|
| ILM_EXECUTION_OFFLINE | 1     | NUMBER | Specifies that the object may be offline while ADO action is performed.  |
| ILM_EXECUTION_ONLINE  | 2     | NUMBER | Specifies that the object should be online while ADO action is performed |

**Table 90-2 (Cont.) DBMS\_ILM\_ADMIN Constants Used as Parameter Values**

| Constant           | Value | Type   | Description                                                         |
|--------------------|-------|--------|---------------------------------------------------------------------|
| ILM_ENABLED        | 1     | NUMBER | Indicates automatic ADO policy evaluation and execution is enabled  |
| ILM_DISABLED       | 2     | NUMBER | Indicates automatic ADO policy evaluation and execution is disabled |
| ILM_POLICY_IN_DAYS | 0     | NUMBER | Indicates policy is specified in days. This is the default.         |

Table 90-2 (Cont.) DBMS\_ILM\_ADMIN Constants Used as Parameter Values

| Constant              | Value | Type   | Description                                                                                                                                                 |
|-----------------------|-------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ILM_POLICY_IN_SECONDS | 1     | NUMBER | Indicates policy unit is changed from days to seconds. This could be used to test ADO policy evaluation quickly instead of waiting for the policy duration. |

Note:

- Setting ILM\_POLICY\_IN\_SECONDS does not compress the blocks within the specified seconds.
- Setting ILM\_POLICY\_IN\_SECONDS is for test ADO and should not be set in the production environment.

## 90.4 Summary of DBMS\_ILM\_ADMIN Subprograms

This table lists and briefly describes the DBMS\_ILM\_ADMIN package subprograms.

**Table 90-3 DBMS\_ILM\_ADMIN Package Subprograms**

| Subprogram                                     | Description                                                                                                                                    |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CLEAR_HEAT_MAP_ALL Procedure</a>   | Deletes all rows except the dummy row                                                                                                          |
| <a href="#">CLEAR_HEAT_MAP_TABLE Procedure</a> | Clears all or some statistics for the heat map table, deleting rows for a given table or segment which match a given pattern, or all such rows |
| <a href="#">CUSTOMIZE_ILM Procedure</a>        | Customizes environment for ILM execution by specifying the values for ILM execution related parameters                                         |
| <a href="#">DISABLE_ILM Procedure</a>          | Turns off all background ILM scheduling                                                                                                        |
| <a href="#">ENABLE_ILM Procedure</a>           | Turns on all background ILM scheduling                                                                                                         |
| <a href="#">SET_HEAT_MAP_ALL Procedure</a>     | Updates or inserts heat map rows for all tables                                                                                                |
| <a href="#">SET_HEAT_MAP_START Procedure</a>   | Sets the start date for collecting heat map data                                                                                               |
| <a href="#">SET_HEAT_MAP_TABLE Procedure</a>   | Updates or inserts a row for the specified table or segment                                                                                    |

## 90.4.1 CLEAR\_HEAT\_MAP\_ALL Procedure

This procedure deletes all rows in `HEAT_MAP_STAT$` except the dummy row.

### Syntax

```
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_ALL;
```

## 90.4.2 CLEAR\_HEAT\_MAP\_TABLE Procedure

This procedure clears all or some statistics for the heat map table, deleting rows for a given table or segment which match a given pattern, or all such rows.

### Syntax

```
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_TABLE (
  owner          IN VARCHAR2,
  tablename      IN VARCHAR2,
  partition      IN VARCHAR2 default '',
  access_date    IN DATE DEFAULT NULL,
  segment_access_summary IN NUMBER DEFAULT NULL);
```

### Parameters

**Table 90-4 CLEAR\_HEAT\_MAP\_TABLE Procedure Parameters**

| Parameter   | Description                                                      |
|-------------|------------------------------------------------------------------|
| owner       | Table owner                                                      |
| tablename   | Table name                                                       |
| partition   | Name of the subobject, defaults to NULL                          |
| access_date | Date for the entry in <code>HEAT_MAP_STAT\$</code> to be removed |

**Table 90-4 (Cont.) CLEAR\_HEAT\_MAP\_TABLE Procedure Parameters**

| Parameter              | Description                                                                               |
|------------------------|-------------------------------------------------------------------------------------------|
| segment_access_summary | Summary of segment access constants indicating access operations performed on the segment |

### 90.4.3 CUSTOMIZE\_ILM Procedure

This procedure customizes environment for ILM execution by specifying the values for ILM execution related parameters. These values take effect for the next background scheduling.

#### Syntax

```
DBMS_ILM_ADMIN.CUSTOMIZE_ILM (
    parameter      IN      NUMBER,
    value          IN      NUMBER);
```

#### Parameters

**Table 90-5 CUSTOMIZE\_ILM Procedure Parameters**

| Parameter | Description                                                      |
|-----------|------------------------------------------------------------------|
| parameter | One of the parameter constants defined in DBMS_ILM_ADMIN package |
| value     | Value of parameter                                               |

### 90.4.4 DISABLE\_ILM Procedure

This procedure turns off all background ILM scheduling.

#### Syntax

```
DBMS_ILM_ADMIN.DISABLE_ILM;
```

### 90.4.5 ENABLE\_ILM Procedure

This procedure turns on all background ILM scheduling.

#### Syntax

```
DBMS_ILM_ADMIN.ENABLE_ILM;
```

### 90.4.6 SET\_HEAT\_MAP\_ALL Procedure

This procedure sets an HTTP request header. The request header is sent to the Web server as soon as it is set.

#### Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_ALL (
    access_date      IN DATE,
    segment_access_summary IN NUMBER);
```

## Parameters

**Table 90-6** *SET\_HEAT\_MAP\_ALL Procedure Parameters*

| Parameter              | Description                                                                               |
|------------------------|-------------------------------------------------------------------------------------------|
| access_date            | Date for the entry in HEAT_MAP_STAT\$ to be added                                         |
| segment_access_summary | Summary of segment access constants indicating access operations performed on the segment |

## 90.4.7 SET\_HEAT\_MAP\_START Procedure

This procedure sets the start date for collecting heat map data.

### Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_START (
    start_date IN DATE);
```

## Parameters

**Table 90-7** *SET\_HEAT\_MAP\_START Procedure Parameters*

| Parameter  | Description                                                |
|------------|------------------------------------------------------------|
| start_date | Indicates the new date from which all statistics are valid |

## 90.4.8 SET\_HEAT\_MAP\_TABLE Procedure

This procedure updates or inserts a row for the specified table or segment.

### Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_TABLE (
    owner           IN VARCHAR2,
    tablename       IN VARCHAR2,
    partition       IN VARCHAR2 DEFAULT '',
    access_date     IN DATE DEFAULT NULL,
    segment_access_summary IN NUMBER DEFAULT NULL);
```

## Parameters

**Table 90-8** *SET\_HEAT\_MAP\_TABLE Procedure Parameters*

| Parameter              | Description                                                                               |
|------------------------|-------------------------------------------------------------------------------------------|
| owner                  | Table owner                                                                               |
| tablename              | Table name                                                                                |
| partition              | Name of the subobject, defaults to NULL                                                   |
| access_date            | Date for the entry in HEAT_MAP_STAT\$ to be added                                         |
| segment_access_summary | Summary of segment access constants indicating access operations performed on the segment |

# DBMS\_IMMUTABLE\_TABLE

Immutable tables are read-only tables that protect data against unauthorized modification. They also prevent against accidental data modifications that may be caused by human errors. The `DBMS_IMMUTABLE_TABLE` package allows you to delete the expired rows in an immutable table.

This chapter contains the following topics:

- [DBMS\\_IMMUTABLE\\_TABLE Overview](#)
- [DBMS\\_IMMUTABLE\\_TABLE Security Model](#)
- [Summary of DBMS\\_IMMUTABLE\\_TABLE Subprograms](#)

## See Also:

- *Oracle Database Administrator's Guide*
- *Oracle Database SQL Language Reference*
- *Oracle Database Reference*

## 91.1 DBMS\_IMMUTABLE\_TABLE Overview

Immutable tables are `read-only` tables that protect data against unauthorized modification. Immutable tables also prevent against accidental data modifications that may be caused by human errors. You must specify a retention period for the immutable table and for rows within the immutable table. An immutable table can be dropped if it contains no rows or if the specified retention period for the table has lapsed. Rows can be deleted from an immutable table only after the specified retention period for rows in the table has elapsed. Except for increasing the retention periods, you cannot modify the definition of an immutable table.

## 91.2 DBMS\_IMMUTABLE\_TABLE Security Model

The `DBMS_IMMUTABLE_TABLE` package is owned by `sys` and is installed as part of database installation. The routines in the package are run with invoker's rights and hence run with the privileges of the current user.

## 91.3 Summary of DBMS\_IMMUTABLE\_TABLE Subprograms

This table lists the `DBMS_IMMUTABLE_TABLE` subprograms in alphabetical order and briefly describes them.

Table 91-1 DBMS\_IMMUTABLE\_TABLE Package Subprograms

| Subprogram                                    | Description                              |
|-----------------------------------------------|------------------------------------------|
| <a href="#">DELETE_EXPIRED_ROWS Procedure</a> | This procedure deletes the expired rows. |

91.3.1 DELETE\_EXPIRED\_ROWS Procedure

This procedure deletes some or all of the expired rows from the immutable table. This procedure does not commit.

Syntax

```
DBMS_IMMUTABLE_TABLE.DELETE_EXPIRED_ROWS (
  schema_name          IN VARCHAR2,
  table_name            IN VARCHAR2,
  before_timestamp      IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
  number_of_rows_deleted OUT NUMBER);
```

Parameters

Table 91-2 DELETE\_EXPIRED\_ROWS Procedure Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name            | The name of the schema.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| table_name             | The name of the immutable table.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| before_timestamp       | If the parameter is NULL, all expired rows in the table are deleted. If the parameter is not NULL and older than the timestamp calculated based on current time and row retention time, rows with timestamps less than the parameter value are deleted. If the parameter is younger than the timestamp calculated based on the current time and row retention time, the calculated timestamp is used, and all expired rows are deleted.<br>The default value is NULL. |
| number_of_rows_deleted | The number of rows deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

# DBMS\_INMEMORY

The `DBMS_INMEMORY` package provides an interface for In-Memory Column Store (IM column store) functionality.

This chapter contains the following topics:

- [DBMS\\_INMEMORY Overview](#)
- [DBMS\\_INMEMORY Security Model](#)
- [Summary of DBMS\\_INMEMORY Subprograms](#)

## 92.1 DBMS\_INMEMORY Overview

This package contains procedures for populating and repopulating the IM column store, and for dropping IM expressions from a specified table.

### IM Population and Repopulation

In-Memory population (population) occurs when the database reads existing row-format data from disk, transforms it into columnar format, and then stores it in the IM column store. Only objects with the `INMEMORY` attribute are eligible for population.

Population, which transforms existing data on disk into columnar format, is different from repopulation, which loads new data into the IM column store. Repopulation occurs automatically after their columnar data undergo significant DML activity.

When an object has the `INMEMORY` attribute and a priority other than `NONE`, the database gradually populates the object in the IM column store according to an internal priority queue. Objects with priority of `NONE` are populated only when they undergo a full scan.

The `DBMS_INMEMORY.POPULATE` procedure forces immediate population of an object. The `DBMS_INMEMORY.REPOPULATE` procedure forces immediate repopulation of an object.

### IM Expressions

IM expressions populate frequently evaluated query expressions in the IM column store for subsequent reuse. An IM expression is materialized as a hidden virtual column, prefixed with the string `SYS_IME`, and is accessed in the same way as a non-virtual column.

When you use `DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS`, the database adds the 20 hottest expressions to their respective tables as `SYS_IME` columns and applies the default `INMEMORY` column compression clause. If any `SYS_IME` columns that were added during a previous invocation are no longer in the latest expression list, then the database changes their attribute to `NO INMEMORY`.

The maximum number of `SYS_IME` columns for a table, regardless of whether the attribute is `INMEMORY` or `NO INMEMORY`, is 50. After the 50 expression limit is reached for a table, the database will not add new `SYS_IME` columns. To make space for new expressions, you must manually drop `SYS_IME` columns with the `DBMS_INMEMORY.IME_DROP_EXPRESSIONS` or `DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS` procedures.

## 92.2 DBMS\_INMEMORY Security Model

The `DBMS_INMEMORY` package subprograms execute with invoker's rights.

The `POPULATE` and `REPOPULATE` procedures require the invoking user to have `SELECT` privileges on the specified object. For `IME_DROP_EXPRESSIONS`, the invoking user must have `ALTER TABLE` privileges on the specified table.

## 92.3 Summary of DBMS\_INMEMORY Subprograms

This table lists and briefly describes the `DBMS_INMEMORY` package subprograms.

**Table 92-1 DBMS\_INMEMORY Package Subprograms**

| Subprogram                                            | Description                                                                |
|-------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">IME_DROP_EXPRESSIONS Procedure</a>        | Drops a specified set of <code>SYS_IME</code> virtual columns from a table |
| <a href="#">POPULATE Procedure</a>                    | Forces population of the specified table                                   |
| <a href="#">REPOPULATE Procedure</a>                  | Forces repopulation of the specified table                                 |
| <a href="#">SEGMENT_DEALLOCATE_VERSIONS Procedure</a> | Deallocates non-current IMCUs in the IM column store                       |

### 92.3.1 IME\_DROP\_EXPRESSIONS Procedure

This procedure drops a specified set of `SYS_IME` virtual columns from a table.

**Syntax**

```
DBMS_INMEMORY.IME_DROP_EXPRESSIONS(  
    schema_name    IN    VARCHAR2,  
    table_name     IN    VARCHAR2,  
    column_name    IN    VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 92-2 IME\_DROP\_EXPRESSIONS Procedure Parameters**

| Parameter   | Description                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------|
| schema_name | The name of the schema that contains the In-Memory table                                                          |
| table_name  | The name of the In-Memory table that contains the SYS_IME columns                                                 |
| column_name | The name of the SYS_IME column. By default this value is null, which specifies all SYS_IME columns in this table. |

## Usage Notes

Typical reasons for dropping SYS\_IME columns are space and performance. The maximum number of SYS\_IME columns for a table, regardless of whether the attribute is INMEMORY or NO INMEMORY, is 50. After the 50-expression limit is reached for a table, the database will not add new SYS\_IME columns. To make space for new expressions, you must manually drop SYS\_IME columns with the DBMS\_INMEMORY.IME\_DROP\_EXPRESSIONS or DBMS\_INMEMORY\_ADMIN.IME\_DROP\_ALL\_EXPRESSIONS procedures.

To drop a specified SYS\_IME column or all SYS\_IME columns in the requested table, use DBMS\_INMEMORY.IME\_DROP\_EXPRESSIONS . To populate these segments again, either invoke the DBMS\_INMEMORY.POPULATE procedure, or perform a full table scan.

## 92.3.2 POPULATE Procedure

This procedure forces population of the specified table, partition, or subpartition into the IM column store.

## Syntax

```
DBMS_INMEMORY.POPULATE (  
    schema_name      IN    VARCHAR2,  
    table_name       IN    VARCHAR2,  
    subobject_name   IN    VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 92-3 POPULATE Procedure Parameters**

| Parameter      | Description               |
|----------------|---------------------------|
| schema_name    | Name of schema            |
| table_name     | Name of table             |
| subobject_name | Partition or subpartition |

### 92.3.3 REPOPULATE Procedure

This procedure forces repopulation of a table, partition, or subpartition that is currently populated in the IM column store.

#### Syntax

```
DBMS_INMEMORY.REPOPULATE(  
    schema_name      IN    VARCHAR2,  
    table_name       IN    VARCHAR2,  
    subobject_name   IN    VARCHAR2 DEFAULT NULL,  
    force            IN    BOOLEAN DEFAULT FALSE);
```

#### Parameters

**Table 92-4 REPOPULATE Procedure Parameters**

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name    | Name of the schema that owns the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| table_name     | Name of the table requiring repopulation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| subobject_name | Name of the partition or subpartition. If null, then repopulate the entire table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| force          | <p>Whether to repopulate all IMCUs in the segment, just as in initial population.</p> <p>The following values are possible for the <code>force</code> parameter:</p> <ul style="list-style-type: none"><li>• <code>FALSE</code> — The database repopulates only IMCUs containing modified rows. This is the default.</li><li>• <code>TRUE</code> — The database drops the segment, and then rebuilds it. The database increments the statistics and performs all other tasks related to initial population.</li></ul> <p>For example, IMCU 1 contains rows 1 to 500,000, and IMCU 2 contains rows 500,001 to 1,000,000. A statement modifies row 600,000. When <code>force</code> is <code>FALSE</code>, the database only repopulates IMCU 2. When <code>force</code> is <code>TRUE</code>, the database repopulates both IMCUs.</p> <p>Consider further that the <code>INMEMORY_VIRTUAL_COLUMNS</code> initialization parameter is set to <code>ENABLE</code>, and an application creates a new virtual column. When <code>force</code> is <code>FALSE</code>, the database only repopulates IMCU 2 with the new column. When <code>force</code> is <code>TRUE</code>, the database repopulates both IMCUs with the new column.</p> |

### 92.3.4 SEGMENT\_DEALLOCATE\_VERSIONS Procedure

This procedure deallocates non-current IMCUs in the IM column store.

#### Syntax

```
DBMS_INMEMORY.SEGMENT_DEALLOCATE_VERSIONS(  
    SCHEMA_NAME      IN    VARCHAR2,  
    TABLE_NAME      IN    VARCHAR2,  
    PARTITION_NAME   IN    VARCHAR2 DEFAULT NULL,  
    SPCPRESSURE      IN    BOOLEAN DEFAULT FALSE);
```

Parameters

Table 92-5 SEGMENT\_DEALLOCATE\_VERSIONS Procedure Parameters

| Parameter      | Description                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name    | Name of the schema that owns the object.                                                                                                                                                        |
| table_name     | Name of the table requiring repopulation.                                                                                                                                                       |
| partition_name | Name of the partition or subpartition. If null, then repopulate the entire table.                                                                                                               |
| spppressure    | Whether to force deallocation of non-current IMCUs (TRUE), or wait for the database to deallocate them automatically. By default, the database deallocates non-current IMCUs every two minutes. |

Usage Notes

During repopulation, the IM column store maintains both the current IMCU and non-current IMCU. This mechanism, which is called *double buffering*, ensures that queries do not decrease performance because an IMCU is unavailable during repopulation. After repopulation completes, the IM column store retains the non-current IMCU for a short time (2 minutes by default) to optimize queries with older SCNs. Typically, the default behavior is sufficient. However, you can force deallocation of non-current IMCUs by using the SEGMENT\_DEALLOCATE\_VERSIONS procedure.

Example

The following program forces deallocation of non-current IMCUs for the products table:

```
BEGIN
  DBMS_INMEMORY.SEGMENT_DEALLOCATE_VERSIONS (
    schema_name => 'SH'
  , table_name  => 'PRODUCTS'
  , spppressure => TRUE );
END;
```

# DBMS\_INMEMORY\_ADMIN

DBMS\_INMEMORY\_ADMIN provides interfaces for managing an In-Memory FastStart (IM FastStart) area and In-Memory Expressions (IM expressions).

This chapter contains the following topics:

- [DBMS\\_INMEMORY\\_ADMIN Overview](#)
- [DBMS\\_INMEMORY\\_ADMIN Security Model](#)
- [DBMS\\_INMEMORY\\_ADMIN Operational Notes](#)
- [Summary of DBMS\\_INMEMORY\\_ADMIN Subprograms](#)

## See Also:

*Oracle Database In-Memory Guide* to learn more about Oracle Database In-Memory features

## 93.1 DBMS\_INMEMORY\_ADMIN Overview

This package provides interfaces for managing In-Memory Expressions (IM expressions) and the In-Memory FastStart (IM FastStart) area.

### IM Expressions

Analytic queries often contain complex expressions or calculations that consume significant CPU and memory during execution. Use `IME_CAPTURE_EXPRESSIONS` to identify these frequently used (“hot”) expressions and `IME_POPULATE_EXPRESSIONS` to populate them in the IM column store. By using IM expressions, the database avoids repeated computations and improves performance.

The database represents IM expressions as system-generated virtual columns. The name of an IM virtual column begins with `SYS_IME`. You can also use

`DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS` and `DBMS_INMEMORY.IME_DROP_EXPRESSIONS` to remove existing `SYS_IME` columns.

The `DBA_IM_EXPRESSIONS` view shows the `SYS_IME` columns that have the `INMEMORY` attribute. After using the `IME_CAPTURE_EXPRESSIONS` procedure, you can query this view to see the hot expressions added to different tables in the database.

## See Also:

*Oracle Database In-Memory Guide* to learn more about IM expressions

## IM FastStart Area

The IM FastStart area stores data that optimizes the population of the IM column store when the database restarts. Because the database reads columnar data directly from persistent storage without needing to compress or format it, population is faster when a database instance restarts.

When you enable IM FastStart for the IM column store, you must specify an ASSM tablespace for the IM FastStart area. The tablespace stores the data in a SecureFiles LOB named `SYSDBIMFS_LOGSEG$`. The `SYSAUX` tablespace stores the metadata. When data is populated or repopulated in the IM column store, the database automatically writes the data to the IM FastStart area. You cannot manually force a write. If you specify an object as `NO INMEMORY`, then the database removes it from the IM FastStart area.

When the IM FastStart area is under space pressure, the database automatically drops the oldest 15% of segments and continues saving columnar data. If space is unavailable, then the database stops writing to the IM FastStart area.

### See Also:

*Oracle Database In-Memory Guide* to learn more about IM expressions

## Automatic In-Memory

Automatic In-Memory uses access tracking and column statistics to manage objects in the IM column store. If the IM column store is full, and if other more frequently accessed segments would benefit from population in the IM column store, then the IM column store evicts inactive segments. If the IM column store is configured to hold all `INMEMORY` segments, however, then Automatic In-Memory takes no action.

By default, Automatic In-Memory checks usage statistics for the past 31 days. You can change the current setting by supplying the `AIM_STATWINDOW_DAYS` parameter to `DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER`.

### See Also:

*Oracle Database In-Memory Guide* to learn more about Automatic In-Memory

## Database In-Memory Wait on Populate

The `POPULATE_WAIT` function initiates population of all `INMEMORY` objects that have a priority greater than or equal to the specified priority, and then returns a status value for the population. A user-specified interval specifies the maximum time that the function waits before returning the value to the caller.

*Oracle Database In-Memory Guide* to learn more about the wait on populate feature

## 93.2 DBMS\_INMEMORY\_ADMIN Security Model

This package requires administrator privileges. Package subprograms execute with invoker's rights.

## 93.3 DBMS\_INMEMORY\_ADMIN Operational Notes

It is possible for a DBMS\_INMEMORY\_ADMIN FastStart operation to fail or be interrupted.

In a failure or interruption scenario, the following rules determine which subprograms you can use:

- If FASTSTART\_ENABLE does not succeed, then the only permitted operation is re-executing FASTSTART\_ENABLE.
- If FASTSTART\_MIGRATE\_STORAGE does not succeed, then the only permitted operation is re-executing FASTSTART\_MIGRATE\_STORAGE.
- If FASTSTART\_DISABLE does not succeed, then all DBMS\_INMEMORY\_ADMIN operations are permitted.

## 93.4 Summary of DBMS\_INMEMORY\_ADMIN Subprograms

This table lists the DBMS\_INMEMORY\_ADMIN subprograms and briefly describes them.

**Table 93-1 DBMS\_INMEMORY\_ADMIN Package Subprograms**

| Subprogram                                          | Description                                                                                                                          |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">AIM_GET_PARAMETER Procedure</a>         | This procedure obtains the current values for parameters that control Automatic In-Memory.                                           |
| <a href="#">AIM_SET_PARAMETER Procedure</a>         | The procedure customizes the execution environment of Automatic In-Memory                                                            |
| <a href="#">FASTSTART_DISABLE Procedure</a>         | This procedure disables the In-Memory FastStart (IM FastStart) feature.                                                              |
| <a href="#">FASTSTART_ENABLE Procedure</a>          | This procedure enables IM FastStart and assigns a tablespace.                                                                        |
| <a href="#">FASTSTART_MIGRATE_STORAGE Procedure</a> | This procedure moves all IM FastStart data and metadata from the existing tablespace to the specified new tablespace.                |
| <a href="#">GET_FASTSTART_TABLESPACE Function</a>   | This function returns the name of the tablespace that is currently designated for IM FastStart.                                      |
| <a href="#">IME_CAPTURE_EXPRESSIONS Procedure</a>   | This procedure captures the 20 most frequently accessed ("hottest") expressions in the database in the specified time interval.      |
| <a href="#">IME_CLOSE_CAPTURE_WINDOW Procedure</a>  | This procedure signals the end of the current expression capture window.                                                             |
| <a href="#">IME_DROP_ALL_EXPRESSIONS Procedure</a>  | This procedure drops all SYS_IME expression virtual columns in the database.                                                         |
| <a href="#">IME_GET_CAPTURE_STATE Procedure</a>     | This procedure returns the current capture state of the expression capture window and the timestamp of the most recent modification. |

**Table 93-1 (Cont.) DBMS\_INMEMORY\_ADMIN Package Subprograms**

| Subprogram                                         | Description                                                                                                                                                                       |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">IME_OPEN_CAPTURE_WINDOW Procedure</a>  | This procedure signals the beginning of an expression capture window.                                                                                                             |
| <a href="#">IME_POPULATE_EXPRESSIONS Procedure</a> | This procedure forces the population of expressions captured in the latest invocation of <code>DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS</code> .                               |
| <a href="#">POPULATE_WAIT Function</a>             | Initiates population of all INMEMORY objects that have a priority greater than or equal to the specified priority, and sets a timeout interval within which population must occur |

### 93.4.1 AIM\_GET\_PARAMETER Procedure

This procedure obtains the current values for parameters that control Automatic In-Memory.

#### Syntax

```
DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(  
    parameter    IN    NUMBER,  
    value        OUT   NUMBER);
```

#### Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| parameter | Specifies a predefined constant that controls Automatic In-Memory.<br>The only valid constant is <code>AIM_STATWINDOW_DAYS</code> , which specifies the number of days in the sliding statistics window. Automatic In-Memory uses this duration to filter statistics for INMEMORY objects as part of its algorithms. For example, if the duration is set to 7 days, then Automatic In-Memory considers only statistics of the past 7 days for its algorithms. The default is 31. |
| value     | Specifies the value assigned to <code>AIM_STATWINDOW_DAYS</code> .                                                                                                                                                                                                                                                                                                                                                                                                               |

#### Example 93-1 Getting the Number of Days in the Statistics Window

The following code prints the number of days in the statistics window to the screen:

```
VARIABLE b_statwin NUMBER  
  
BEGIN  
  
    DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS,  
        :b_statwin);  
    END;  
    /  
  
    PRINT b_statwin
```

Sample output appears below:

```
B_STATWIN
-----
        14
```

**See Also:**

*Oracle Database In-Memory Guide* to learn how to use `AIM_GET_PARAMETER`

## 93.4.2 AIM\_SET\_PARAMETER Procedure

The procedure customizes the execution environment of Automatic In-Memory.

### Syntax

```
DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER (
    parameter    IN    NUMBER,
    value        IN    NUMBER);
```

### Parameters

| Parameter | Description                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| parameter | Specifies a predefined constant that controls Automatic In-Memory.<br>The only valid constant is <code>AIM_STATWINDOW_DAYS</code> , which specifies the number of days in the sliding statistics window. The default is 31. |
| value     | Assigns the value assigned to <code>AIM_STATWINDOW_DAYS</code> .                                                                                                                                                            |

### Example 93-2 Setting the Number of Days in the Statistics Window

The following example gets the current number of days in the window, sets it to 14, and then prints the value to the screen:

```
VARIABLE b_statwin NUMBER

BEGIN

DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS,
    :b_statwin);
END;
/

PRINT b_statwin

BEGIN

DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS,
    14);
END;
/
```

```
BEGIN

DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS,
:b_statwin);
END;
/

PRINT b_statwin
```

Sample output appears below:

```
B_STATWIN
-----
          31

B_STATWIN
-----
          14
```

#### See Also:

*Oracle Database In-Memory Guide* to learn how to use `AIM_GET_PARAMETER`

### 93.4.3 FASTSTART\_DISABLE Procedure

This procedure disables the In-Memory FastStart (IM FastStart) feature.

#### Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_DISABLE();
```

#### Security Model

Administrator privileges are required to execute this procedure.

#### Usage Notes

When you execute the procedure, the database executes the following actions:

1. Waits until all IM FastStart operations complete
2. Disables the IM FastStart feature, and performs the following operations:
  - Cleans the IM FastStart area
  - Deletes IM FastStart metadata stored in the `SYSAUX` tablespace
  - Releases the IM FastStart tablespace (but does not delete it)

This procedure does not interrupt or affect any concurrent IM column store operations.

## Examples

The following PL/SQL program disables the IM FastStart feature:

```
EXEC DBMS_INMEMORY_ADMIN.FASTSTART_DISABLE;
```

The following query shows that the LOB for the IM FastStart tablespace has been deleted (sample output included):

```
COL OWNER FORMAT a5
COL SEGMENT_NAME FORMAT a20
SELECT 1.OWNER, 1.SEGMENT_NAME, SUM(s.BYTES)/1024/1024 MB
FROM DBA_LOBS l, DBA_SEGMENTS s
WHERE 1.SEGMENT_NAME = s.SEGMENT_NAME
AND 1.TABLESPACE_NAME = 'FS_TBS'
GROUP BY 1.OWNER, 1.SEGMENT_NAME;

no rows selected
```

## 93.4.4 FASTSTART\_ENABLE Procedure

This procedure enables In-Memory FastStart (IM FastStart), and designates a tablespace for the IM FastStart (FastStart) area.

### Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_ENABLE (
    tbs_name      IN      VARCHAR2,
    nologging     IN      BOOLEAN DEFAULT TRUE);
```

### Parameters

**Table 93-2 FASTSTART\_ENABLE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tbs_name  | The name of the ASSM tablespace for the FastStart area.                                                                                                                                                                                                                                                                                  |
| nologging | The logging mode of the LOB created for the FastStart area.<br>If the <code>nologging</code> parameter is set to <code>FALSE</code> , then the database creates the FastStart LOB with the <code>LOGGING</code> option. If set to <code>TRUE</code> (default), then the database creates the LOB with the <code>NOLOGGING</code> option. |

### Security Model

Administrator privileges are required to execute this procedure.

### Usage Notes

To enable IM FastStart, the ASSM tablespace specified in `FASTSTART_ENABLE` must exist, and the `SYSAUX` tablespace must be online. Only one FastStart tablespace can exist for every PDB or non-CDB. The specified tablespace must have enough space to store data for the IM column store, and it must not contain any other data before it is designated for the FastStart

area. Oracle recommends sizing the tablespace at least twice of the size of the `INMEMORY_SIZE` initialization parameter.

The database does not create the FastStart area on disk until the IM column store is populated. After population, the data periodically saves the columnar data (but not metadata such as the transaction journal) to the FastStart area, which is represented on disk as the `SYSDBIMFS_LOBSEG$` segment. The database stores the FastStart metadata in the `SYSAUX` tablespace. In an Oracle Real Application Clusters (Oracle RAC) environment, IM FastStart data is shared across all nodes.

#### Note:

IM FastStart is not supported in a standby database instance.

Whereas the initial loading of IMCUs into memory is expensive and CPU-bound, an IM FastStart tablespace requires intermittent I/O. The database periodically writes columnar data to the IM FastStart area. If a database instance must restart, then Oracle Database reads the columnar data directly from the IM FastStart area rather than reconstructing the IMCUs from scratch. No compression or formatting of the columnar data is required.

### Examples

This example creates `fs_tbs` as an ASSM tablespace, and then uses `FASTSTART_ENABLE` to specify this tablespace as the IM FastStart area:

```
CREATE TABLESPACE fs_tbs
  DATAFILE 'fs_tbs.dbf' SIZE 500M
  EXTENT MANAGEMENT LOCAL
  SEGMENT SPACE MANAGEMENT AUTO;

EXEC DBMS_INMEMORY_ADMIN.FASTSTART_ENABLE('fs_tbs');
```

The following query shows that the IM FastStart LOB was created (sample output included):

```
COL OWNER FORMAT a5
COL SEGMENT_NAME FORMAT a20
SELECT  l.OWNER, l.SEGMENT_NAME, SUM(s.BYTES)/1024/1024 MB
FROM    DBA_LOBS l, DBA_SEGMENTS s
WHERE   l.SEGMENT_NAME = s.SEGMENT_NAME
AND     l.TABLESPACE_NAME = 'FS_TBS'
GROUP BY l.OWNER, l.SEGMENT_NAME;
```

| OWNER | SEGMENT_NAME       | MB   |
|-------|--------------------|------|
| SYS   | SYSDBIMFS_LOBSEG\$ | .125 |

## 93.4.5 FASTSTART\_MIGRATE\_STORAGE Procedure

This procedure moves the In-Memory FastStart (IM FastStart) data and catalogs from the current tablespace to a new tablespace.

### Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_MIGRATE_STORAGE (
    tbs_name    IN    VARCHAR2 );
```

### Parameters

**Table 93-3 FASTSTART\_MIGRATE\_STORAGE Procedure Parameters**

| Parameter | Description                                                    |
|-----------|----------------------------------------------------------------|
| tbs_name  | The name of the new ASSM tablespace for the IM FastStart area. |

### Security Model

DBA privileges are required to execute this procedure.

### Usage Notes

When you execute the procedure, the database executes the following actions:

1. Waits until all IM FastStart operations complete
2. Disables the IM FastStart feature
3. Copies IM FastStart data and metadata to the new tablespace, leaving the old tablespace intact
4. Re-enables IM FastStart the feature

### Examples

The following program obtains the name of the IM FastStart tablespace, if one exists, and prints the result (sample output included):

```
VARIABLE b_fstbs VARCHAR2(20)
BEGIN
    :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
-----
FS_TBS
```

The following statements create a new tablespace named fs\_tbs2, and then migrate the IM FastStart area to this tablespace:

```
CREATE TABLESPACE fs_tbs2
    DATAFILE 'fs_tbs2.dbf' SIZE 500M
```

```
EXTENT MANAGEMENT LOCAL
SEGMENT SPACE MANAGEMENT AUTO;

EXEC DBMS_INMEMORY_ADMIN.FASTSTART_MIGRATE_STORAGE('fs_tbs2');
```

The following program prints the name of the current IM FastStart tablespace (sample output included):

```
BEGIN
    :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
-----
FS_TBS2
```

## 93.4.6 GET\_FASTSTART\_TABLESPACE Function

This function returns the tablespace assigned to In-Memory FastStart (IM FastStart). If the feature is disabled, then the function returns NOT ENABLED.

### Syntax

```
DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE();
```

### Security Model

DBA privileges are required to execute this function.

### Examples

This program obtains the name of the IM FastStart tablespace, if one exists, and prints the result:

```
VARIABLE b_fstbs VARCHAR2(20)
BEGIN
    :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
-----
NOT ENABLED
```

## 93.4.7 IME\_CAPTURE\_EXPRESSIONS Procedure

This procedure captures the 20 most frequently accessed (“hottest”) expressions in the database in the specified time interval.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS (
    snapshot    IN    VARCHAR2);
```

### Parameters

**Table 93-4 IME\_CAPTURE\_EXPRESSIONS Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| snapshot  | <p>Specifies a snapshot that defines the time interval in which expression statistics are considered.</p> <p>You can specify any of the following values:</p> <ul style="list-style-type: none"> <li>• CUMULATIVE<br/>The database considers all expression statistics since the creation of the database.</li> <li>• CURRENT<br/>The database considers only expression statistics from the past 24 hours.</li> <li>• WINDOW<br/>The database considers statistics for expressions tracked in the most recent expression capture window.<br/>The database adds hidden virtual columns for expressions tracked in the most recent window. If the capture window is currently open, then the database considers all expressions tracked in the current window up until this point, and then materializes the hottest expressions. To list the expressions that have been tracked in the current window, query <code>DBA_EXPRESSION_STATISTICS</code> with <code>SNAPSHOT='WINDOW'</code>.</li> </ul> |

### Usage Notes

When you invoke this procedure, the database queries the Expression Statistics Store (ESS), and considers only expressions on tables that are at least partially populated in the IM column store. The database adds the 20 hottest expressions to their respective tables as hidden virtual columns, prefixed with the string `SYS_IME`, and applies the default `INMEMORY` column compression clause. If any `SYS_IME` columns added during a previous invocation are no longer in the latest top 20 list, then the database marks them as `NO INMEMORY`.

#### Note:

Executing the `IME_CAPTURE_EXPRESSIONS` procedure on a standby database has no effect.

The maximum number of `SYS_IME` columns for a table, regardless of whether the attribute is `INMEMORY` or `NO INMEMORY`, is 50. After the limit is reached for a table, the database will not add new `SYS_IME` columns. To make space for new expressions, you must manually drop `SYS_IME`

columns with the [IME\\_DROP\\_ALL\\_EXPRESSIONS Procedure](#) or [IME\\_DROP\\_EXPRESSIONS Procedure](#).

The 50-expression limit for each table, which includes both `INMEMORY` and `NO INMEMORY` expressions, is different from the 20-expression limit for the database, which includes only `INMEMORY` expressions. For example, if 20 tables are populated in the IM column store, then each table might each have 1 `SYS_IME` column with the `INMEMORY` attribute, and 49 `SYS_IME` columns with the `NO INMEMORY` attribute.

IM expressions and virtual columns are stored in In-Memory structured called In-Memory Expression Units (IMEUs). Every IMEU is linked to a parent In-Memory Compression Unit (IMCU) from which it inherits compression characteristics.

ESS information is stored in the data dictionary and exposed in the `DBA_EXPRESSION_STATISTICS` view. This view shows the metadata that the optimizer has collected in the ESS. IM expressions are exposed as system-generated virtual columns, prefixed by the string `SYS_IME`, in the `DBA_IM_EXPRESSIONS` view.

### Example 93-3 Capturing Expressions in a User-Defined Window

This example demonstrates use of the `WINDOW` capture mode. Your goal is to open and close an expression capture window, and then capture all expressions that the database tracked during this window. You perform the following steps:

1. Open an expression capture window, generate expressions, and then close the window:

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
-- Generate expressions for the database to track
EXEC DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
```

2. Query `DBA_EXPRESSION_STATISTICS` (sample output included):

```
COL OWNER FORMAT A6
COL TABLE_NAME FORMAT A9
COL COUNT FORMAT 99999
COL CREATED FORMAT A10
COL EXPRESSION_TEXT FORMAT A29

SELECT OWNER, TABLE_NAME, EVALUATION_COUNT AS COUNT,
       CREATED, EXPRESSION_TEXT
FROM   DBA_EXPRESSION_STATISTICS
WHERE  SNAPSHOT = 'WINDOW'
AND    OWNER = 'SH';
```

| OWNER | TABLE_NAME | COUNT | CREATED   | EXPRESSION_TEXT               |
|-------|------------|-------|-----------|-------------------------------|
| SH    | SALES      | 4702  | 09-OCT-17 | "QUANTITY_SOLD"               |
| SH    | SALES      | 4702  | 09-OCT-17 | "QUANTITY_SOLD"*"AMOUNT_SOLD" |
| SH    | SALES      | 4702  | 09-OCT-17 | "PROD_ID"                     |
| SH    | SALES      | 4702  | 09-OCT-17 | "CUST_ID"                     |
| SH    | SALES      | 4702  | 09-OCT-17 | "CHANNEL_ID"                  |
| SH    | SALES      | 4702  | 09-OCT-17 | "AMOUNT_SOLD"                 |

The preceding query shows both the columns tracked in the ESS and the expressions captured during the window for queries in the `sh` schema. During the most recent window, the database captured one expression: `QUANTITY_SOLD*AMOUNT_SOLD`.

3. Use `IME_CAPTURE_EXPRESSIONS` to make the database consider all expressions in the current window for materialization:

```
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('WINDOW');
```

4. Query `DBA_IM_EXPRESSIONS` (sample output included):

```
COL OWNER FORMAT a6
COL TABLE_NAME FORMAT a9
COL COLUMN_NAME FORMAT a25
SET LONG 50
SET LINESIZE 150

SELECT OWNER, TABLE_NAME, COLUMN_NAME, SQL_EXPRESSION
FROM   DBA_IM_EXPRESSIONS;
```

| OWNER | TABLE_NAME | COLUMN_NAME             | SQL_EXPRESSION                  |
|-------|------------|-------------------------|---------------------------------|
| SH    | SALES      | SYS_IME000100000025201B | "QUANTITY_SOLD" * "AMOUNT_SOLD" |

The preceding output shows all virtual columns that were added to the table and marked `INMEMORY` as part of the latest `IME_CAPTURE_EXPRESSIONS` invocation. The database gradually populates the captured expressions into the IM column store when it repopulates different IMCUs of the table.

5. Execute the following procedure to explicitly force a population of all captured IM expressions:

```
EXEC DBMS_INMEMORY_ADMIN.IME_POPULATE_EXPRESSIONS();
```

Note that you can populate IM expressions from a specific table by executing the `DBMS_INMEMORY.REPOPULATE` procedure with the `force` parameter set to `TRUE`.

#### Example 93-4 Capturing Expressions for the Past Day

The following program captures expressions tracked during the last 24 hours:

```
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('CURRENT');
```

## 93.4.8 IME\_CLOSE\_CAPTURE\_WINDOW Procedure

This procedure signals the end of the current expression capture window.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
```

### Usage Notes

On invocation of this procedure, the optimizer saves all gathered statistics to disk, and essentially freezes the expressions tracked in the window. The database preserves the statistics captured in this window until a new expression capture window is opened, at which point the database purges the statistics captured in the previous window.

### Example 93-5 Example

This example opens an expression capture window, and then issues `IME_CAPTURE_EXPRESSIONS('WINDOW')` so that the database considers all expressions in the current window for materialization. Finally, the example closes the window.

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
-- Generate expressions so that the database can track them
EXEC DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('WINDOW');
```

## 93.4.9 IME\_DROP\_ALL\_EXPRESSIONS Procedure

This procedure drops all `SYS_IME` expression virtual columns in the database.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS();
```

### Usage Notes

The `IME_DROP_ALL_EXPRESSIONS` procedure drops all `SYS_IME` columns from all tables, regardless of whether they have the `INMEMORY` attribute. In effect, the procedure acts as a database-wide reset button.

Using `IME_DROP_ALL_EXPRESSIONS` triggers a drop of all IMEUs *and* IMCUs for segments that have `SYS_IME` columns. For example, if 50 populated tables have one `SYS_IME` column each, then `IME_DROP_ALL_EXPRESSIONS` removes all 50 tables from the IM column store. To populate these segments again, you must use the `DBMS_INMEMORY.POPULATE` procedure or perform a full table scan.

## 93.4.10 IME\_GET\_CAPTURE\_STATE Procedure

This procedure returns the current capture state of the expression capture window and the timestamp of the most recent modification.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_GET_CAPTURE_STATE(
    p_capture_state OUT VARCHAR2,
    p_last_modified OUT TIMESTAMP);
```

### Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p_capture_state</code> | Describes the current state of the expression capture window.<br>The following states are possible: <ul style="list-style-type: none"> <li>OPEN — Indicates that the window is open.</li> <li>CLOSED — Indicates that the window is closed.</li> <li>DEFAULT — Indicates that the window has not been used. It is equivalent to the CLOSED state.</li> </ul> |
| <code>p_last_modified</code> | Indicates the timestamp of the most recent action.                                                                                                                                                                                                                                                                                                           |

## Usage Notes

This procedure is useful for avoiding conflicting calls for [IME\\_OPEN\\_CAPTURE\\_WINDOW Procedure](#) and [IME\\_CLOSE\\_CAPTURE\\_WINDOW Procedure](#). For example, if the current expression capture window state is `OPEN`, then you cannot open another window, and if the window state is `CLOSED`, then you cannot close a window.

### Example 93-6 Determining the State of an Expression Capture Window

This example opens an expression capture window, and then determines its capture state.

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();

VARIABLE b_state VARCHAR2(25)
VARIABLE b_time  VARCHAR2(10)
EXECUTE DBMS_INMEMORY_ADMIN.IME_GET_CAPTURE_STATE(:b_state, :b_time)
PRINT b_state b_time
```

The following sample output indicates that an expression capture window is currently open:

```
B_STATE
-----
OPEN

B_TIME
-----
09-OCT-17
```

## 93.4.11 IME\_OPEN\_CAPTURE\_WINDOW Procedure

This procedure signals the beginning of an expression capture window.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
```

### Security Model

Administrator privileges are required to execute this procedure.

## Usage Notes

On invocation of this procedure, the optimizer begins a new window snapshot and starts tracking expressions that occur within this window. An expression capture window is global across all instances in an Oracle RAC database.

Conflicting actions are not permitted. For example, in an Oracle RAC database, opening expression capture window on instance 1 at time t0 and attempting to open another expression capture window on instance 2 at time t1 before closing the first window is a conflicting action. To obtain the current capture state and reduce the potential for conflicting procedure invocations, use the [IME\\_GET\\_CAPTURE\\_STATE Procedure](#).

### Example

This following program opens an expression capture window:

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
```

## 93.4.12 IME\_POPULATE\_EXPRESSIONS Procedure

This procedure forces the population of expressions captured in the latest invocation of DBMS\_INMEMORY\_ADMIN.IME\_CAPTURE\_EXPRESSIONS.

### Syntax

```
DBMS_INMEMORY_ADMIN.IME_POPULATE_EXPRESSIONS();
```

### Usage Notes

If you do not invoke this procedure, then the database gradually repopulates SYS\_IME columns when their parent IMCUs are repopulated. If a table is not repopulated, then any new SYS\_IME columns captured by the IME\_CAPTURE\_EXPRESSIONS procedure are not populated. IME\_POPULATE\_EXPRESSIONS solves this problem by forcing population.

Internally, the procedure invokes DBMS\_INMEMORY.REPOPULATE for all tables that have SYS\_IME columns with the INMEMORY attribute. To populate SYS\_IME columns in a specified subset of tables, use DBMS\_INMEMORY.REPOPULATE instead of IME\_POPULATE\_EXPRESSIONS.

## 93.4.13 POPULATE\_WAIT Function

This function initiates population of all INMEMORY objects that have a priority greater than or equal to the specified priority, and returns a status value for the population. A user-specified interval specifies the maximum time that the function waits before returning the value to the caller.

### Syntax

```
DBMS_INMEMORY_ADMIN.POPULATE_WAIT(
    priority    IN    VARCHAR2 DEFAULT 'LOW',
    percentage  IN    NUMBER   DEFAULT 100,
    timeout     IN    NUMBER   DEFAULT 99999999,
    force       IN    BOOLEAN  DEFAULT FALSE)
RETURN VARCHAR2;
```

### Parameters

**Table 93-5 POPULATE\_WAIT Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| priority  | Specifies that the database populate all INMEMORY objects with the specified priority setting or higher. The default priority is LOW.<br><br>NONE is considered lowest priority. If you set to priority to NONE, then this function waits for all INMEMORY objects to populate. |

**Table 93-5 (Cont.) POPULATE\_WAIT Function Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| percentage | Specifies the percentage of population required for the function to consider population to be complete. The default is 100.<br><br>For example, if <code>percentage</code> is 50 and <code>priority</code> is <code>NONE</code> , and if 50% of the <code>INMEMORY</code> objects are populated in the IM column store, then the function returns the value 0 (population successful).                                                                                                                                                                                                                                        |
| timeout    | Specifies the number of seconds that must pass before the function returns -1, which indicates that the populate operation timed out. The default is 99999999 seconds, which is 115.74 days.<br><br>Assume that <code>timeout</code> is 600, <code>priority</code> is <code>LOW</code> , and <code>percentage</code> is 100. If 10 minutes pass, but all <code>PRIORITY LOW</code> objects are not yet fully populated, then the function returns -1.                                                                                                                                                                         |
| force      | Specifies that the database should drop all <code>INMEMORY</code> segments that have a priority greater than or equal than the specified priority, and then repopulate these segments. The default is <code>FALSE</code> .<br><br>Assume that the <code>INMEMORY</code> attribute applies to the <code>sales</code> table, which is partitioned. Only half the <code>sales</code> partitions are currently populated in the IM column store. If you execute <code>POPULATE_WAIT</code> with <code>force</code> set to <code>TRUE</code> , then the database drops all <code>sales</code> segments, and then repopulates them. |

#### Return Values

The following table describes the possible return values for `POPULATE_WAIT`. The function returns the values 0, 1, 2, and 3 only if the condition is met before the end of the interval specified by `timeout`. For example, if `timeout` is 600, then the function returns 1 only if an out-of-memory error occurs before 600 seconds pass. The function returns -1 only if the end of the timeout interval occurs *before* the database completes the requested operation.

**Table 93-6 Return Values for POPULATE\_WAIT**

| Constant                                  | Value | Description                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>POPULATE_TIMEOUT</code>             | -1    | The function timed out while waiting for population to complete.<br><br>Existing population jobs continue running in the background after -1 is returned. Reissuing <code>POPULATE_TIMEOUT</code> after -1 is returned reinitiates population; segments that are already populated are not dropped. |
| <code>POPULATE_SUCCESS</code>             | 0     | All objects that met the <code>priority</code> criteria were populated to the specified percentage of completion.                                                                                                                                                                                   |
| <code>POPULATE_OUT_OF_MEMORY</code>       | 1     | The In-Memory pool had insufficient memory to populate the objects that met the <code>priority</code> criteria to the specified percentage of completion.                                                                                                                                           |
| <code>POPULATE_NO_INMEMORY_OBJECTS</code> | 2     | No <code>INMEMORY</code> objects met the specified <code>priority</code> criteria.                                                                                                                                                                                                                  |

**Table 93-6 (Cont.) Return Values for POPULATE\_WAIT**

| Constant                    | Value | Description                                |
|-----------------------------|-------|--------------------------------------------|
| POPULATE_INMEMORY_SIZE_ZERO | 3     | The In-Memory column store is not enabled. |

### Usage Notes

Sample use cases for ensuring that objects are populated include:

- When the database is closed, open the database with `STARTUP RESTRICT` so that only administrators can access the database, and then execute `POPULATE_WAIT` with the desired timeout setting. If `POPULATE_WAIT` returns -1, indicating a timeout, then reexecute `POPULATE_WAIT`. When the function returns 0, disable the restricted session so that non-administrative users can query the database.
- Block database connections by using services or an application tier technique. When no analytic indexes exists, and when the application depends on the IM column store to provide reasonable performance, these techniques prevent runaway queries.

### Example 93-7 Specifying a Timeout Interval for In-Memory Population

In this example, the database contains a number of In-Memory tables with a variety of priority settings. Your goal is to populate every In-Memory table to 100% completion in a restricted database session, and then disable the restricted session so that the application can be guaranteed of querying only the In-Memory representations.

Assume that the database is shut down. In SQL\*Plus, you connect to an idle instance as SYSDBA, and then execute the following command (sample output included):

```
SQL> STARTUP RESTRICT
ORACLE instance started.

Total System Global Area 1157624280 bytes
Fixed Size                8839640 bytes
Variable Size             754974720 bytes
Database Buffers         16777216 bytes
Redo Buffers              7933952 bytes
In-Memory Area            369098752 bytes
Database mounted.
Database opened.
```

The database is open, but is accessible only to administrative users. You execute the following statements in SQL\*Plus (sample output shown in bold):

```
VARIABLE b_pop_status NUMBER

SELECT DBMS_INMEMORY_ADMIN.POPULATE_WAIT (
    priority    => 'NONE' ,
    percentage  => 100    ,
    timeout     => 300    )
    INTO b_pop_status
FROM   DUAL;
```

```
PRINT b_pop_status  
-1
```

After 5 minutes, the function returns the number -1. This code indicates that the function timed out while waiting for population to complete. 5 minutes is not long enough to populate all INMEMORY tables. You re-execute the SELECT statement, specifying a 30-minute timeout:

```
SELECT DBMS_INMEMORY_ADMIN.POPULATE_WAIT(  
    priority => 'NONE' ,  
    percentage => 100 ,  
    timeout => 1800 )  
    INTO b_pop_status  
FROM    DUAL;  
  
PRINT b_pop_status  
0
```

After 8 minutes, the function returns the number 0. This code indicates that all tables are completely populated. You now disable the restricted session so that the application can start query In-Memory objects with full confidence that only In-Memory representations will be accessed:

```
ALTER SYSTEM DISABLE RESTRICTED SESSION;
```

## DBMS\_INMEMORY\_ADVISE

This package enables you to determine if a workload can benefit from Oracle's Database In-Memory feature.

### 94.1 DBMS\_INMEMORY\_ADVISE Overview

DBMS\_INMEMORY\_ADVISE provides tools to determine the benefit of the Database In-Memory feature to the workflow on a database.

DBMS\_INMEMORY\_ADVISE perform its analysis on the workload of the current database. You can do the same analysis on another database workload by importing and examining AWR snapshots.

### 94.2 Summary of DBMS\_INMEMORY\_ADVISE Subprograms

In Oracle Database 19c, DBMS\_INMEMORY\_ADVISE includes a single subprogram: IS\_INMEMORY\_ELIGIBLE.

**Table 94-1 DBMS\_INMEMORY\_ADVISE Subprograms**

| Subprogram                                     | Description                                                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">IS_INMEMORY_ELIGIBLE Procedure</a> | Examines AWR snapshots to determine if a given workload will benefit or not benefit from the Database In-Memory feature. |

### 94.3 IS\_INMEMORY\_ELIGIBLE Procedure

This procedure examines Automatic Workload Repository (AWR) snapshots from a database to determine the workload's eligibility for Database In-Memory technology.

Many workloads benefit from Database In-Memory, however some may not.

IS\_INMEMORY\_ELIGIBLE determines whether or not a workload would benefit from Database In-Memory and should be considered eligible or ineligible. Eligibility is gauged by the percentage of analytical activity in the workload. If you are planning to implement Database In-Memory, you can use this tool to quickly identify and filter out databases that are ineligible; those where analytic activity is low and where you would see no substantive gain from the use of Database In-Memory. You can then focus your Database In-Memory deployment on databases whose workload includes more analytic activity and could therefore benefit substantially.

#### Criterion Used by IS\_INMEMORY\_ELIGIBLE

The determination that a workflow is eligible or ineligible for Database In-Memory is based on a system-defined threshold. If the percentage of the workload involved analytic activity is below that threshold, then Database In-Memory will not noticeably improve performance. The greater the level of activity above that target analytic workload percentage threshold, the greater is the potential benefit that may be seen from use of Database In-Memory.

## IS\_INMEMORY\_ELIGIBLE Procedure Syntax

IS\_INMEMORY\_ELIGIBLE has three overloads that let you choose how to define the scope of the eligibility test. The output parameters are the same in all three. The optional input parameter SNAP\_DBID is also common.

The input parameters are mutually exclusive to each overload as shown in the syntax below. You cannot combine them in a single procedure call.

### Syntax 1: Input as Most Recent *n* Days, Including Today

```
DBMS_INMEMORY_ADVISE.IS_INMEMORY_ELIGIBLE (
    TIME_WINDOW_DAYS    IN NUMBER,
    INMEM_ELIGIBLE       OUT BOOLEAN,
    ANALYSIS_SUMMARY     OUT VARCHAR2,
    SNAP_DBID            IN NUMBER DEFAULT NULL
);
```

### Syntax 2: Input as a Snapshot Range

```
DBMS_INMEMORY_ADVISE.IS_INMEMORY_ELIGIBLE (
    START_SNAP_ID        IN NUMBER,
    END_SNAP_ID           IN NUMBER,
    INMEM_ELIGIBLE        OUT BOOLEAN,
    ANALYSIS_SUMMARY      OUT VARCHAR2,
    SNAP_DBID             IN NUMBER DEFAULT NULL
);
```

### Syntax 3: Input as Time Interval (Start Time and End Time)

```
DBMS_INMEMORY_ADVISE.IS_INMEMORY_ELIGIBLE (
    START_TIME            IN TIMESTAMP,
    END_TIME              IN TIMESTAMP,
    INMEM_ELIGIBLE        OUT BOOLEAN,
    ANALYSIS_SUMMARY      OUT VARCHAR2,
    SNAP_DBID             IN NUMBER DEFAULT NULL
);
```

## Parameters

**Table 94-2 IS\_INMEMORY\_ELIGIBLE Procedure Parameters**

| Parameter        | Description                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| TIME_WINDOW_DAYS | All snapshots occurring within the last <i>n</i> number of days, including today.                                                                  |
| START_TIME       | Specifies the start of a timespan for snapshot analysis. All AWR snapshots created after START_TIME, up to and included END_TIME are examined.     |
| END_TIME         | Specifies the end of a timespan for snapshot analysis. All AWR snapshots created prior to END_TIME, back to and including START_TIME are examined. |

**Table 94-2 (Cont.) IS\_INMEMORY\_ELIGIBLE Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| START_SNAP_ID    | The first snapshot in a sequence of snapshots. This is the starting point of the workload to be analyzed.                                                                                                                                                          |
| END_SNAP_ID      | The end of a sequence of snapshots.                                                                                                                                                                                                                                |
| INMEM_ELIGIBLE   | The determination of whether or not the workflow is eligible for (will benefit from) Database In-Memory. Possible values: True, False.                                                                                                                             |
| ANALYSIS_SUMMARY | The analysis that explains the INMEM_ELIGIBLE evaluation. Example: Observed Analytic Workload Percentage is 3% is less than target Analytic Workload Percentage 20% Workloads with a percentage of analytical activity less than target are considered ineligible. |
| SNAP_DBID        | Database ID of a database from where AWR data has been exported. This enables you to analyze the workload on another database. If you are testing for eligibility on the current database, exclude this parameter.                                                 |

### Usage Notes

Within a given workload, the level of analytical activity may vary over a series of snapshots. Depending on which subset of all available snapshots are selected for testing, the analytic workload percentage calculated by `IS_INMEMORY_ELIGIBLE` may correspondingly vary. So you may want to do several evaluations with different input parameters. Using the `TIME_WINDOW_DAYS` parameter gives you a quick summary of the workload based on that time window. Then you can drill down into specific time periods, using the parameters based on snapshot IDs to get a perspective on patterns in the workload.

If you are considering whether or not to enable Database In-Memory on your databases, do the following:

1. Run the In-Memory Eligibility Test on candidate databases to find out which databases can or cannot effectively use Database In-Memory.
2. Run the In-Memory Advisor on any Oracle 19c database, except those that the In-Memory Eligibility Test has determined are ineligible.

### Examples

**Example 1:** Testing for eligibility within the time window of the last *n* days as input.

```
set serverout on;
set lines 200;

DECLARE
    inmem_eligible BOOLEAN;
    analysis_summary VARCHAR2(200);
BEGIN

    dbms_inmemory_advise.is_inmemory_eligible(1, inmem_eligible,
analysis_summary);
```

```

        DBMS_OUTPUT.PUT_LINE(
            CASE WHEN inmem_eligible = TRUE
                THEN 'Eligibile for In Memory'
                ELSE 'Not Eligible for In Memory'
            END
        );

        DBMS_OUTPUT.PUT_LINE(analysis_summary);

END;
/

```

**Example 2:** Testing for eligibility with a range of snapshot IDs as input.

```

set serverout on;
set lines 200;
DECLARE
    inmem_eligible BOOLEAN;
    analysis_summary VARCHAR2(200);
BEGIN

    dbms_inmemory_advise.is_inmemory_eligible(355, 356, inmem_eligible,
analysis_summary);

    DBMS_OUTPUT.PUT_LINE(
        CASE WHEN inmem_eligible = TRUE
            THEN 'Eligibile for In Memory'
            ELSE 'Not Eligible for In Memory'
        END
    );

    DBMS_OUTPUT.PUT_LINE(analysis_summary);

END;
/

```

**Example 3:** Testing for eligibility with a time interval as input. All snapshots beginning and ending within the time interval are included.

```

set serverout on;
set lines 200;
DECLARE
    inmem_eligible BOOLEAN;
    analysis_summary VARCHAR2(120);
BEGIN

    dbms_inmemory_advise.is_inmemory_eligible(TO_TIMESTAMP('21-JUN-23
05.22.27.262 PM', 'DD-Mon-RR HH:MI:SS.FF AM'),
                                                    TO_TIMESTAMP('21-JUN-23
05.26.04.446 PM', 'DD-Mon-RR HH:MI:SS.FF AM'),
inmem_eligible,
analysis_summary
    );

```

```
DBMS_OUTPUT.PUT_LINE(  
    CASE WHEN inmem_eligible = TRUE  
        THEN 'Eligibile for In Memory'  
        ELSE 'Not Eligible for In Memory'  
    END  
);  
  
DBMS_OUTPUT.PUT_LINE(analysis_summary);  
  
END;  
/
```

# DBMS\_IOT

The `DBMS_IOT` package creates a table into which references to the chained rows for an index-organized table can be placed using the `ANALYZE` command. `DBMS_IOT` can also create an exception table into which references to the rows of an index-organized table that violate a constraint can be placed during the `enable_constraint` operation.

`DBMS_IOT` is not loaded during database installation. To install `DBMS_IOT`, run `dbmsiotc.sql`, available in the `ADMIN` directory.

This chapter contains the following topics:

- [Summary of DBMS\\_IOT Subprograms](#)

**Note:**

With the introduction of logical-rowids for IOTs with Oracle Database Release 8.1, you no longer need to use the procedures contained in this package which is retained for backward compatibility only. It is however required for servers running with Oracle Database Release 8.0.

## 95.1 Summary of DBMS\_IOT Subprograms

This table lists and briefly describes the `DBMS_IOT` subprograms.

**Table 95-1** *DBMS\_IOT Package Subprograms*

| Subprogram                                       | Description                                                                                                                                 |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">BUILD_CHAIN_ROWS_TABLE Procedure</a> | Creates a table into which references to the chained rows for an index-organized table can be placed using the <code>ANALYZE</code> command |
| <a href="#">BUILD_EXCEPTIONS_TABLE Procedure</a> | Creates an exception table into which rows of an index-organized table that violate a constraint can be placed                              |

### 95.1.1 BUILD\_CHAIN\_ROWS\_TABLE Procedure

This procedure creates a table into which references to the chained rows for an index-organized table can be placed using the `ANALYZE` command.

**Syntax**

```
DBMS_IOT.BUILD_CHAIN_ROWS_TABLE (  
  owner          IN VARCHAR2,  
  iot_name       IN VARCHAR2,  
  chainrow_table_name IN VARCHAR2 default 'IOT_CHAINED_ROWS');
```

## Parameters

**Table 95-2 BUILD\_CHAIN\_ROWS\_TABLE Procedure Parameters**

| Parameter           | Description                               |
|---------------------|-------------------------------------------|
| owner               | Owner of the index-organized table.       |
| iot_name            | Index-organized table name.               |
| chainrow_table_name | Intended name for the chained-rows table. |

## Usage Notes

You should create a separate chained-rows table for each index-organized table to accommodate its primary key.

## Examples

```
CREATE TABLE l(a char(16),b char(16), c char(16), d char(240),
PRIMARY KEY(a,b,c)) ORGANIZATION INDEX pctthreshold 10 overflow;
EXECUTE DBMS_IOT.BUILD_CHAIN_ROWS_TABLE('SYS','L','LC');
```

A chained-row table is created with the following columns:

| Column Name       | Null? | Type          |
|-------------------|-------|---------------|
| OWNER_NAME        |       | VARCHAR2 (30) |
| TABLE_NAME        |       | VARCHAR2 (30) |
| CLUSTER_NAME      |       | VARCHAR2 (30) |
| PARTITION_NAME    |       | VARCHAR2 (30) |
| SUBPARTITION_NAME |       | VARCHAR2 (30) |
| HEAD_ROWID        |       | ROWID         |
| TIMESTAMP         |       | DATE          |
| A                 |       | CHAR (16)     |
| B                 |       | CHAR (16)     |
| C                 |       | CHAR (16)     |

## 95.1.2 BUILD\_EXCEPTIONS\_TABLE Procedure

This procedure creates an exception table.

Rows of an index-organized table that violate a constraint can be placed into this table during the execution of the following SQL statements:

- ALTER TABLE ... ENABLE CONSTRAINT ... EXCEPTIONS INTO
- ALTER TABLE ... ADD CONSTRAINT ... EXCEPTIONS INTO

## Syntax

```
DBMS_IOT.BUILD_EXCEPTIONS_TABLE (
  owner          IN VARCHAR2,
  iot_name       IN VARCHAR2,
  exceptions_table_name IN VARCHAR2 default 'IOT_EXCEPTIONS');
```

## Parameters

**Table 95-3 BUILD\_EXCEPTIONS\_TABLE Procedure Parameters**

| Parameter             | Description                         |
|-----------------------|-------------------------------------|
| owner                 | Owner of the index-organized table. |
| iot_name              | Index-organized table name.         |
| exceptions_table_name | Intended name for exception-table.  |

## Usage Notes

You should create a separate exception table for each index-organized table to accommodate its primary key.

## Examples

```
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE('SYS','L','LE');
```

An exception table for the preceding index-organized table with the following columns:

| Column Name | Null? | Type          |
|-------------|-------|---------------|
| -----       | ----- | ----          |
| ROW_ID      |       | VARCHAR2 (30) |
| OWNER       |       | VARCHAR2 (30) |
| TABLE_NAME  |       | VARCHAR2 (30) |
| CONSTRAINT  |       | VARCHAR2 (30) |
| A           |       | CHAR (16)     |
| B           |       | CHAR (16)     |
| C           |       | CHAR (16)     |

## DBMS\_JAVA

The DBMS\_JAVA package provides a PL/SQL interface for accessing database functionality from Java.

For a complete description of this package within the context of DBMS\_JAVA, see DBMS\_JAVA in the *Oracle Database Java Developer's Guide*

The `DBMS_JOB` package schedules and manages jobs in the job queue.

**Note:**

The `DBMS_JOB` package has been superseded by the `DBMS_SCHEDULER` package, and support for `DBMS_JOB` might be removed in future releases of Oracle Database. In particular, if you are administering jobs to manage system load, you are encouraged to disable `DBMS_JOB` by revoking the package execution privilege for users.

For more information, see [DBMS\\_SCHEDULER](#) and "Moving from `DBMS_JOB` to `DBMS_SCHEDULER`" in the *Oracle Database Administrator's Guide*.

This chapter contains the following topics:

- [Security Model](#)
- [Operational Notes](#)
- [Summary of DBMS\\_JOB Subprograms](#)

## 97.1 DBMS\_JOB Security Model

`DBMS_JOB` uses the same security policies as `DBMS_SCHEDULER`. You must have the `CREATE JOB` privilege to use `DBMS_JOB`.

Jobs cannot be altered or deleted other than jobs owned by the user. This is true for all users including those users granted DBA privileges.

You can execute procedures that are owned by the user for which the user is explicitly granted `EXECUTE`. However, procedures for which the user is granted the execute privilege through roles cannot be executed.

Note that, once a job is started and running, there is no easy way to stop the job.

## 97.2 DBMS\_JOB Operational Notes

These notes describe stopping a job, and working with Oracle Real Application Clusters.

### Stopping a Job

Note that, once a job is started and running, there is no easy way to stop the job.

### Working with Oracle Real Application Clusters

`DBMS_JOB` supports multi-instance execution of jobs. By default jobs can be executed on any instance, but only one single instance will execute the job. In addition, you can force instance binding by binding the job to a particular instance. You implement instance binding by

specifying an instance number to the instance affinity parameter. Note, however, that in Oracle Database 10g Release 1 (10.1) instance binding is not recommended. Service affinity is preferred. This concept is implemented in the [DBMS\\_SCHEDULER](#) package.

The following procedures can be used to create, alter or run jobs with instance affinity. Note that not specifying affinity means any instance can run the job.

- `DBMS_JOB.SUBMIT`
- `DBMS_JOB.INSTANCE`
- `DBMS_JOB.CHANGE`
- `DBMS_JOB.RUN`

### DBMS\_JOB.SUBMIT

To submit a job to the job queue, use the following syntax:

```
DBMS_JOB.SUBMIT(  
  job      OUT    BINARY_INTEGER,  
  what     IN     VARCHAR2,  
  next_date IN     DATE DEFAULT SYSDATE,  
  interval IN     VARCHAR2 DEFAULT 'NULL',  
  no_parse IN     BOOLEAN DEFAULT FALSE,  
  instance IN     BINARY_INTEGER DEFAULT ANY_INSTANCE,  
  force    IN     BOOLEAN DEFAULT FALSE);
```

Use the parameters `instance` and `force` to control job and instance affinity. The default value of `instance` is 0 (zero) to indicate that any instance can execute the job. To run the job on a certain instance, specify the `instance` value. Oracle displays error ORA-23319 if the `instance` value is a negative number or `NULL`.

The `force` parameter defaults to `false`. If `force` is `TRUE`, any positive integer is acceptable as the job instance. If `force` is `FALSE`, the specified instance must be running, or Oracle displays error number ORA-23428.

### DBMS\_JOB.INSTANCE

To assign a particular instance to execute a job, use the following syntax:

```
DBMS_JOB.INSTANCE(  
  job      IN BINARY_INTEGER,  
  instance IN BINARY_INTEGER,  
  force    IN BOOLEAN DEFAULT FALSE);
```

The `FORCE` parameter in this example defaults to `FALSE`. If the `instance` value is 0 (zero), job affinity is altered and any available instance can execute the job despite the value of `force`. If the `INSTANCE` value is positive and the `FORCE` parameter is `FALSE`, job affinity is altered only if the specified instance is running, or Oracle displays error ORA-23428.

If the `force` parameter is `TRUE`, any positive integer is acceptable as the job instance and the job affinity is altered. Oracle displays error ORA-23319 if the `instance` value is negative or `NULL`.

### DBMS\_JOB.CHANGE

To alter user-definable parameters associated with a job, use the following syntax:

```
DBMS_JOB.CHANGE(  
  job      IN BINARY_INTEGER,  
  what     IN VARCHAR2 DEFAULT NULL,  
  next_date IN DATE DEFAULT NULL,  
  interval IN VARCHAR2 DEFAULT NULL,
```

```
instance          IN BINARY_INTEGER DEFAULT NULL,  
force             IN BOOLEAN DEFAULT FALSE );
```

Two parameters, `instance` and `force`, appear in this example. The default value of `instance` is `null` indicating that job affinity will not change.

The default value of `force` is `FALSE`. Oracle displays error ORA-23428 if the specified instance is not running and error ORA-23319 if the `instance` number is negative.

### DBMS\_JOB.RUN

The `force` parameter for `DBMS_JOB.RUN` defaults to `FALSE`. If `force` is `TRUE`, instance affinity is irrelevant for running jobs in the foreground process. If `force` is `FALSE`, the job can run in the foreground only in the specified instance. Oracle displays error ORA-23428 if `force` is `FALSE` and the connected instance is the incorrect instance.

```
DBMS_JOB.RUN(  
  job      IN BINARY_INTEGER,  
  force    IN BOOLEAN DEFAULT FALSE);
```

## 97.3 Summary of DBMS\_JOB Subprograms

This table lists the `DBMS_JOB` subprograms and briefly describes them.

**Table 97-1 DBMS\_JOB Package Subprograms**

| Subprogram                             | Description                                                                                    |
|----------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">BROKEN Procedure</a>       | Disables job execution                                                                         |
| <a href="#">CHANGE Procedure</a>       | Alters any of the user-definable parameters associated with a job                              |
| <a href="#">INSTANCE Procedure</a>     | Assigns a job to be run by a instance                                                          |
| <a href="#">INTERVAL Procedure</a>     | Alters the interval between executions for a specified job                                     |
| <a href="#">NEXT_DATE Procedure</a>    | Alters the next execution time for a specified job                                             |
| <a href="#">REMOVE Procedure</a>       | Removes specified job from the job queue                                                       |
| <a href="#">RUN Procedure</a>          | Forces a specified job to run                                                                  |
| <a href="#">SUBMIT Procedure</a>       | Submits a new job to the job queue                                                             |
| <a href="#">USER_EXPORT Procedures</a> | Re-creates a given job for export, or re-creates a given job for export with instance affinity |
| <a href="#">WHAT Procedure</a>         | Alters the job description for a specified job                                                 |

### 97.3.1 BROKEN Procedure

This procedure sets the broken flag. Broken jobs are never run.

#### Syntax

```
DBMS_JOB.BROKEN (  
  job      IN BINARY_INTEGER,  
  broken   IN BOOLEAN,  
  next_date IN DATE DEFAULT SYSDATE);
```

## Parameters

**Table 97-2 BROKEN Procedure Parameters**

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |
| broken    | Sets the job as broken or not broken. TRUE sets it as broken; FALSE sets it as not broken.                        |
| next_date | Next date when the job will be run.                                                                               |

### Note:

If you set job as broken while it is running, Oracle resets the job's status to normal after the job completes. Therefore, only execute this procedure for jobs that are not running.

## Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- If a job fails 16 times in a row, Oracle automatically sets it as broken and then stops trying to run it.

## 97.3.2 CHANGE Procedure

This procedure changes any of the fields a user can set in a job.

### Syntax

```
DBMS_JOB.CHANGE (  
  job      IN  BINARY_INTEGER,  
  what     IN  VARCHAR2,  
  next_date IN  DATE,  
  interval IN  VARCHAR2,  
  instance IN  BINARY_INTEGER DEFAULT NULL,  
  force    IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 97-3 CHANGE Procedure Parameters**

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |
| what      | PL/SQL procedure to run.                                                                                          |
| next_date | Next date when the job will be run.                                                                               |
| interval  | Date function; evaluated immediately before the job starts running.                                               |

**Table 97-3 (Cont.) CHANGE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| instance  | When a job is submitted, specifies which instance can run the job. This defaults to <code>NULL</code> , which indicates that instance affinity is not changed.                                                                                                         |
| force     | <p>If this is <code>FALSE</code>, then the specified instance (to which the instance number change) must be running. Otherwise, the routine raises an exception.</p> <p>If this is <code>TRUE</code>, then any positive integer is acceptable as the job instance.</p> |

#### Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- The parameters `instance` and `force` are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.
- If the parameters `what`, `next_date`, or `interval` are `NULL`, then leave that value as it is.

#### Example

```
BEGIN
  DBMS_JOB.CHANGE(14144, null, null, 'sysdate+3');
COMMIT;
END;
```

## 97.3.3 INSTANCE Procedure

This procedure changes job instance affinity.

#### Syntax

```
DBMS_JOB.INSTANCE (
  job          IN BINARY_INTEGER,
  instance     IN BINARY_INTEGER,
  force        IN BOOLEAN DEFAULT FALSE);
```

#### Parameters

**Table 97-4 INSTANCE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the <code>JOB</code> column of the <code>USER_JOBS</code> or <code>DBA_JOBS</code> view.                                                                         |
| instance  | When a job is submitted, a user can specify which instance can run the job.                                                                                                                                                      |
| force     | If this is <code>TRUE</code> , then any positive integer is acceptable as the job instance. If this is <code>FALSE</code> (the default), then the specified instance must be running; otherwise the routine raises an exception. |

**Usage Notes**

Your job will not be available for processing by the job queue in the background until it is committed.

97.3.4 INTERVAL Procedure

This procedure changes how often a job runs.

**Syntax**

```
DBMS_JOB.INTERVAL (
  job          IN  BINARY_INTEGER,
  interval     IN  VARCHAR2);
```

**Parameters**

**Table 97-5** INTERVAL Procedure Parameters

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |
| interval  | Date function, evaluated immediately before the job starts running.                                               |

**Usage Notes**

- If the job completes successfully, then this new date is placed in next\_date. interval is evaluated by plugging it into the statement select interval into next\_date from dual;
- The interval parameter must evaluate to a time in the future. Legal intervals include:

| Interval                       | Description             |
|--------------------------------|-------------------------|
| 'sysdate + 7'                  | Run once a week.        |
| 'next_day(sysdate, 'TUESDAY')' | Run once every Tuesday. |
| 'null'                         | Run only once.          |

- If interval evaluates to NULL and if a job completes successfully, then the job is automatically deleted from the queue.
- Your job will not be available for processing by the job queue in the background until it is committed.

97.3.5 NEXT\_DATE Procedure

This procedure changes when an existing job next runs.

**Syntax**

```
DBMS_JOB.NEXT_DATE (
  job          IN  BINARY_INTEGER,
  next_date    IN  DATE);
```

## Parameters

**Table 97-6 NEXT\_DATE Procedure Parameters**

| Parameter | Description                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.                     |
| next_date | Date of the next refresh: it is when the job will be automatically run, assuming there are background processes attempting to run it. |

## Usage Notes

Your job will not be available for processing by the job queue in the background until it is committed.

## 97.3.6 REMOVE Procedure

This procedure removes an existing job from the job queue. This currently does not stop a running job.

### Syntax

```
DBMS_JOB.REMOVE (
    job          IN BINARY_INTEGER );
```

## Parameters

**Table 97-7 REMOVE Procedure Parameters**

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |

## Usage Notes

Your job will not be available for processing by the job queue in the background until it is committed.

### Example

```
BEGIN
    DBMS_JOB.REMOVE (14144);
    COMMIT;
END;
```

## 97.3.7 RUN Procedure

This procedure runs job JOB now. It runs it even if it is broken.

Running the job recomputes next\_date. See data dictionary view USER\_JOBS or DBA\_JOBS.

## Syntax

```
DBMS_JOB.RUN (
  job      IN  BINARY_INTEGER,
  force     IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 97-8 RUN Procedure Parameters**

| Parameter | Description                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.                                                                             |
| force     | If this is TRUE, then instance affinity is irrelevant for running jobs in the foreground process. If this is FALSE, then the job can be run in the foreground only in the specified instance. |

## Example

```
EXECUTE DBMS_JOB.RUN(14144);
```

### **WARNING:**

This re-initializes the current session's packages.

## Exceptions

An exception is raised if `force` is FALSE, and if the connected instance is the wrong one.

## 97.3.8 SUBMIT Procedure

This procedure submits a new job. It chooses the job from the sequence `sys.jobseq`.

## Syntax

```
DBMS_JOB.SUBMIT (
  job      OUT BINARY_INTEGER,
  what     IN  VARCHAR2,
  next_date IN  DATE DEFAULT SYSDATE,
  interval IN  VARCHAR2 DEFAULT 'null',
  no_parse IN  BOOLEAN DEFAULT FALSE,
  instance IN  BINARY_INTEGER DEFAULT any_instance,
  force     IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 97-9 SUBMIT Procedure Parameters**

| Parameter | Description                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view |

**Table 97-9 (Cont.) SUBMIT Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| what      | <p>PL/SQL text of the job to be run. This must be a valid PL/SQL statement or block of code. For example, to run a stored procedure <code>P</code>, you could pass the string <code>P</code>; (with the semi-colon) to this routine. The SQL that you submit in the <code>what</code> parameter is wrapped in the following PL/SQL block:</p> <pre> DECLARE   job BINARY_INTEGER := :job;   next_date DATE := :mydate;   broken BOOLEAN := FALSE; BEGIN   WHAT   :mydate := next_date;   IF broken THEN :b := 1; ELSE :b := 0; END IF; END;</pre> <p>Ensure that you include the <code>;</code> semi-colon with the statement.</p> |
| next_date | Next date when the job will be run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| interval  | Date function that calculates the next time to run the job. The default is <code>NULL</code> . This must evaluate to either a future point in time or <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| no_parse  | <p>A flag. The default is <code>FALSE</code>. If this is set to <code>FALSE</code>, then Oracle parses the procedure associated with the job. If this is set to <code>TRUE</code>, then Oracle parses the procedure associated with the job the first time that the job is run.</p> <p>For example, if you want to submit a job before you have created the tables associated with the job, then set this to <code>TRUE</code>.</p>                                                                                                                                                                                                |
| instance  | When a job is submitted, specifies which instance can run the job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| force     | If this is <code>TRUE</code> , then any positive integer is acceptable as the job instance. If this is <code>FALSE</code> (the default), then the specified instance must be running; otherwise the routine raises an exception.                                                                                                                                                                                                                                                                                                                                                                                                   |

**Usage Notes**

- Your job will not be available for processing by the job queue in the background until it is committed.
- The parameters `instance` and `force` are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.

**Example**

This submits a new job to the job queue. The job calls the procedure `DBMS_DDL.ANALYZE_OBJECT` to generate optimizer statistics for the table `DQUON.ACCOUNTS`. The statistics are based on a sample of half the rows of the `ACCOUNTS` table. The job is run every 24 hours:

```

VARIABLE jobno number;
BEGIN
  DBMS_JOB.SUBMIT(:jobno,
    'dbms_ddl.analyze_object(''TABLE'',
      ''DQUON'', ''ACCOUNTS'',
      ''ESTIMATE'', NULL, 50);'
    SYSDATE, 'SYSDATE + 1');
```

```
        COMMIT;
END;
/
Statement processed.
print jobno
JOBNO
-----
14144
```

### 97.3.9 USER\_EXPORT Procedures

There are two overloaded procedures. The first produces the text of a call to re-create the given job. The second alters instance affinity (8i and after) and preserves the compatibility.

#### Syntax

```
DBMS_JOB.USER_EXPORT (
  job      IN      BINARY_INTEGER,
  mycall   IN OUT  VARCHAR2);

DBMS_JOB.USER_EXPORT (
  job      IN      BINARY_INTEGER,
  mycall   IN OUT  VARCHAR2,
  myinst   IN OUT  VARCHAR2);
```

#### Parameters

**Table 97-10** USER\_EXPORT Procedure Parameter

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |
| mycall    | Text of a call to re-create the given job.                                                                        |
| myinst    | Text of a call to alter instance affinity.                                                                        |

### 97.3.10 WHAT Procedure

This procedure changes what an existing job does, and replaces its environment.

#### Syntax

```
DBMS_JOB.WHAT (
  job      IN  BINARY_INTEGER,
  what     IN  VARCHAR2);
```

#### Parameters

**Table 97-11** WHAT Procedure Parameters

| Parameter | Description                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| job       | System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view. |
| what      | PL/SQL procedure to run.                                                                                          |

### Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- Some legal values of `what` (assuming the routines exist) are:
  - `'myproc(''10-JAN-82'', next_date, broken);'`
  - `'scott.emppackage.give_raise(''JENKINS'', 30000.00);'`
  - `'dbms_job.remove(job);'`

# DBMS\_JSON

The `DBMS_JSON` package provides an interface for data-guide operations.

This chapter contains the following topics:

- [DBMS\\_JSON Overview](#)
- [DBMS\\_JSON Security Model](#)
- [DBMS\\_JSON Constants](#)
- [Summary of DBMS\\_JSON Subprograms](#)

## 98.1 DBMS\_JSON Overview

Package `DBMS_JSON` provides subprograms for manipulating JavaScript Object Notation (JSON) data that is stored in Oracle Database.

## 98.2 DBMS\_JSON Security Model

`PUBLIC` is granted the `EXECUTE` privilege on package `DBMS_JSON`. Its subprograms execute with invoker's rights privileges.

## 98.3 DBMS\_JSON Constants

The `DBMS_JSON` package uses these constants to define the JSON schema types, data-guide formatting options, and materialized view options. `DBMS_JSON` Constants for `mvrefreshmode` parameters are available only for Autonomous Database starting 19c.

**Table 98-1 DBMS\_JSON Constants Defined for JSON Data-Guide Formatting**

| Name                             | Value | Description                                        |
|----------------------------------|-------|----------------------------------------------------|
| <code>FORMAT_FLAT</code>         | 2     | Display flat format                                |
| <code>FORMAT_HIERARCHICAL</code> | 1     | Display hierarchical format                        |
| <code>PRETTY</code>              | 1     | Use appropriate indentation to improve readability |

**Table 98-2 DBMS\_JSON Constants for JSON Schema Types**

| Name                      | Type                   | Value | Description         |
|---------------------------|------------------------|-------|---------------------|
| <code>TYPE_ARRAY</code>   | <code>NUMBER(2)</code> | 6     | A JSON array        |
| <code>TYPE_BOOLEAN</code> | <code>NUMBER(2)</code> | 2     | A JSON boolean      |
| <code>TYPE_OBJECT</code>  | <code>NUMBER(2)</code> | 5     | A JSON object       |
| <code>TYPE_NULL</code>    | <code>NUMBER(2)</code> | 1     | The JSON NULL value |
| <code>TYPE_NUMBER</code>  | <code>NUMBER(2)</code> | 3     | A JSON number       |
| <code>TYPE_STRING</code>  | <code>NUMBER(2)</code> | 4     | A JSON string       |

**Table 98-3 DBMS\_JSON Constants for mvrefreshmode Parameter**

| Name                    | Type      | Value | Description                                              |
|-------------------------|-----------|-------|----------------------------------------------------------|
| MV_REFRESH_ON_STATEMENT | NUMBER(2) | 1     | Creates the materialized view with refresh on statement. |
| MV_REFRESH_ON_COMMIT    | NUMBER(2) | 2     | Creates the materialized view with refresh on commit.    |
| MV_REFRESH_ON_DEMAND    | NUMBER(2) | 3     | Creates the materialized view with refresh on demand.    |

## 98.4 Summary of DBMS\_JSON Subprograms

This table lists the DBMS\_JSON subprograms and briefly describes them.

### DBMS\_JSON Package Subprograms

| Subprogram                                     | Description                                                                                                                                                                                                                                                |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_VIRTUAL_COLUMNS Procedure</a>  | Add virtual columns based on data-guide information.<br><br>This has no effect when running on the shard catalog server — no virtual column is added.                                                                                                      |
| <a href="#">CREATE_VIEW Procedure</a>          | Create a view with relational columns and scalar JSON fields as specified in a data guide.                                                                                                                                                                 |
| <a href="#">CREATE_VIEW_ON_PATH Procedure</a>  | Create a view based on data-guide information, with relational columns, top-level scalar types, and fully expanded sub-tree under a given path.<br><br>When running on the shard catalog server this raises an error stating that the data guide is empty. |
| <a href="#">DROP_VIRTUAL_COLUMNS Procedure</a> | Drop virtual columns created by procedure <code>add_virtual_columns</code> .<br><br>This has no effect when running on the shard catalog server.                                                                                                           |
| <a href="#">GET_INDEX_DATAGUIDE Function</a>   | Get JSON data guide from a data guide-enabled JSON search index.<br><br>When running on the shard catalog server this returns a single empty row as result.                                                                                                |
| <a href="#">RENAME_COLUMN Procedure</a>        | Set the preferred name for a view column or a virtual column creating using a data guide.<br><br>This has no effect when running on the shard catalog server.                                                                                              |

 **Note:**

In the context of sharding, each individual shard maintains its own data-guide information, which is obtained from the JSON documents stored in that shard. When running on individual shard, procedures in this package that use data-guide information use only the information that is maintained for that shard.

## 98.4.1 ADD\_VIRTUAL\_COLUMNS Procedure

This procedure adds virtual columns based on the data guide.

The virtual column name is the value of `o:preferred_vc_name` in the data guide. The procedure ignores JSON objects, arrays, and fields under arrays in the data guide. Before it adds virtual columns, procedure `add_virtual_columns` first drops any existing virtual columns that were projected from fields in the same JSON column by a previous invocation of `add_virtual_columns` or by data-guide change-trigger procedure `add_vc` (in effect, it does what procedure `DBMS_JSON.drop_virtual_columns` does).

 **See Also:**

- [DROP\\_VIRTUAL\\_COLUMNS Procedure](#)
- *Oracle Database JSON Developer's Guide*

### Syntax

```
DBMS_JSON.ADD_VIRTUAL_COLUMNS (
    tablename           IN   VARCHAR2,
    jcolname            IN   VARCHAR2,
    dataguide           IN   CLOB,
    resolvableconflicts IN   BOOLEAN DEFAULT FALSE,
    colnameprefix       IN   VARCHAR2 DEFAULT NULL,
    mixedcasecolumns    IN   BOOLEAN  DEFAULT FALSE);
```

For the following signature you must have a data guide-enabled search index on the JSON column. This is not needed for the previous signature.

 **Note:**

The parameters `resolvableconflicts`, `colnameprefix`, and `mixedcasecolumns` are available only for Autonomous Database starting 19c.

```
DBMS_JSON.ADD_VIRTUAL_COLUMNS (
    tablename IN   VARCHAR2,
    jcolname  IN   VARCHAR2,
    frequency NUMBER DEFAULT 0,
    hidden    BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 98-4 ADD\_VIRTUAL\_COLUMNS Procedure Parameters**

| Parameter                                                                                                                                                                                      | Description                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tablename                                                                                                                                                                                      | Name of the table containing JSON column jcolname.                                                                                                                                                                                                                 |
| jcolname                                                                                                                                                                                       | Name of the JSON column in table tablename that contains the data from which to create the virtual column.                                                                                                                                                         |
| dataguide                                                                                                                                                                                      | The data guide. When o:hidden in the data guide for a particular JSON field is set to TRUE, the corresponding virtual column is added as a hidden column. The default value of o:hidden is FALSE.                                                                  |
| resolvenameconflicts                                                                                                                                                                           | By default, if there are any conflicts among o:preferred_column_name, an error is raised. By setting this parameter to TRUE, the procedure automatically resolves the virtual column name conflicts by appending a sequence number.<br>The default value is FALSE. |
| <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c release.</div>   |                                                                                                                                                                                                                                                                    |
| colnameprefix                                                                                                                                                                                  | By default, the virtual column name is the same as the JSON field name. This parameter allows you to add a prefix to the virtual column names.                                                                                                                     |
| <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c release.</div> |                                                                                                                                                                                                                                                                    |
| mixedcasenames                                                                                                                                                                                 | By default, the virtual column names are case sensitive. If this parameter value is set to TRUE, the virtual column names become non-case-sensitive.                                                                                                               |
| <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c release.</div> |                                                                                                                                                                                                                                                                    |
| frequency                                                                                                                                                                                      | Sets the minimum frequency threshold to display JSON columns. A frequency of 0 means display all JSON columns. Also, all JSON columns are displayed if statistics have not been collected, effectively overriding any value set by this parameter.                 |
| hidden                                                                                                                                                                                         | TRUE means the added virtual column is hidden; FALSE means it is not. The default is FALSE.                                                                                                                                                                        |

## Usage Notes

Procedure `DBMS_STATS.GATHER_STATS` collects statistics in the data guide. If the frequency statistic has not been collected, frequency is `NULL`. Setting the frequency to a value greater than zero means do not include columns for which there are no frequency statistics collected

(statistic is NULL), unless `DBMS_STATS.GATHER_STATS` has never been executed. In that case, the frequency parameter is ignored and all columns are displayed in the view.

## 98.4.2 CREATE\_VIEW Procedure

This procedure creates a view with relational columns, using scalar JSON fields as specified in the data guide. A data guide-enabled JSON search index is not required for this procedure; the data guide is passed to the procedure.

### See Also:

*Oracle Database JSON Developer's Guide*

### Syntax

```
PROCEDURE CREATE_VIEW (  
    viewname          VARCHAR2,  
    tablename         VARCHAR2,  
    jcolname          VARCHAR2,  
    dataguide         CLOB,  
    resourcepath      VARCHAR2 DEFAULT NULL,  
    materialize        BOOLEAN  DEFAULT FALSE,  
    mvrefreshmode     NUMBER    DEFAULT MV_REFRESH_ON_STATEMENT,  
    path              VARCHAR2 DEFAULT '$',  
    resolveconflicts  BOOLEAN  DEFAULT FALSE,  
    colnameprefix     VARCHAR2 DEFAULT NULL,  
    mixedcasecolumns  BOOLEAN  DEFAULT FALSE);
```

### Parameters

**Table 98-5 DBMS\_JSON.CREATE\_VIEW Procedure Parameters**

| Parameter    | Description                                                                 |
|--------------|-----------------------------------------------------------------------------|
| viewname     | Name of the view.                                                           |
| tablename    | Name of the table containing JSON column jcolname.                          |
| jcolname     | Name of the JSON column in table tablename that is used to create the view. |
| dataguide    | The data guide.                                                             |
| resourcepath | This parameter is for internal use. Value of this parameter is always NULL. |

### Note:

This parameter is available only for Autonomous Database starting 19c.

**Table 98-5 (Cont.) DBMS\_JSON.CREATE\_VIEW Procedure Parameters**

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>materialize</code>          | The value of this parameter is boolean and indicates if the view is materialized or not. <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div>                                                                                                                                                                                                                                                                                                                    |
| <code>mvrefreshmode</code>        | When <code>materialize</code> is true, this parameter specifies the materialized view refresh mode. <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div>                                                                                                                                                                                                                                                                                                         |
| <code>path</code>                 | For more information on materialized view refresh mode options, see <a href="#">DBMS_JSON Constants</a> .<br>The path of the JSON field to be expanded. It uses JSON path-expression syntax. It expands the descendants under the specified path, and creates view columns for each scalar value in the resulting sub-tree. The path <code>\$</code> creates a view starting from the JSON document root. <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div> |
| <code>resolvenameconflicts</code> | By default, if there are any conflicts among <code>o:preferred_column_name</code> , an error is raised. By setting this parameter to <code>TRUE</code> , the procedure automatically resolves the virtual column name conflicts by appending a sequence number. The default value is <code>FALSE</code> . <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div>                                                                                                 |

**Table 98-5 (Cont.) DBMS\_JSON.CREATE\_VIEW Procedure Parameters**

| Parameter                                                                                                                                                                            | Description                                                                                                                                               |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| colnameprefix                                                                                                                                                                        | By default, the view column name is the same as the JSON field name. This parameter allows users to provide a prefix to prepend to the view column names. |
| <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div> |                                                                                                                                                           |
| mixedcasecolumns                                                                                                                                                                     | By default, the view column names are case sensitive. You can use this parameter to change the case sensitivity behavior of the view column names.        |
| <div> <b>Note:</b><br/>This parameter is available only for Autonomous Database starting 19c.</div> |                                                                                                                                                           |

### 98.4.3 CREATE\_VIEW\_ON\_PATH Procedure

This procedure creates a view with relational columns, using top-level scalar values and the scalar values in the expanded sub-tree under a given path. The JSON column must have a data guide-enabled search index.

 **See Also:**  
*Oracle Database JSON Developer's Guide*

#### Syntax

```
PROCEDURE CREATE_VIEW_ON_PATH(  
    viewname VARCHAR2,  
    tablename VARCHAR2,  
    jcolname VARCHAR2,  
    path VARCHAR2,  
    frequency NUMBER DEFAULT 0);
```

#### Parameters

**Table 98-6 CREATE\_VIEW\_ON\_PATH Procedure Parameters**

| Parameter | Description       |
|-----------|-------------------|
| viewname  | Name of the view. |

**Table 98-6 (Cont.) CREATE\_VIEW\_ON\_PATH Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tablename | Name of the table containing JSON column jcolname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| jcolname  | Name of the JSON column in table <code>tablename</code> that is used to create the view. The column must have a data guide-enabled JSON search index, or else an error is raised.                                                                                                                                                                                                                                                                                                                                     |
| path      | The path of the JSON field to be expanded. It uses JSON path-expression syntax. It expands the descendants under the specified path, and creates view columns for each scalar value in the resulting sub-tree. The path <code>\$</code> creates a view starting from the JSON document root.                                                                                                                                                                                                                          |
| frequency | The minimum frequency threshold for displaying the JSON columns. A frequency of 0 means display all JSON columns. All JSON columns are also displayed if statistics have not been collected, effectively overriding any value set by this parameter. The view only displays JSON fields with frequency greater than the given <code>frequency</code> . It does not display JSON fields added after collecting statistics if the given frequency is greater than 0, if their statistic columns are <code>NULL</code> . |

## 98.4.4 DROP\_VIRTUAL\_COLUMNS Procedure

Drop all virtual columns that were added using PL/SQL procedure

`DBMS_JSON.add_virtual_columns` or using data-guide change-trigger procedure `add_vc`.

### See Also:

- [ADD\\_VIRTUAL\\_COLUMNS Procedure](#)
- *Oracle Database JSON Developer's Guide*

### Syntax

```
PROCEDURE DROP_VIRTUAL_COLUMNS (  
    tablename VARCHAR2,  
    jcolname VARCHAR2);
```

### Parameters

**Table 98-7 DBMS\_JSON.DROP\_VIRTUAL\_COLUMNS Procedure Parameters**

| Parameter | Description                                               |
|-----------|-----------------------------------------------------------|
| tablename | Name of the table containing JSON column jcolname.        |
| jcolname  | Name of the JSON column in table <code>tablename</code> . |

# 98.4.5 GET\_INDEX\_DATAGUIDE Function

GET\_INDEX\_DATAGUIDE gets JSON data guide from data guide-enabled JSON search index.

**See Also:**

*Oracle Database JSON Developer's Guide*

**Syntax**

```
FUNCTION GET_INDEX_DATAGUIDE(  
    tablename VARCHAR2,  
    jcolname VARCHAR2,  
    format NUMBER,  
    pretty NUMBER DEFAULT 0)  
RETURN CLOB;
```

**Parameters**

**Table 98-8 DBMS\_JSON.GET\_INDEX\_DATAGUIDE Procedure Parameters**

| Parameter | Description                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| tablename | Name of the table containing JSON column jcolname.                                                                                                     |
| jcolname  | Name of the JSON column in table tablename that has a data guide-enabled JSON search index.                                                            |
| format    | The data-guide format: <ul style="list-style-type: none"><li>• FORMAT_HIERARCHICAL — hierarchical format</li><li>• FORMAT_FLAT — flat format</li></ul> |
| pretty    | A value of DBMS_JSON.PRETTY means pretty-print the data guide, using indention to improve readability.                                                 |

**Example 98-1 Example Get Data Guide in Hierarchical Pretty Format**

This example returns the data guide in hierarchical format.

```
SELECT DBMS_JSON.GET_INDEX_DATAGUIDE('T1', 'PO',  
DBMS_JSON.FORMAT_HIERARCHICAL, DBMS_JSON.PRETTY)  
FROM DUAL;
```

# 98.4.6 RENAME\_COLUMN Procedure

This procedure sets the preferred name for a JSON column, to be used by the create view, or add virtual columns procedure.

**See Also:**

*Oracle Database JSON Developer's Guide*

**Syntax**

```
PROCEDURE RENAME_COLUMN(  
    tablename VARCHAR2,  
    jcolname VARCHAR2,  
    path VARCHAR2,  
    type NUMBER,  
    preferred_name VARCHAR2);
```

**Parameters**

**Table 98-9 RENAME\_COLUMN Procedure Parameters**

| Parameter      | Description                                                                                                                                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tablename      | Name of the table containing JSON column jcolname.                                                                                                                                                                                                                                                             |
| jcolname       | Name of the JSON column in table tablename. It must have a data guide-enabled JSON search index, or else an error is raised.                                                                                                                                                                                   |
| path           | Path to the JSON field on which to set the preferred column name.                                                                                                                                                                                                                                              |
| type           | The type of the JSON field targeted by path. Two JSON fields can have the same path if they are of different types. Possible values: <ul style="list-style-type: none"><li>• TYPE_NULL</li><li>• TYPE_STRING</li><li>• TYPE_NUMBER</li><li>• TYPE_BOOLEAN</li><li>• TYPE_OBJECT</li><li>• TYPE_ARRAY</li></ul> |
| preferred_name | Preferred name for the JSON field specified by path. If there is a name conflict, a system generated name is used instead.                                                                                                                                                                                     |

**Example 98-2 Example Renaming a Column**

This example renames a field to item\_name.

```
EXEC DBMS_JSON.RENAME_COLUMN('T1', 'PO', '$.purchaseOrder.items.name',  
DBMS_JSON.TYPE_STRING, 'item_name');
```

## DBMS\_LDAP

The DBMS\_LDAP package lets you access data from LDAP servers.

For a complete description of this package within the context of Oracle Internet Directory, see `DBMS_LDAP` in the *Application Developer's Guide for Oracle Identity Management*.

## DBMS\_LDAP\_UTL

The DBMS\_LDAP\_UTL package contains the Oracle Extension utility functions.

For a complete description of this package within the context of Oracle Internet Directory, see `DBMS_LDAP_UTL` in the *Application Developer's Guide for Oracle Identity Management*

# DBMS\_LIBCACHE

The `DBMS_LIBCACHE` package consists of one subprogram that prepares the library cache on an Oracle instance by extracting SQL and PL/SQL from a remote instance and compiling this SQL locally without execution. The value of compiling the cache of an instance is to prepare the information the application requires to execute in advance of failover or switchover.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Summary of DBMS\\_LIBCACHE Subprograms](#)

## 101.1 DBMS\_LIBCACHE Overview

Compiling a shared cursor consists of open, parse, and bind operations, plus the type-checking and execution plan functions performed at the first execution. All of these steps are executed in advance by the package `DBMS_LIBCACHE` for `SELECT` statements.

The open and parse functions are executed in advance for PL/SQL and DML. For PL/SQL, executing the parse phase has the effect of loading all library cache heaps other than the `MCODE`.

## 101.2 DBMS\_LIBCACHE Security Model

To execute `DBMS_LIBCACHE` you must directly access the same objects as do SQL statements. You can best accomplish this by utilizing the same user id as the original system on the remote system.

When there are multiple schema users, `DBMS_LIBCACHE` should be called for each.

Alternatively, `DBMS_LIBCACHE` may be called with the generic user `PARSER`. However, this user cannot parse the SQL that uses objects with access granted through roles. This is a standard PL/SQL security limitation.

## 101.3 Summary of DBMS\_LIBCACHE Subprograms

The `DBMS_LIBCACHE` package includes the `COMPILE_FROM_REMOTE` procedure subprogram.

**Table 101-1** *DBMS\_LIBCACHE Package Subprograms*

| Subprogram                                    | Description                                                                                |
|-----------------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">COMPILE_FROM_REMOTE Procedure</a> | Extracts SQL in batch from the source instance and compiles the SQL at the target instance |

## 101.3.1 COMPILE\_FROM\_REMOTE Procedure

This procedure extracts SQL in batch from the source instance and compiles the SQL at the target instance.

### Syntax

```
DBMS_LIBCACHE.COMPILE_FROM_REMOTE (
    p_db_link          IN      dbms_libcache$def.db_link$type,
    p_username         IN      VARCHAR2 default null,
    p_threshold_executions IN    NATURAL  default 3,
    p_threshold_sharable_mem IN  NATURAL  default 1000,
    p_parallel_degree  IN      NATURAL  default 1);
```

### Parameters

**Table 101-2 COMPILE\_FROM\_REMOTE Procedure Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p_db_link                | Database link to the source name (mandatory). The database link pointing to the instance that will be used for extracting the SQL statements. The user must have the role <code>SELECT_ON_CATALOG</code> at the source instance. For improved security, the connection may use a password file or LDAP authentication. The database link is mandatory only for releases with <code>dbms_libcache\$def.ACCESS_METHOD = DB_LINK_METHOD</code> .                                                                                                                                                                                                                                                |
| p_instance_name          | (Reserved for future use). The name of the instance that will be used for extracting the SQL statements. The instance name must be unique for all instances excluding the local instance. The name is not case sensitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| p_username               | Source username (default is all users). The name of the username that will be used for extracting the SQL statements. The username is an optional parameter that is used to ensure the parsing user id is the same as that on the source instance. For an application where users connect as a single user id, for example APPS, APPS is the parsing user id that is recorded in the shared pool. To select only SQL statements parsed by APPS, enter the string 'APPS' in this field. To also select statements executed by batch, repeat the executing the procedure with the schema owner, for example GL. If the username is supplied, it must be valid. The name is not case sensitive. |
| p_threshold_executions   | The lower bound for the number of executions, below which a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with executions, for example, greater than 3. The default value is 1. This means SQL statements that have never executed, including invalid SQL statements, will not be extracted.                                                                                                                                                                                                                                                                                                       |
| p_threshold_sharable_mem | The lower bound for the size of the shared memory consumed by the cursors on the source instance. Below this value a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with shared memory for example, greater than 10000 bytes.                                                                                                                                                                                                                                                                                                                                                                       |

**Table 101-2 (Cont.) COMPILE\_FROM\_REMOTE Procedure Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p_parallel_degree | The number of parallel jobs that execute to complete the parse operation. These tasks are spawned as parallel jobs against a sub-range of the SQL statements selected for parsing. This parameter is reserved for parallel compile jobs which are currently not implemented. |

# DBMS\_LOB

The `DBMS_LOB` package provides subprograms to operate on `BLOBs`, `CLOBs`, `NCLOBs`, `BFILEs`, and temporary `LOBs`. You can use `DBMS_LOB` to access and manipulate specific parts of a `LOB` or complete `LOBs`.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Datatypes](#)
- [Operational Notes](#)
- [Rules and Limits](#)
- [Exceptions](#)
- [Summary of DBMS\\_LOB Subprograms](#)

## See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide*

## 102.1 DBMS\_LOB Overview

`DBMS_LOB` can read and modify `BLOBs`, `CLOBs`, and `NCLOBs`; it provides read-only operations for `BFILEs`. The bulk of the `LOB` operations are provided by this package.

## 102.2 DBMS\_LOB Deprecated Subprograms

The `DBMS_LOB.LOADFROMFILE` program is deprecated from the `DBMS_LOB` package in Oracle Database 12c release 12.2

## Note:

Oracle recommends that do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

Use `DBMS_LOB.LoadClobFromFile` or `DBMS_LOB.LoadBlobFromFile` instead.

## 102.3 DBMS\_LOB Security Model

This package must be created under SYS. Operations provided by this package are performed under the current calling user, not under the package owner SYS.

Any DBMS\_LOB subprogram called from an anonymous PL/SQL block is executed using the privileges of the current user. Any DBMS\_LOB subprogram called from a stored procedure is executed using the privileges of the owner of the stored procedure.

When creating the procedure, users can set the AUTHID to indicate whether they want definer's rights or invoker's rights. For example:

```
CREATE PROCEDURE proc1 AUTHID DEFINER ...
```

or

```
CREATE PROCEDURE proc1 AUTHID CURRENT_USER ...
```

### See Also:

For more information on AUTHID and privileges, see *Oracle Database PL/SQL Language Reference*

You can provide secure access to BFILEs using the DIRECTORY feature discussed in BFILENAME function in the *Oracle Database SecureFiles and Large Objects Developer's Guide* and the *Oracle Database SQL Language Reference*.

For information about the security model pertaining to temporary LOBs, see [Operational Notes](#).

## 102.4 DBMS\_LOB Constants

This topic describes the constants used by the DBMS\_LOB package

These are shown in following tables:

- [Table 102-1](#)
- [Table 102-2](#)
- [Table 102-3](#)
- [Table 102-4](#)
- [Table 102-5](#)
- [Table 102-6](#)

**Table 102-1 DBMS\_LOB Constants - Basic**

| Constant | Type        | Value | Description                            |
|----------|-------------|-------|----------------------------------------|
| CALL     | PLS_INTEGER | 12    | Create the TEMP LOB with call duration |

**Table 102-1 (Cont.) DBMS\_LOB Constants - Basic**

| Constant      | Type           | Value                | Description                               |
|---------------|----------------|----------------------|-------------------------------------------|
| FILE_READONLY | BINARY_INTEGER | 0                    | Open the specified BFILE read-only        |
| LOB_READONLY  | BINARY_INTEGER | 0                    | Open the specified LOB read-only          |
| LOB_READWRITE | BINARY_INTEGER | 1                    | Open the specified LOB read-write         |
| LOBMAXSIZE    | INTEGER        | 18446744073709551615 | Maximum size of a LOB in bytes            |
| SESSION       | PLS_INTEGER    | 10                   | Create the TEMP LOB with session duration |

**Table 102-2 DBMS\_LOB Constants - Option Types**

| Constant        | Definition     | Value | Description                                     |
|-----------------|----------------|-------|-------------------------------------------------|
| OPT_COMPRESS    | BINARY_INTEGER | 1     | Set/Get the SECUREFILE compress option value    |
| OPT_DEDUPLICATE | BINARY_INTEGER | 4     | Set/Get the SECUREFILE Deduplicate option value |
| OPT_ENCRYPT     | BINARY_INTEGER | 2     | Get the SECUREFILE encrypt option value         |

**Table 102-3 DBMS\_LOB Constants - Option Values**

| Constant        | Definition     | Value | Description                                                                                                                       |
|-----------------|----------------|-------|-----------------------------------------------------------------------------------------------------------------------------------|
| COMPRESS_OFF    | BINARY_INTEGER | 0     | For <a href="#">SETOPTIONS Procedures</a> , set compress off; for <a href="#">GETOPTIONS Functions</a> , compress is off          |
| COMPRESS_ON     | BINARY_INTEGER | 1     | For <a href="#">SETOPTIONS Procedures</a> , set compress on; for <a href="#">GETOPTIONS Functions</a> , compress is on            |
| DEDUPLICATE_OFF | BINARY_INTEGER | 0     | For <a href="#">SETOPTIONS Procedures</a> , set deduplicate is off; for <a href="#">GETOPTIONS Functions</a> , deduplicate is off |
| DEDUPLICATE_ON  | BINARY_INTEGER | 4     | For <a href="#">SETOPTIONS Procedures</a> , set deduplicate is on; for <a href="#">GETOPTIONS Functions</a> , deduplicate is on   |
| ENCRYPT_OFF     | BINARY_INTEGER | 0     | For <a href="#">GETOPTIONS Functions</a> , encrypt is off                                                                         |
| ENCRYPT_ON      | BINARY_INTEGER | 2     | For <a href="#">GETOPTIONS Functions</a> , encrypt is on                                                                          |

**Table 102-4 DBMS\_LOB Constants - DBFS State Value Types**

| Constant        | Definition  | Value | Description                 |
|-----------------|-------------|-------|-----------------------------|
| DBFS_LINK_NEVER | PLS_INTEGER | 0     | LOB has never been archived |

**Table 102-4 (Cont.) DBMS\_LOB Constants - DBFS State Value Types**

| Constant      | Definition  | Value | Description                                             |
|---------------|-------------|-------|---------------------------------------------------------|
| DBFS_LINK_NO  | PLS_INTEGER | 2     | LOB was archived, but as been read back in to the RDBMS |
| DBFS_LINK_YES | PLS_INTEGER | 1     | LOB is currently archived                               |

**Table 102-5 DBMS\_LOB Constants - DBFS Cache Flags**

| Constant          | Definition  | Value | Description                                                                         |
|-------------------|-------------|-------|-------------------------------------------------------------------------------------|
| DBFS_LINK_CACHE   | PLS_INTEGER | 1     | Put the LOB data to the archive, but keep the data in the RDBMS as a cached version |
| DBFS_LINK_NOCACHE | PLS_INTEGER | 0     | Put the LOB data to the archive, and remove the data from the RDBMS.                |

**Table 102-6 DBMS\_LOB Constants - Miscellaneous**

| Constant                | Definition  | Value | Description                                                |
|-------------------------|-------------|-------|------------------------------------------------------------|
| CONTENTTYPE_MAX_SIZE    | PLS_INTEGER | 128   | Maximum number of bytes allowed in the content type string |
| DBFS_LINK_PATH_MAX_SIZE | PLS_INTEGER | 1024  | The maximum length of DBFS pathnames                       |

## 102.5 DBMS\_LOB Datatypes

The table in this topic describes the datatypes used by DBMS\_LOB.

**Table 102-7 Datatypes Used by DBMS\_LOB**

| Type     | Description                                                                            |
|----------|----------------------------------------------------------------------------------------|
| BLOB     | Source or destination binary LOB.                                                      |
| RAW      | Source or destination RAW buffer (used with BLOB).                                     |
| CLOB     | Source or destination character LOB (including NCLOB).                                 |
| VARCHAR2 | Source or destination character buffer (used with CLOB and NCLOB).                     |
| INTEGER  | Specifies the size of a buffer or LOB, the offset into a LOB, or the amount to access. |
| BFILE    | Large, binary object stored outside the database.                                      |

The DBMS\_LOB package defines no special types.

An NCLOB is a CLOB for holding fixed-width and varying-width, multibyte national character sets.

The clause ANY\_CS in the specification of DBMS\_LOB subprograms for CLOBs enables the CLOB type to accept a CLOB or NCLOB locator variable as input.

## 102.6 DBMS\_LOB Operational Notes

All `DBMS_LOB` subprograms work based on LOB locators. For the successful completion of `DBMS_LOB` subprograms, you must provide an input locator that represents a LOB that already exists in the database tablespaces or external file system.

See also Chapter 1 of *Oracle Database SecureFiles and Large Objects Developer's Guide*

Starting from 12.2 release, you can select a persistent LOB locator from a remote table into a local variable. The remote column can be of type BLOB, CLOB, or NCLOB. You cannot select `BFILE` from a remote table. The LOB variable that refers to the LOB value in a remote table is called a remote locator.

All the `DBMS_LOB` APIs other than the ones that are meant for BFILES will now accept and support operations on remote LOB locators. All the APIs that take in two locators must have both LOBs collocated at one database.

### See Also:

*Distributed LOBs* chapter in *Oracle Database SecureFiles and Large Objects Developer's Guide*.

To use LOBs in your database, you must first use SQL data definition language (DDL) to define the tables that contain LOB columns.

- Internal LOBs
- External LOBs
- Temporary LOBs

### Internal LOBs

To populate your table with internal LOBs after LOB columns are defined in a table, you use the SQL data manipulation language (DML) to initialize or populate the locators in the LOB columns.

### External LOBs

For an external LOB (BFILE) to be represented by a LOB locator, you must:

- Ensure that a `DIRECTORY` object representing a valid, existing physical directory has been defined, and that physical files (the LOBs you plan to add) exist with read permission for the database. If your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format.
- Pass the `DIRECTORY` object and the filename of the external LOB you are adding to the `BFILENAME` function to create a LOB locator for your external LOB.

Once you have completed these tasks, you can insert or update a row containing a LOB column using the specified LOB locator.

After the LOBs are defined and created, you can then `SELECT` from a LOB locator into a local PL/SQL LOB variable and use this variable as an input parameter to `DBMS_LOB` for access to the LOB value.

For details on the different ways to do this, See *Oracle Database SecureFiles and Large Objects Developer's Guide*

## Temporary LOBs

The database supports the definition, creation, deletion, access, and update of temporary LOBs. Your temporary tablespace stores the temporary LOB data. Temporary LOBs are not permanently stored in the database. Their purpose is mainly to perform transformations on LOB data.

For temporary LOBs, you must use the OCI, PL/SQL, or another programmatic interface to create or manipulate them. Temporary LOBs can be either BLOBs, CLOBs, or NCLOBs.

A temporary LOB is empty when it is created. By default, all temporary LOBs are deleted at the end of the session in which they were created. If a process dies unexpectedly or if the database crashes, then temporary LOBs are deleted, and the space for temporary LOBs is freed.

There is also an interface to let you group temporary LOBs together into a logical bucket. The duration represents this logical store for temporary LOBs. Each temporary LOB can have separate storage characteristics, such as `CACHE/ NOCACHE`. There is a default store for every session into which temporary LOBs are placed if you don't specify a specific duration. Additionally, you are able to perform a free operation on durations, which causes all contents in a duration to be freed.

There is no support for consistent read (CR), undo, backup, parallel processing, or transaction management for temporary LOBs. Because CR and roll backs are not supported for temporary LOBs, you must free the temporary LOB and start over again if you encounter an error.

Because CR, undo, and versions are not generated for temporary LOBs, there is potentially a performance impact if you assign multiple locators to the same temporary LOB. Semantically, each locator should have its own copy of the temporary LOB.

A copy of a temporary LOB is created if the user modifies the temporary LOB while another locator is also pointing to it. The locator on which a modification was performed now points to a new copy of the temporary LOB. Other locators no longer see the same data as the locator through which the modification was made. A deep copy was not incurred by permanent LOBs in these types of situations, because CR snapshots and version pages enable users to see their own versions of the LOB cheaply.

You can gain pseudo-REF semantics by using pointers to locators in OCI and by having multiple pointers to locators point to the same temporary LOB locator, if necessary. In PL/SQL, you must avoid using more than one locator for each temporary LOB. The temporary LOB locator can be passed by reference to other procedures.

Because temporary LOBs are not associated with any table schema, there are no meanings to the terms in-row and out-of-row temporary LOBs. Creation of a temporary LOB instance by a user causes the engine to create and return a locator to the LOB data. The PL/SQL `DBMS_LOB` package, PRO\*C/C++, OCI, and other programmatic interfaces operate on temporary LOBs through these locators just as they do for permanent LOBs.

There is no support for client side temporary LOBs. All temporary LOBs reside in the server.

Temporary LOBs do not support the `EMPTY_BLOB` or `EMPTY_CLOB` functions that are supported for permanent LOBs. The `EMPTY_BLOB` function specifies the fact that the LOB is initialized, but not populated with any data.

A temporary LOB instance can only be destroyed by using OCI or the `DBMS_LOB` package by using the appropriate `FREETEMPORARY` or `OCIDurationEnd` statement.

A temporary LOB instance can be accessed and modified using appropriate OCI and `DBMS_LOB` statements, just as for regular permanent internal LOBs. To make a temporary LOB permanent, you must explicitly use the OCI or `DBMS_LOB COPY` command, and copy the temporary LOB into a permanent one.

Security is provided through the LOB locator. Only the user who created the temporary LOB is able to see it. Locators are not expected to be able to pass from one user's session to another. Even if someone did pass a locator from one session to another, they would not access the temporary LOBs from the original session. Temporary LOB lookup is localized to each user's own session. Someone using a locator from somewhere else is only able to access LOBs within his own session that have the same LOB ID. Users should not try to do this, but if they do, they are not able to affect anyone else's data.

The database keeps track of temporary LOBs for each session in a `v$` view called `V$TEMPORARY_LOBS`, which contains information about how many temporary LOBs exist for each session. `v$` views are for DBA use. From the session, the database can determine which user owns the temporary LOBs. By using `V$TEMPORARY_LOBS` in conjunction with `DBA_SEGMENTS`, a DBA can see how much space is being used by a session for temporary LOBs. These tables can be used by DBAs to monitor and guide any emergency cleanup of temporary space used by temporary LOBs.

The following notes are specific to temporary LOBs:

1. All functions in `DBMS_LOB` return `NULL` if any of the input parameters are `NULL`. All procedures in `DBMS_LOB` raise an exception if the LOB locator is input as `NULL`.
2. Operations based on `CLOBs` do not verify if the character set IDs of the parameters (`CLOB` parameters, `VARCHAR2` buffers and patterns, and so on) match. It is the user's responsibility to ensure this.
3. Data storage resources are controlled by the DBA by creating different temporary tablespaces. DBAs can define separate temporary tablespaces for different users, if necessary.

## 102.7 DBMS\_LOB Rules and Limits

This topic describes general `DBMS_LOB` rules and limits, rules and limits specific to external files (BFILES), and maximum LOB and buffer sizes.

### General Rules and Limits

- Oracle Database does not support constraints on columns or attributes whose type is a LOB, with the following exception: `NOT NULL` constraints are supported for a LOB column or attribute.
- The following rules apply in the specification of subprograms in this package:
  - `newlen`, `offset`, and `amount` parameters for subprograms operating on `BLOBs` and `BFILES` must be specified in terms of *bytes*.

- `newlen`, `offset`, and `amount` parameters for subprograms operating on CLOBs must be specified in terms of *characters*.

In multi-byte character sets, it is not possible to interpret these offsets correctly. As a result, `SUBSTR` raises the following error: `ORA-22998: CLOB or NCLOB in multibyte character set not supported`.

- A subprogram raises an `INVALID_ARGVAL` exception if the following restrictions are not followed in specifying values for parameters (unless otherwise specified):
  1. Only positive, absolute offsets from the beginning of LOB data are permitted: Negative offsets from the tail of the LOB are not permitted.
  2. Only positive, nonzero values are permitted for the parameters that represent size and positional quantities, such as `amount`, `offset`, `newlen`, `nth`, and so on. Negative offsets and ranges observed in SQL string functions and operators are not permitted.
  3. The value of `offset`, `amount`, `newlen`, `nth` must not exceed the value `lobmaxsize` 18446744073709551615 ( $2^{64}$ ) in any `DBMS_LOB` subprogram.
  4. For CLOBs consisting of fixed-width multibyte characters, the maximum value for these parameters must not exceed  $(lobmaxsize/character\_width\_in\_bytes)$  characters.

For example, if the CLOB consists of 2-byte characters, such as:

```
JA16SJISFIXED
```

Then, the maximum `amount` value should not exceed:

```
18446744073709551615/2 = 9223372036854775807
```

- PL/SQL language specifications stipulate an upper limit of 32767 bytes (not characters) for `RAW` and `VARCHAR2` parameters used in `DBMS_LOB` subprograms. For example, if you declare a variable to be:

```
charbuf VARCHAR2(3000)
```

Then, `charbuf` can hold 3000 single byte characters or 1500 2-byte fixed width characters. This has an important consequence for `DBMS_LOB` subprograms for CLOBs and NCLOBs.

- The `%CHARSET` clause indicates that the form of the parameter with `%CHARSET` must match the form of the `ANY_CS` parameter to which it refers.

For example, in `DBMS_LOB` subprograms that take a `VARCHAR2` buffer parameter, the form of the `VARCHAR2` buffer must match the form of the CLOB parameter. If the input LOB parameter is of type `NCLOB`, then the buffer must contain `NCHAR` data. Conversely, if the input LOB parameter is of type `CLOB`, then the buffer must contain `CHAR` data.

For `DBMS_LOB` subprograms that take two CLOB parameters, both CLOB parameters must have the same form; that is, they must both be `NCLOBs`, or they must both be `CLOBs`.

- If the value of `amount` plus the `offset` exceeds the maximum LOB size allowed by the database, then access exceptions are raised.

Under these input conditions, read subprograms, such as `READ`, `COMPARE`, `INSTR`, and `SUBSTR`, read until End of Lob/File is reached. For example, for a `READ` operation on a BLOB or BFILE, if the user specifies offset value of 3 GB and an amount value of 2 GB on a LOB that is 4GB in size, then `READ` returns only 1GB (4GB-3GB) bytes.

- Functions with `NULL` or invalid input values for parameters return a `NULL`. Procedures with `NULL` values for destination LOB parameters raise exceptions.

- Operations involving patterns as parameters, such as `COMPARE`, `INSTR`, and `SUBSTR` do not support regular expressions or special matching characters (such as `%` in the `LIKE` operator in SQL) in the `pattern` parameter or substrings.
- The End Of LOB condition is indicated by the `READ` procedure using a `NO_DATA_FOUND` exception. This exception is raised only upon an attempt by the user to read beyond the end of the LOB. The `READ` buffer for the last read contains 0 bytes.
- For consistent LOB updates, you must lock the row containing the destination LOB before making a call to any of the procedures (mutators) that modify LOB data.
- Unless otherwise stated, the default value for an `offset` parameter is 1, which indicates the first byte in the `BLOB` or `BFILE` data, and the first character in the `CLOB` or `NCLOB` value. No default values are specified for the `amount` parameter — you must input the values explicitly.
- You must lock the row containing the destination internal LOB before calling any subprograms that modify the LOB, such as `APPEND`, `COPY`, `ERASE`, `TRIM`, or `WRITE`. These subprograms do not implicitly lock the row containing the LOB.

### Rules and Limits Specific to External Files (BFILES)

- The subprograms `COMPARE`, `INSTR`, `READ`, `SUBSTR`, `FILECLOSE`, `FILECLOSEALL` and `LOADFROMFILE` operate only on an *opened* `BFILE` locator; that is, a successful `FILEOPEN` call must precede a call to any of these subprograms.
- For the functions `FILEEXISTS`, `FILEGETNAME` and `GETLENGTH`, a file's open/close status is unimportant; however, the file must exist physically, and you must have adequate privileges on the `DIRECTORY` object and the file.
- `DBMS_LOB` does not support any concurrency control mechanism for `BFILE` operations.
- In the event of several open files in the session whose closure has not been handled properly, you can use the `FILECLOSEALL` subprogram to close all files opened in the session and resume file operations from the beginning.
- If you are the creator of a `DIRECTORY`, or if you have system privileges, then use the `CREATE` OR `REPLACE`, `DROP`, and `REVOKE` statements in SQL with extreme caution.

If you, or other grantees of a particular directory object, have several open files in a session, then any of the preceding commands can adversely affect file operations. In the event of such abnormal termination, your only choice is to invoke a program or anonymous block that calls `FILECLOSEALL`, reopen your files, and restart your file operations.

- All files opened during a user session are implicitly closed at the end of the session. However, Oracle strongly recommends that you close the files after *both* normal and abnormal termination of operations on the `BFILE`.

In the event of normal program termination, proper file closure ensures that the number of files that are open simultaneously in the session remains less than `SESSION_MAX_OPEN_FILES`.

In the event of abnormal program termination from a PL/SQL program, it is imperative that you provide an exception handler that ensures closure of all files opened in that PL/SQL program. This is necessary because after an exception occurs, only the exception handler has access to the `BFILE` variable in its most current state.

After the exception transfers program control outside the PL/SQL program block, all references to the open `BFILE`s are lost. The result is a larger open file count which may or may not exceed the `SESSION_MAX_OPEN_FILES` value.

For example, consider a READ operation past the end of the BFILE value, which generates a NO\_DATA\_FOUND exception:

```
-- This assumes a directory 'DDD' whose path is already known
DECLARE
    fil BFILE:= bfilename('DDD', 'filename.foo');
    pos INTEGER;
    amt BINARY_INTEGER;
    buf RAW(40);
BEGIN
    SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
    dbms_lob.open(fil, dbms_lob.lob_readonly);
    amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := '';
    dbms_lob.read(fil, amt, pos, buf);
    dbms_output.put_line('Read F1 past EOF: '||
        utl_raw.cast_to_varchar2(buf));
    dbms_lob.close(fil);
END;

ORA-01403: no data found
ORA-06512: at "SYS.DBMS_LOB", line 373
ORA-06512: at line 10
```

After the exception has occurred, the BFILE locator variable file goes out of scope, and no further operations on the file can be done using that variable. Therefore, the solution is to use an exception handler:

```
DECLARE
    fil BFILE;
    pos INTEGER;
    amt BINARY_INTEGER;
    buf RAW(40);
BEGIN
    SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
    dbms_lob.open(fil, dbms_lob.lob_readonly);
    amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := '';
    dbms_lob.read(fil, amt, pos, buf);
    dbms_output.put_line('Read F1 past EOF: '||
        utl_raw.cast_to_varchar2(buf));
    dbms_lob.close(fil);
exception
    WHEN no_data_found
    THEN
        BEGIN
            dbms_output.put_line('End of File reached. Closing file');
            dbms_lob.fileclose(fil);
            -- or dbms_lob.filecloseall if appropriate
        END;
END;
/

Statement processed.
End of File reached. Closing file
```

In general, you should ensure that files opened in a PL/SQL block using DBMS\_LOB are closed before normal or abnormal termination of the block.

### Maximum LOB Size

The maximum size for LOBs supported by the database is equal to the value of the blocksize of the tablespace the LOB column resides in times the value  $2^{32}-1$  (4294967295). This allows for a maximum LOB size ranging from 8 terabytes to 128 terabytes.

### Maximum Buffer Size

The maximum buffer size, 32767 bytes.

For BLOBs, where buffer size is expressed in bytes, the number of bytes cannot exceed 32767.

For CLOBs or NCLOBs, where buffer size is expressed in characters, the number of characters cannot result in a buffer larger than 32767 bytes. For example, if you are using fixed-width, two-byte characters, then specifying 20000 characters is an error ( $20000 \times 2 = 40000$ , which is greater than 32767).

## 102.8 DBMS\_LOB Exceptions

The table in the topic describes the exceptions for DBMS\_LOB.

**Table 102-8 DBMS\_LOB Exceptions**

| Exception            | Code  | Description                                                                                                                                                  |
|----------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACCESS_ERROR         | 22925 | You are trying to write too much data to the LOB: LOB size is limited to 4 gigabytes.                                                                        |
| BUFFERING_ENABLED    | 22279 | Cannot perform operation with LOB buffering enabled                                                                                                          |
| CONTENTTYPE_TOOLONG  | 43859 | The length of the contenttype string exceeds the defined maximum. Modify the length of the contenttype string and retry the operation.                       |
| CONTENTTYPEBUF_WRONG | 43862 | The length of the contenttype buffer is less than defined constant. Modify the length of the contenttype buffer and retry the operation.                     |
| INVALID_ARGVAL       | 21560 | The argument is expecting a non-NULL, valid value but the argument value passed in is NULL, invalid, or out of range.                                        |
| INVALID_DIRECTORY    | 22287 | The directory used for the current operation is not valid if being accessed for the first time, or if it has been modified by the DBA since the last access. |
| NO_DATA_FOUND        | 1403  | ENDOFLOB indicator for looping read operations. This is not a hard error.                                                                                    |
| NOEXIST_DIRECTORY    | 22285 | The directory leading to the file does not exist.                                                                                                            |
| NOPRIV_DIRECTORY     | 22286 | The user does not have the necessary access privileges on the directory or the file for the operation.                                                       |
| OPEN_TOOMANY         | 22290 | The number of open files has reached the maximum limit.                                                                                                      |
| OPERATION_FAILED     | 22288 | The operation attempted on the file failed.                                                                                                                  |
| QUERY_WRITE          | 14553 | Cannot perform a LOB write inside a query or PDML parallel execution server                                                                                  |
| SECUREFILE_BADLOB    | 43856 | A non-SECUREFILE LOB type was used in a SECUREFILE only call                                                                                                 |
| SECUREFILE_BADPARAM  | 43857 | An invalid argument was passed to a SECUREFILE subprogram                                                                                                    |

**Table 102-8 (Cont.) DBMS\_LOB Exceptions**

| Exception              | Code  | Description                                                               |
|------------------------|-------|---------------------------------------------------------------------------|
| SECUREFILE_MARKERASED  | 43861 | The mark provided to a <code>FRAGMENT_*</code> operation has been deleted |
| SECUREFILE_OUTOFBOUNDS | 43883 | Attempted to perform a <code>FRAGMENT_*</code> operation past the LOB end |
| UNOPENED_FILE          | 22289 | The file is not open for the required operation to be performed.          |
| VALUE_ERROR            | 6502  | PL/SQL error for invalid values to subprogram's parameters.               |

## 102.9 Summary of DBMS\_LOB Subprograms

This table lists the `DBMS_LOB` subprograms and briefly describes them.

**Table 102-9 DBMS\_LOB Package Subprograms**

| Subprogram                                        | Description                                                                                                                                                                                                                   |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">APPEND Procedures</a>                 | Appends the contents of the source LOB to the destination LOB                                                                                                                                                                 |
| <a href="#">CLOB2FILE Procedure</a>               | Writes the content of a CLOB into a file.                                                                                                                                                                                     |
| <a href="#">CLOSE Procedure</a>                   | Closes a previously opened internal or external LOB                                                                                                                                                                           |
| <a href="#">COMPARE Functions</a>                 | Compares two entire LOBs or parts of two LOBs                                                                                                                                                                                 |
| <a href="#">CONVERTTOBLOB Procedure</a>           | Reads character data from a source CLOB or NCLOB instance, converts the character data to the specified character, writes the converted data to a destination BLOB instance in binary format, and returns the new offsets     |
| <a href="#">CONVERTTOCLOB Procedure</a>           | Takes a source BLOB instance, converts the binary data in the source instance to character data using the specified character, writes the character data to a destination CLOB or NCLOB instance, and returns the new offsets |
| <a href="#">COPY Procedures</a>                   | Copies all, or part, of the source LOB to the destination LOB                                                                                                                                                                 |
| <a href="#">COPY_DBFS_LINK Procedures</a>         | Copies the DBFS Link in the source LOB to the destination LOB                                                                                                                                                                 |
| <a href="#">COPY_FROM_DBFS_LINK</a>               | Retrieves the data for the LOB from the DBFS store                                                                                                                                                                            |
| <a href="#">CREATETEMPORARY Procedures</a>        | Creates a temporary BLOB or CLOB and its corresponding index in the user's default temporary tablespace                                                                                                                       |
| <a href="#">DBFS_LINK_GENERATE_PATH Functions</a> | Returns a unique file path name for use in creating a DBFS Link                                                                                                                                                               |
| <a href="#">ERASE Procedures</a>                  | Erases all or part of a LOB                                                                                                                                                                                                   |
| <a href="#">FILECLOSE Procedure</a>               | Closes the file                                                                                                                                                                                                               |
| <a href="#">FILECLOSEALL Procedure</a>            | Closes all previously opened files                                                                                                                                                                                            |
| <a href="#">FILEEXISTS Function</a>               | Checks if the file exists on the server                                                                                                                                                                                       |
| <a href="#">FILEGETNAME Procedure</a>             | Gets the directory object name and file name                                                                                                                                                                                  |
| <a href="#">FILEISOPEN Function</a>               | Checks if the file was opened using the input BFILE locators                                                                                                                                                                  |
| <a href="#">FILEOPEN Procedure</a>                | Opens a file                                                                                                                                                                                                                  |
| <a href="#">FRAGMENT_DELETE Procedure</a>         | Deletes the data at the specified offset for the specified length from the LOB                                                                                                                                                |

**Table 102-9 (Cont.) DBMS\_LOB Package Subprograms**

| Subprogram                                     | Description                                                                                                                  |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">FRAGMENT_INSERT Procedures</a>     | Inserts the specified data (limited to 32K) into the LOB at the specified offset                                             |
| <a href="#">FRAGMENT_MOVE Procedure</a>        | Moves the amount of bytes (BLOB) or characters (CLOB/NCLOB) from the specified offset to the new offset specified            |
| <a href="#">FRAGMENT_REPLACE Procedures</a>    | Replaces the data at the specified offset with the specified data (not to exceed 32k)                                        |
| <a href="#">FREETEMPORARY Procedures</a>       | Frees the temporary BLOB or CLOB in the default temporary tablespace                                                         |
| <a href="#">GET_DBFS_LINK Functions</a>        | Returns the DBFS Link path associated with the specified SecureFile                                                          |
| <a href="#">GET_DBFS_LINK_STATE Procedures</a> | Retrieves the current DBFS Link state of the specified SecureFile                                                            |
| <a href="#">GETCHUNKSIZE Functions</a>         | Returns the amount of space used in the LOB chunk to store the LOB value                                                     |
| <a href="#">GETCONTENTTYPE Functions</a>       | Returns the content ID string previously set by means of the <a href="#">SETCONTENTTYPE Procedure</a>                        |
| <a href="#">GETLENGTH Functions</a>            | Gets the length of the LOB value                                                                                             |
| <a href="#">GETOPTIONS Functions</a>           | Obtains settings corresponding to the <code>option_type</code> field for a particular LOB                                    |
| <a href="#">GET_STORAGE_LIMIT Function</a>     | Returns the storage limit for LOBs in your database configuration                                                            |
| <a href="#">INSTR Functions</a>                | Returns the matching position of the <i>n</i> th occurrence of the pattern in the LOB                                        |
| <a href="#">ISOPEN Functions</a>               | Checks to see if the LOB was already opened using the input locator                                                          |
| <a href="#">ISREMOTE Function</a>              | Checks to see if the LOB is local to the database or if it belongs to a remote database.                                     |
| <a href="#">ISSECUREFILE Function</a>          | Returns TRUE if the LOB locator passed to is for a SecureFiles LOB, otherwise, returns FALSE                                 |
| <a href="#">ISTEMPORARY Functions</a>          | Checks if the locator is pointing to a temporary LOB                                                                         |
| <a href="#">LOADBLOBFROMFILE Procedure</a>     | Loads BFILE data into an internal BLOB                                                                                       |
| <a href="#">LOADCLOBFROMFILE Procedure</a>     | Loads BFILE data into an internal CLOB                                                                                       |
| <a href="#">LOADFROMFILE Procedure</a>         | Loads BFILE data into an internal LOB.<br>This procedure has been deprecated starting with Oracle Database 12c release 12.2. |
| <a href="#">MOVE_TO_DBFS_LINK Procedures</a>   | Writes the specified SecureFile data to the DBFS store                                                                       |
| <a href="#">OPEN Procedures</a>                | Opens a LOB (internal, external, or temporary) in the indicated mode                                                         |
| <a href="#">READ Procedures</a>                | Reads data from the LOB starting at the specified offset                                                                     |
| <a href="#">SET_DBFS_LINK Procedures</a>       | Links the specified SecureFile to the specified path name. It does not copy the data to the path                             |
| <a href="#">SETCONTENTTYPE Procedure</a>       | Sets the content type string for the data in the LOB                                                                         |
| <a href="#">SETOPTIONS Procedures</a>          | Enables CSCE features on a per-LOB basis, overriding the default LOB column settings                                         |

**Table 102-9 (Cont.) DBMS\_LOB Package Subprograms**

| Subprogram                             | Description                                                    |
|----------------------------------------|----------------------------------------------------------------|
| <a href="#">SUBSTR Functions</a>       | Returns part of the LOB value starting at the specified offset |
| <a href="#">TRIM Procedures</a>        | Trims the LOB value to the specified shorter length            |
| <a href="#">WRITE Procedures</a>       | Writes data to the LOB from a specified offset                 |
| <a href="#">WRITEAPPEND Procedures</a> | Writes a buffer to the end of a LOB                            |

## 102.9.1 APPEND Procedures

This procedure appends the contents of a source internal LOB to a destination LOB. It appends the complete source LOB.

### Syntax

```
DBMS_LOB.APPEND (  
    dest_lob IN OUT NOCOPY BLOB,  
    src_lob IN BLOB);  
  
DBMS_LOB.APPEND (  
    dest_lob IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    src_lob IN CLOB CHARACTER SET dest_lob%CHARSET);
```

### Parameters

**Table 102-10 APPEND Procedure Parameters**

| Parameter | Description                                                       |
|-----------|-------------------------------------------------------------------|
| dest_lob  | Locator for the internal LOB to which the data is to be appended. |
| src_lob   | Locator for the internal LOB from which the data is to be read.   |

### Exceptions

**Table 102-11 APPEND Procedure Exceptions**

| Exception         | Description                                                                               |
|-------------------|-------------------------------------------------------------------------------------------|
| VALUE_ERROR       | Either the source or the destination LOB is NULL.                                         |
| QUERY_WRITE       | Cannot perform a LOB write inside a query or PDML parallel execution server               |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB |

### Usage Notes

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

- If `APPEND` is called on a LOB that has been archived, it implicitly gets the LOB before the first byte is written
- If `APPEND` is called on a SecureFiles LOB that is a DBFS Link, an exception is thrown.

**See Also:**

## 102.9.2 CLOB2FILE Procedure

This procedure writes the content of a CLOB into a bfile. This procedure gets called from the deprecated `dbms_xslprocessor.clob2file` internally.

### Syntax

```
DBMS_LOB.CLOB2FILE(  
  src_cl      IN  CLOB,  
  file_loc    IN  VARCHAR2,  
  file_name    IN  VARCHAR2,  
  csid        IN  NUMBER    := 0,  
  open_mode   IN  VARCHAR2  := 'wb');
```

### Parameters

**Table 102-12 CLOB2FILE Procedure Parameters**

| Parameter              | Description                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>src_cl</code>    | Source CLOB locator to write into a file                                                                                                                                                                                                            |
| <code>file_loc</code>  | Directory object name where the file is located                                                                                                                                                                                                     |
| <code>file_name</code> | File name                                                                                                                                                                                                                                           |
| <code>csid</code>      | Character set id of the CLOB locator <ul style="list-style-type: none"><li>• Must be a valid Oracle id; otherwise returns an error</li><li>• If the value is 0, then the content of the output file will be in the database character set</li></ul> |
| <code>open_mode</code> | The mode to open the output file in. <ul style="list-style-type: none"><li>• <code>wb</code> — write byte mode, overwrites the file</li></ul> The default value is <code>wb</code> .                                                                |

## 102.9.3 CLOSE Procedure

This procedure closes a previously opened internal or external LOB.

### Syntax

```
DBMS_LOB.CLOSE (  
    lob_loc      IN OUT NOCOPY BLOB);  
  
DBMS_LOB.CLOSE (  
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);  
  
DBMS_LOB.CLOSE (  
    file_loc     IN OUT NOCOPY BFILE);
```

### Parameters

**Table 102-13** CLOSE Procedure Parameters

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Exceptions

No error is returned if the `BFILE` exists but is not opened. An error is returned if the LOB is not open.

### Usage Notes

`CLOSE` requires a round-trip to the server for both internal and external LOBs. For internal LOBs, `CLOSE` triggers other code that relies on the close call, and for external LOBs (`BFILE`s), `CLOSE` actually closes the server-side operating system file.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.4 COMPARE Functions

This function compares two entire LOBs or parts of two LOBs.

### Syntax

```
DBMS_LOB.COMPARE (
    lob_1          IN BLOB,
    lob_2          IN BLOB,
    amount         IN INTEGER := DBMS_LOB.LOBMAXSIZE,
    offset_1       IN INTEGER := 1,
    offset_2       IN INTEGER := 1)
RETURN INTEGER;

DBMS_LOB.COMPARE (
    lob_1          IN CLOB CHARACTER SET ANY_CS,
    lob_2          IN CLOB CHARACTER SET lob_1%CHARSET,
    amount         IN INTEGER := DBMS_LOB.LOBMAXSIZE,
    offset_1       IN INTEGER := 1,
    offset_2       IN INTEGER := 1)
RETURN INTEGER;

DBMS_LOB.COMPARE (
    lob_1          IN BFILE,
    lob_2          IN BFILE,
    amount         IN INTEGER,
    offset_1       IN INTEGER := 1,
    offset_2       IN INTEGER := 1)
RETURN INTEGER;
```

### Pragmas

```
pragma restrict_references (COMPARE, WNDS, WNPS, RNDS, RNPS);
```

### Parameters

**Table 102-14 COMPARE Function Parameters**

| Parameter | Description                                                                     |
|-----------|---------------------------------------------------------------------------------|
| lob_1     | LOB locator of first target for comparison.                                     |
| lob_2     | LOB locator of second target for comparison.                                    |
| amount    | Number of bytes (for BLOBs) or characters (for CLOBs/NCLOBs) to compare.        |
| offset_1  | Offset in bytes or characters on the first LOB (origin: 1) for the comparison.  |
| offset_2  | Offset in bytes or characters on the second LOB (origin: 1) for the comparison. |

### Return Values

- **INTEGER:** 0 if the comparison succeeds, nonzero if not.
- **NULL,** if any of `amount`, `offset_1` or `offset_2` is not a valid LOB offset value. A valid offset is within the range of 1 to `LOBMAXSIZE` inclusive.

### Usage Notes

- You can only compare LOBs of the same datatype (LOBs of BLOB type with other BLOBs, and CLOBs with CLOBs, and BFILEs with BFILEs). For BFILEs, the file must be already opened using a successful FILEOPEN operation for this operation to succeed.
- COMPARE returns 0 if the data exactly matches over the range specified by the offset and amount parameters. COMPARE returns -1 if the first CLOB is less than the second, and 1 if it is greater.
- For fixed-width *n*-byte CLOBs, if the input amount for COMPARE is specified to be greater than (DBMS\_LOB.LOBMAXSIZE/*n*), then COMPARE matches characters in a range of size (DBMS\_LOB.LOBMAXSIZE/*n*), or Max(length(clob1), length(clob2)), whichever is lesser.
- If COMPARE is called on any LOB that has been archived, it implicitly gets the LOB before the compare begins.
- If COMPARE () is called on a SecureFiles LOB that is a DBFS Link, the linked LOB is streamed from DBFS, if possible, otherwise an exception is thrown.

### Exceptions

**Table 102-15 COMPARE Function Exceptions for BFILE operations**

| Exception         | Description                                                                               |
|-------------------|-------------------------------------------------------------------------------------------|
| UNOPENED_FILE     | File was not opened using the input locator.                                              |
| NOEXIST_DIRECTORY | Directory does not exist.                                                                 |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.                                             |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.                                 |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file.                    |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB |

## 102.9.5 CONVERTTOBLOB Procedure

This procedure reads character data from a source CLOB or NCLOB instance, converts the character data to the character set you specify, writes the converted data to a destination BLOB instance in binary format, and returns the new offsets.

You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

### Syntax

```
DBMS_LOB.CONVERTTOBLOB(  
    dest_lob          IN OUT NOCOPY BLOB,
```

```

src_clob      IN      CLOB CHARACTER SET ANY_CS,
amount        IN      INTEGER,
dest_offset   IN OUT   INTEGER,
src_offset    IN OUT   INTEGER,
blob_csid     IN      NUMBER,
lang_context  IN OUT   INTEGER,
warning       OUT      INTEGER);

```

## Parameters

**Table 102-16 CONVERTTLOB Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dest_lob     | LOB locator of the destination LOB instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| src_clob     | LOB locator of the source LOB instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| amount       | Number of characters to convert from the source LOB.<br>If you want to copy the entire LOB, pass the constant DBMS_LOB.LOBMAXSIZE. If you pass any other value, it must be less than or equal to the size of the LOB.                                                                                                                                                                                                                                                                                                                                                 |
| dest_offset  | (IN) Offset in bytes in the destination LOB for the start of the write.<br>Specify a value of 1 to start at the beginning of the LOB.<br>(OUT) The new offset in bytes after the end of the write.                                                                                                                                                                                                                                                                                                                                                                    |
| src_offset   | (IN) Offset in characters in the source LOB for the start of the read.<br>(OUT) Offset in characters in the source LOB right after the end of the read.                                                                                                                                                                                                                                                                                                                                                                                                               |
| blob_csid    | Desired character set ID of the converted data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| lang_context | (IN) Language context, such as shift status, for the current conversion.<br>(OUT) The language context at the time when the current conversion is done.<br>This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero.                                                                                                                                                                                              |
| warning      | (OUT) Warning message. This parameter indicates when something abnormal happened during the conversion. You are responsible for checking the warning message.<br>Currently, the only possible warning is — inconvertible character. This occurs when the character in the source cannot be properly converted to a character in destination. The default replacement character (for example, '?') is used in place of the inconvertible character. The return value of this error message is defined as the constant warn_inconvertible_char in the DBMS_LOB package. |

## Usage Notes

### Preconditions

Before calling the CONVERTTLOB procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked. To lock the row, select the LOB using the FOR UPDATE clause of the SELECT statement.

### Constants and Defaults

All parameters are required. You must pass a variable for each `OUT` or `IN OUT` parameter. You must pass either a variable or a value for each `IN` parameter.

Table 102-17 gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values. These constants are defined in the `dbmslob.sql` package specification file.

**Table 102-17 DBMS\_LOB.CONVERTTLOB Typical Values**

| Parameter                 | Value                                      | Description                                      |
|---------------------------|--------------------------------------------|--------------------------------------------------|
| <code>amount</code>       | <code>LOBMAXSIZE</code> (IN)               | convert the entire file                          |
| <code>dest_offset</code>  | <code>1</code> (IN)                        | start from the beginning                         |
| <code>src_offset</code>   | <code>1</code> (IN)                        | start from the beginning                         |
| <code>blob_csid</code>    | <code>DEFAULT_CSID</code> (IN)             | default CSID, use same CSID as source LOB        |
| <code>lang_context</code> | <code>DEFAULT_LANG_CTX</code> (IN)         | default language context                         |
| <code>warning</code>      | <code>NO_WARNING</code> (OUT)              | no warning message, success                      |
|                           | <code>WARN_INCONVERTIBLE_CHAR</code> (OUT) | character in source cannot be properly converted |

#### General Notes

- You must specify the desired character set for the destination LOB in the `blob_csid` parameter. You can pass a zero value for `blob_csid`. When you do so, the database assumes that the desired character set is the same as the source LOB character set.
- You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The `amount` and `src_offset` values are in characters and the `dest_offset` is in bytes. To convert the entire LOB, you can specify `LOBMAXSIZE` for the `amount` parameter.
- `CONVERTTLOB` gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

#### Exceptions

Table 102-18 gives possible exceptions this procedure can throw. The first column lists the exception string and the second column describes the error conditions that can cause the exception.

**Table 102-18 CONVERTTLOB Procedure Exceptions**

| Exception                   | Description                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VALUE_ERROR</code>    | Any of the input parameters are <code>NULL</code> or <code>INVALID</code> .                                                                                                                                                                                                                                                               |
| <code>INVALID_ARGVAL</code> | One or more of the following: <ul style="list-style-type: none"><li>- <code>src_offset</code> or <code>dest_offset</code> &lt; 1.</li><li>- <code>src_offset</code> or <code>dest_offset</code> &gt; <code>LOBMAXSIZE</code>.</li><li>- <code>amount</code> &lt; 1.</li><li>- <code>amount</code> &gt; <code>LOBMAXSIZE</code>.</li></ul> |

## 102.9.6 CONVERTTOCLOB Procedure

This procedure takes a source BLOB instance, converts the binary data in the source instance to character data using the character set you specify, writes the character data to a destination CLOB or NCLOB instance, and returns the new offsets.

You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

### Syntax

```
DBMS_LOB.CONVERTTOCLOB (
    dest_lob      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    src_blob      IN              BLOB,
    amount        IN              INTEGER,
    dest_offset    IN OUT          INTEGER,
    src_offset     IN OUT          INTEGER,
    blob_csid      IN              NUMBER,
    lang_context   IN OUT          INTEGER,
    warning        OUT              INTEGER);
```

### Parameters

**Table 102-19 CONVERTTOCLOB Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dest_lob     | LOB locator of the destination LOB instance.                                                                                                                                                                                                                                                                                                                             |
| src_blob     | LOB locator of the source LOB instance.                                                                                                                                                                                                                                                                                                                                  |
| amount       | Number of bytes to convert from the source LOB.<br>If you want to copy the entire BLOB, pass the constant DBMS_LOB.LOBMAXSIZE. If you pass any other value, it must be less than or equal to the size of the BLOB.                                                                                                                                                       |
| dest_offset  | (IN) Offset in characters in the destination LOB for the start of the write. Specify a value of 1 to start at the beginning of the LOB.<br>(OUT) The new offset in characters after the end of the write. This offset always points to the beginning of the first complete character after the end of the write.                                                         |
| src_offset   | (IN) Offset in bytes in the source LOB for the start of the read.<br>(OUT) Offset in bytes in the source LOB right after the end of the read.                                                                                                                                                                                                                            |
| blob_csid    | The character set ID of the source data                                                                                                                                                                                                                                                                                                                                  |
| lang_context | (IN) Language context, such as shift status, for the current conversion.<br>(OUT) The language context at the time when the current conversion is done.<br>This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero. |

**Table 102-19 (Cont.) CONVERTTOCLOB Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warning   | <p>Warning message. This parameter indicates when something abnormal happened during the conversion. You are responsible for checking the warning message.</p> <p>Currently, the only possible warning is — inconvertible character. This occurs when the character in the source cannot be properly converted to a character in destination. The default replacement character (for example, '?') is used in place of the inconvertible character. The return value of this error message is defined as the constant <code>warn_inconvertible_char</code> in the <code>DBMS_LOB</code> package.</p> |

### Usage Notes

#### Preconditions

Before calling the `CONVERTTOCLOB` procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked before calling the `CONVERTTOCLOB` procedure. To lock the row, select the LOB using the `FOR UPDATE` clause of the `SELECT` statement.

#### Constants and Defaults

All parameters are required. You must pass a variable for each `OUT` or `IN OUT` parameter. You must pass either a variable or a value for each `IN` parameter.

[Table 102-20](#) gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values. These constants are defined in the `dbmslob.sql` package specification file.

**Table 102-20 DBMS\_LOB.CONVERTTOCLOB Typical Values**

| Parameter    | Value                                      | Description                                      |
|--------------|--------------------------------------------|--------------------------------------------------|
| amount       | <code>LOBMAXSIZE</code> (IN)               | convert the entire file                          |
| dest_offset  | 1 (IN)                                     | start from the beginning                         |
| src_offset   | 1 (IN)                                     | start from the beginning                         |
| csid         | <code>DEFAULT_CSID</code> (IN)             | default CSID, use destination CSID               |
| lang_context | <code>DEFAULT_LANG_CTX</code> (IN)         | default language context                         |
| warning      | <code>NO_WARNING</code> (OUT)              | no warning message, success                      |
|              | <code>WARN_INCONVERTIBLE_CHAR</code> (OUT) | character in source cannot be properly converted |

#### General Notes

- You must specify the desired character set for the source LOB in the `blob_csid` parameter. You can pass a zero value for `blob_csid`. When you do so, the database assumes that the desired character set is the same as the destination LOB character set.

- You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The `amount` and `src_offset` values are in bytes and the `dest_offset` is in characters. To convert the entire LOB, you can specify `LOBMAXSIZE` for the `amount` parameter.
- `CONVERTTOCLOB` gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

## Exceptions

**Table 102-21** `CONVERTTOCLOB` Procedure Exceptions

| Exception                   | Description                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VALUE_ERROR</code>    | Any of the input parameters are <code>NULL</code> or <code>INVALID</code> .                                                                                                                                                                                                                                                                    |
| <code>INVALID_ARGVAL</code> | One or more of the following: <ul style="list-style-type: none"> <li>- <code>src_offset</code> or <code>dest_offset</code> &lt; 1.</li> <li>- <code>src_offset</code> or <code>dest_offset</code> &gt; <code>LOBMAXSIZE</code>.</li> <li>- <code>amount</code> &lt; 1.</li> <li>- <code>amount</code> &gt; <code>LOBMAXSIZE</code>.</li> </ul> |

## 102.9.7 COPY Procedures

This procedure copies all, or a part of, a source internal LOB to a destination internal LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.

### Syntax

```
DBMS_LOB.COPY (
  dest_lob    IN OUT NOCOPY BLOB,
  src_lob     IN             BLOB,
  amount      IN             INTEGER,
  dest_offset IN             INTEGER := 1,
  src_offset  IN             INTEGER := 1);

DBMS_LOB.COPY (
  dest_lob    IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
  src_lob     IN             CLOB CHARACTER SET dest_lob%CHARSET,
  amount      IN             INTEGER,
  dest_offset IN             INTEGER := 1,
  src_offset  IN             INTEGER := 1);
```

## Parameters

**Table 102-22 COPY Procedure Parameters**

| Parameter                | Description                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------|
| <code>dest_lob</code>    | LOB locator of the copy target.                                                             |
| <code>src_lob</code>     | LOB locator of source for the copy.                                                         |
| <code>amount</code>      | Number of bytes (for BLOBs) or characters (for CLOBs) to copy.                              |
| <code>dest_offset</code> | Offset in bytes or characters in the destination LOB (origin: 1) for the start of the copy. |
| <code>src_offset</code>  | Offset in bytes or characters in the source LOB (origin: 1) for the start of the copy.      |

## Exceptions

**Table 102-23 COPY Procedure Exceptions**

| Exception                      | Description                                                                                                                                                                                                   |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VALUE_ERROR</code>       | Any of the input parameters are NULL or invalid.                                                                                                                                                              |
| <code>INVALID_ARGVAL</code>    | Either:<br>- <code>src_offset</code> or <code>dest_offset</code> < 1<br>- <code>src_offset</code> or <code>dest_offset</code> > LOBMAXSIZE<br>- <code>amount</code> < 1<br>- <code>amount</code> > LOBMAXSIZE |
| <code>QUERY_WRITE</code>       | Cannot perform a LOB write inside a query or PDML parallel execution server                                                                                                                                   |
| <code>BUFFERING_ENABLED</code> | Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB                                                                                                                     |

## Usage Notes

- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.
- It is not an error to specify an amount that exceeds the length of the data in the source LOB. Thus, you can specify a large amount to copy from the source LOB, which copies data from the `src_offset` to the end of the source LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

- Prior to copy, the source and destination LOBs are retrieved, if they are currently archived. For a complete over-write, the destination LOB is not retrieved.
- If the source LOB is a DBFS Link, the data is streamed from DBFS, if possible, otherwise an exception is thrown. If the destination LOB is a DBFS Link, an exception is thrown.

## 102.9.8 COPY\_DBFS\_LINK Procedures

This procedure copies the DBFS Link in the source LOB to the destination LOB.

### Syntax

```
DBMS_LOB.COPY_DBFS_LINK (
  lob_loc_dst   IN OUT BLOB,
  lob_loc_src   IN     BLOB,
  flags         IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);

DBMS_LOB.COPY_DBFS_LINK (
  lob_loc_dst   IN OUT CLOB CHARACTER SET ANY_CS,
  lob_loc_src   IN     CLOB CHARACTER SET ANY_CS,
  flags         IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);
```

### Parameters

**Table 102-24 COPY\_DBFS\_LINK Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lob_loc_dst | LOB to be made to reference the same storage data as lob_loc_src                                                                                                                                                                                                                             |
| lob_loc_src | LOB from which to copy the reference                                                                                                                                                                                                                                                         |
| flags       | Options to COPY_DBFS_LINK: <ul style="list-style-type: none"> <li>• DBFS_LINK_NOCACHE specifies to only copy the DBFS Link</li> <li>• DBFS_LINK_CACHE specifies to copy the DBFS Link and read the data into the database LOB specified by lob_loc_dst so that the data is cached</li> </ul> |

### Exceptions

**Table 102-25 COPY\_DBFS\_LINK Procedure Exceptions**

| Exception         | Description                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| SECUREFILE_BADLOB | Either lob_loc_src or lob_loc_dst is not a SECUREFILE                                                                                            |
| INVALID_ARGVAL    | lob_loc_src LOB has not been archived                                                                                                            |
| ORA-01555         | If the source LOB has been retrieved, never archived, or if the LOB has been migrated in and out (modified or not) since the locator was gotten. |

## 102.9.9 COPY\_FROM\_DBFS\_LINK

This procedure retrieves the archived SecureFiles LOB data from the DBFS HSM store and to the database.

### Syntax

```
DBMS_LOB.COPY_FROM_DBFS_LINK (  
    lob_loc          IN OUT BLOB);  
  
DBMS_LOB.COPY_FROM_DBFS_LINK (  
    lob_loc          IN OUT CLOB CHARACTER SET ANY_CS);
```

### Parameters

**Table 102-26 COPY\_FROM\_DBFS\_LINK Procedure Parameters**

| Parameter | Description                          |
|-----------|--------------------------------------|
| lob_loc   | LOB to be retrieved from the archive |

### Usage Note

COPY\_FROM\_DBFS\_LINK does not remove the underlying DBFS file.

If the LOB is successfully retrieved, COPY\_FROM\_DBFS\_LINK silently returns success.

### Exceptions

**Table 102-27 COPY\_FROM\_DBFS\_LINK Procedure Exceptions**

| Exception         | Description                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE                                                                                                                                            |
| ORA-01555         | If the LOB has already been retrieved and has been modified since retrieval, if the LOB has been migrated in and out (modified or not) since the locator was retrieved |

## 102.9.10 CREATETEMPORARY Procedures

This procedure creates a temporary BLOB or CLOB and its corresponding index in your default temporary tablespace.

### Syntax

```
DBMS_LOB.CREATETEMPORARY (  
    lob_loc IN OUT NOCOPY BLOB,  
    cache  IN              BOOLEAN,  
    dur     IN              PLS_INTEGER := DBMS_LOB.SESSION);  
  
DBMS_LOB.CREATETEMPORARY (  
    lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    cache  IN              BOOLEAN,  
    dur     IN              PLS_INTEGER := 10);
```

## Parameters

**Table 102-28 CREATETEMPORARY Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> .                                                                                                                                           |
| cache     | Specifies if LOB should be read into buffer cache or not.                                                                                                                                                            |
| dur       | 1 of 2 predefined duration values (SESSION or CALL) which specifies a hint as to whether the temporary LOB is cleaned up at the end of the session or call.<br>If dur is omitted, then the session duration is used. |

### See Also:

- *Oracle Database PL/SQL Language Reference* for more information about NOCOPY and passing temporary lobbs as parameters

## 102.9.11 DBFS\_LINK\_GENERATE\_PATH Functions

This subprogram returns a unique file path name for use in creating a DBFS Link.

### Syntax

```
DBMS_LOB.DBFS_LINK_GENERATE_PATH (
    lob_loc      IN BLOB,
    storage_dir  IN VARCHAR2)
RETURN VARCHAR2;

DBMS_LOB.DBFS_LINK_GENERATE_PATH (
    lob_loc      IN CLOB CHARACTER SET ANY_CS,
    storage_dir  IN VARCHAR2)
RETURN VARCHAR2;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES (dbfs_link_generate_path,
    WNDS, RNDS, WNPS, RNPS);
```

## Parameters

**Table 102-29 DBFS\_LINK\_GENERATE\_PATH Function Parameters**

| Parameter   | Description                                                  |
|-------------|--------------------------------------------------------------|
| lob_loc     | LOB to be retrieved from DBFS                                |
| storage_dir | DBFS directory that will be the parent directory of the file |

## Exceptions

**Table 102-30 DBFS\_LINK\_GENERATE\_PATH Function Exceptions**

| Exception            | Description                 |
|----------------------|-----------------------------|
| SECUREFILE_WRONGTYPE | lob_loc is not a SECUREFILE |

## Usage Notes

Returns a globally unique file pathname that can be used for archiving. This is guaranteed to be globally unique across all calls to this function for different LOBs and versions of that LOB. It is always the same for the same LOB and version.

## 102.9.12 ERASE Procedures

This procedure erases an entire internal LOB or part of an internal LOB.

## Syntax

```
DBMS_LOB.ERASE (
    lob_loc          IN OUT NOCOPY BLOB,
    amount           IN OUT NOCOPY INTEGER,
    offset           IN             INTEGER := 1);

DBMS_LOB.ERASE (
    lob_loc          IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    amount           IN OUT NOCOPY INTEGER,
    offset           IN             INTEGER := 1);
```

## Parameters

**Table 102-31 ERASE Procedure Parameters**

| Parameter | Description                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------|
| lob_loc   | Locator for the LOB to be erased. For more information, see <a href="#">Operational Notes</a> .       |
| amount    | Number of bytes (for BLOBs or BFILES) or characters (for CLOBs or NCLOBs) to be erased.               |
| offset    | Absolute offset (origin: 1) from the beginning of the LOB in bytes (for BLOBs) or characters (CLOBs). |

## Usage Notes

- When data is erased from the middle of a LOB, zero-byte fillers or spaces are written for BLOBs or CLOBs respectively.
- The actual number of bytes or characters erased can differ from the number you specified in the `amount` parameter if the end of the LOB value is reached before erasing the specified number. The actual number of characters or bytes erased is returned in the `amount` parameter.
- ERASE gets the LOB if it is archived, unless the erase covers the entire LOB.
- If the LOB to be erased is a DBFS Link, an exception is thrown.

**Note:**

The length of the LOB is not decreased when a section of the LOB is erased. To decrease the length of the LOB value, see the "[TRIM Procedures](#)".

**Exceptions****Table 102-32 ERASE Procedure Exceptions**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| VALUE_ERROR       | Any input parameter is NULL.                                                           |
| INVALID_ARGVAL    | Either:<br>- amount < 1 or amount > LOBMAXSIZE<br>- offset < 1 or offset > LOBMAXSIZE  |
| QUERY_WRITE       | Cannot perform a LOB write inside a query or PDML parallel execution server            |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

**Usage Notes**

It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

**See Also:**

- "[TRIM Procedures](#)"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.13 FILECLOSE Procedure

This procedure closes a `BFILE` that has already been opened through the input locator.

### Note:

The database has only read-only access to `BFILEs`. This means that `BFILEs` cannot be written through the database.

### Syntax

```
DBMS_LOB.FILECLOSE (  
    file_loc IN OUT NOCOPY BFILE);
```

### Parameters

**Table 102-33 FILECLOSE Procedure Parameters**

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| file_loc  | Locator for the <code>BFILE</code> to be closed. |

### Exceptions

**Table 102-34 FILECLOSE Procedure Exceptions**

| Exception         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| VALUE_ERROR       | NULL input value for <code>file_loc</code> .                           |
| UNOPENED_FILE     | File was not opened with the input locator.                            |
| NOEXIST_DIRECTORY | Directory does not exist.                                              |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.                          |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.              |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file. |

### See Also:

- ["FILEOPEN Procedure"](#)
- ["FILECLOSEALL Procedure"](#)
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.14 FILECLOSEALL Procedure

This procedure closes all `BFILE`s opened in the session.

### Syntax

```
DBMS_LOB.FILECLOSEALL;
```

### Exceptions

**Table 102-35 FILECLOSEALL Procedure Exception**

| Exception                  | Description                             |
|----------------------------|-----------------------------------------|
| <code>UNOPENED_FILE</code> | No file has been opened in the session. |

### See Also:

- ["FILEOPEN Procedure"](#)
- ["FILECLOSE Procedure"](#)
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.15 FILEEXISTS Function

This function finds out if a specified `BFILE` locator points to a file that actually exists on the server's file system.

### Syntax

```
DBMS_LOB.FILEEXISTS (  
    file_loc    IN    BFILE)  
RETURN INTEGER;
```

### Pragmas

```
pragma restrict_references(FILEEXISTS, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-36 FILEEXISTS Function Parameter**

| Parameter             | Description                          |
|-----------------------|--------------------------------------|
| <code>file_loc</code> | Locator for the <code>BFILE</code> . |

## Return Values

**Table 102-37 FILEEXISTS Function Return Values**

| Return | Description                   |
|--------|-------------------------------|
| 0      | Physical file does not exist. |
| 1      | Physical file exists.         |

## Exceptions

**Table 102-38 FILEEXISTS Function Exceptions**

| Exception         | Description                                               |
|-------------------|-----------------------------------------------------------|
| NOEXIST_DIRECTORY | Directory does not exist.                                 |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.             |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened. |

### See Also:

- ["FILEISOPEN Function"](#).
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.16 FILEGETNAME Procedure

This procedure determines the directory object and filename, given a BFILE locator.

This function only indicates the directory object name and filename assigned to the locator, not if the physical file or directory actually exists.

The maximum constraint values for the `dir_alias` buffer is 30, and for the entire path name, it is 2000.

### Syntax

```
DBMS_LOB.FILEGETNAME (  
    file_loc    IN    BFILE,  
    dir_alias   OUT   VARCHAR2,  
    filename    OUT   VARCHAR2);
```

### Parameters

**Table 102-39 FILEGETNAME Procedure Parameters**

| Parameter              | Description           |
|------------------------|-----------------------|
| <code>file_loc</code>  | Locator for the BFILE |
| <code>dir_alias</code> | Directory object name |

**Table 102-39 (Cont.) FILEGETNAME Procedure Parameters**

| Parameter | Description       |
|-----------|-------------------|
| filename  | Name of the BFILE |

**Exceptions****Table 102-40 FILEGETNAME Procedure Exceptions**

| Exception      | Description                                      |
|----------------|--------------------------------------------------|
| VALUE_ERROR    | Any of the input parameters are NULL or INVALID. |
| INVALID_ARGVAL | dir_alias or filename are NULL.                  |

**See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.17 FILEISOPEN Function

This function finds out whether a BFILE was opened with the specified FILE locator.

**Syntax**

```
DBMS_LOB.FILEISOPEN (  
    file_loc IN BFILE)  
    RETURN INTEGER;
```

**Pragmas**

```
PRAGMA RESTRICT_REFERENCES(fileisopen, WNDS, RNDS, WNPS, RNPS);
```

**Parameters****Table 102-41 FILEISOPEN Function Parameter**

| Parameter | Description            |
|-----------|------------------------|
| file_loc  | Locator for the BFILE. |

**Return Values**

INTEGER: 0 = file is not open, 1 = file is open

**Usage Notes**

If the input FILE locator was never passed to the FILEOPEN procedure, then the file is considered not to be opened by this locator. However, a different locator may have this file open. In other words, openness is associated with a specific locator.

## Exceptions

**Table 102-42 FILEISOPEN Function Exceptions**

| Exception         | Description                                               |
|-------------------|-----------------------------------------------------------|
| NOEXIST_DIRECTORY | Directory does not exist.                                 |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.             |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened. |

### See Also:

- ["FILEEXISTS Function"](#)
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.18 FILEOPEN Procedure

This procedure opens a BFILE for read-only access. BFILE data may not be written through the database.

### Syntax

```
DBMS_LOB.FILEOPEN (
    file_loc  IN OUT NOCOPY  BFILE,
    open_mode IN              BINARY_INTEGER := file_readonly);
```

### Parameters

**Table 102-43 FILEOPEN Procedure Parameters**

| Parameter | Description               |
|-----------|---------------------------|
| file_loc  | Locator for the BFILE.    |
| open_mode | File access is read-only. |

## Exceptions

**Table 102-44 FILEOPEN Procedure Exceptions**

| Exception         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| VALUE_ERROR       | file_loc or open_mode is NULL.                                         |
| INVALID_ARGVAL    | open_mode is not equal to FILE_READONLY.                               |
| OPEN_TOOMANY      | Number of open files in the session exceeds session_max_open_files.    |
| NOEXIST_DIRECTORY | Directory associated with file_loc does not exist.                     |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.              |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file. |

## 102.9.19 FRAGMENT\_DELETE Procedure

This procedure deletes the data at the specified offset for the specified length from the LOB without having to rewrite all the data in the LOB following the specified offset.

### Syntax

```
DBMS_LOB.FRAGMENT_DELETE (  
    lob_loc      IN OUT NOCOPY BLOB,  
    amount       IN              INTEGER,  
    offset       IN              INTEGER);  
  
DBMS_LOB.FRAGMENT_DELETE (  
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    amount       IN              INTEGER,  
    offset       IN              INTEGER);
```

### Parameters

**Table 102-45** FRAGMENT\_DELETE Procedure Parameters

| Parameter | Description                                                                          |
|-----------|--------------------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> .           |
| amount    | Number of bytes (BLOB) or characters (CLOB/NCLOB) to be removed from the LOB         |
| offset    | Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the deletion |

### Exceptions

**Table 102-46** FRAGMENT\_DELETE Procedure Exceptions

| Exception              | Description                                                 |
|------------------------|-------------------------------------------------------------|
| INVALID_ARGVAL         | A parameter value was invalid                               |
| QUERY_WRITE            | Cannot perform operation during a query                     |
| BUFFERING_ENABLED      | Cannot perform operation with LOB buffering enabled         |
| SECUREFILE_BADLOB      | A non-SECUREFILE LOB was used in a SECUREFILE LOB only call |
| SECUREFILE_OUTOFBOUNDS | Attempted to perform a FRAGMENT_* operation past LOB end    |

## 102.9.20 FRAGMENT\_INSERT Procedures

This procedure inserts the specified data (limited to 32K) into the LOB at the specified offset.

### Syntax

```
DBMS_LOB.FRAGMENT_INSERT (
    lob_loc      IN OUT NOCOPY BLOB,
    amount       IN           INTEGER,
    offset       IN           INTEGER,
    buffer       IN           RAW);

DBMS_LOB.FRAGMENT_INSERT (
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    amount       IN           INTEGER,
    offset       IN           INTEGER,
    buffer       IN           VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

### Parameters

**Table 102-47** FRAGMENT\_INSERT Procedure Parameters

| Parameter | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> .            |
| amount    | Number of bytes (BLOB) or characters (CLOB/NCLOB) to be inserted into the LOB         |
| offset    | Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the insertion |
| buffer    | Data to insert into the LOB                                                           |

### Exceptions

**Table 102-48** FRAGMENT\_INSERT Procedure Exceptions

| Exception              | Description                                                 |
|------------------------|-------------------------------------------------------------|
| INVALID_ARGVAL         | A parameter value was invalid                               |
| QUERY_WRITE            | Cannot perform operation during a query                     |
| BUFFERING_ENABLED      | Cannot perform operation with LOB buffering enabled         |
| SECUREFILE_BADLOB      | A non-SECUREFILE LOB was used in a SECUREFILE LOB only call |
| SECUREFILE_OUTOFBOUNDS | Attempted to perform a FRAGMENT_* operation past LOB end    |

### Usage Notes

FRAGMENT\_INSERT gets the LOB, if necessary, before performing operations on the LOB.

## 102.9.21 FRAGMENT\_MOVE Procedure

This procedure moves the amount of bytes (BLOB) or characters (CLOB/NCLOB) from the specified offset to the new offset specified.

### Syntax

```
DBMS_LOB.FRAGMENT_MOVE (
    lob_loc      IN OUT NOCOPY BLOB,
    amount       IN          INTEGER,
    src_offset   IN          INTEGER,
    dest_offset  IN          INTEGER);

DBMS_LOB.FRAGMENT_MOVE (
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    amount       IN          INTEGER,
    src_offset   IN          INTEGER,
    dest_offset  IN          INTEGER);
```

### Parameters

**Table 102-49** FRAGMENT\_MOVE Procedure Parameters

| Parameter   | Description                                                                                 |
|-------------|---------------------------------------------------------------------------------------------|
| lob_loc     | LOB locator. For more information, see <a href="#">Operational Notes</a> .                  |
| amount      | Number of bytes (BLOB) or characters (CLOB/NCLOB) to be moved in the LOB                    |
| src_offset  | Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data    |
| dest_offset | Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to remove the data |

### Exceptions

**Table 102-50** FRAGMENT\_MOVE Procedure Exceptions

| Exception              | Description                                                 |
|------------------------|-------------------------------------------------------------|
| INVALID_ARGVAL         | A parameter value was invalid                               |
| QUERY_WRITE            | Cannot perform operation during a query                     |
| BUFFERING_ENABLED      | Cannot perform operation with LOB buffering enabled         |
| SECUREFILE_BADLOB      | A non-SECUREFILE LOB was used in a SECUREFILE LOB only call |
| SECUREFILE_OUTOFBOUNDS | Attempted to perform a FRAGMENT_* operation past LOB end    |

### Usage Notes

- All offsets are pre-move offsets.
- Offsets of more than 1 past the end of the LOB are not permitted.
- FRAGMENT\_MOVE gets the LOB, if necessary, before performing operations on the LOB.

## 102.9.22 FRAGMENT\_REPLACE Procedures

This procedure replaces the data at the specified offset with the specified data (not to exceed 32k).

### Syntax

```
DBMS_LOB.FRAGMENT_REPLACE (
    lob_loc      IN OUT NOCOPY BLOB,
    old_amount   IN          INTEGER,
    new_amount   IN          INTEGER,
    offset       IN          INTEGER,
    buffer       IN          RAW);

DBMS_LOB.FRAGMENT_REPLACE (
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  old_amount   IN
    INTEGER,
    new_amount   IN          INTEGER,
    offset       IN          INTEGER,
    buffer       IN          VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

### Parameters

**Table 102-51 FRAGMENT\_REPLACE Function Parameters**

| Parameter  | Description                                                                              |
|------------|------------------------------------------------------------------------------------------|
| lob_loc    | LOB locator. For more information, see <a href="#">Operational Notes</a> .               |
| old_amount | Number of bytes (BLOB) or characters (CLOB/NCLOB) to be replaced in the LOB              |
| new_amount | Number of bytes (BLOB) or characters (CLOB/NCLOB) to written to the LOB                  |
| offset     | Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data |
| buffer     | Data to insert into the LOB                                                              |

### Exceptions

**Table 102-52 FRAGMENT\_REPLACE Procedure Exceptions**

| Exception              | Description                                                 |
|------------------------|-------------------------------------------------------------|
| INVALID_ARGVAL         | A parameter value was invalid                               |
| QUERY_WRITE            | Cannot perform operation during a query                     |
| BUFFERING_ENABLED      | Cannot perform operation with LOB buffering enabled         |
| SECUREFILE_BADLOB      | A non-SECUREFILE LOB was used in a SECUREFILE LOB only call |
| SECUREFILE_OUTOFBOUNDS | Attempted to perform a FRAGMENT_* operation past LOB end    |

### Usage Notes

- Invoking this procedure is equivalent to deleting the old amount of bytes/characters at offset and then inserting the new amount of bytes/characters at offset.
- FRAGMENT\_REPLACE gets the LOB, if necessary, before performing operations on the LOB.

## 102.9.23 FREETEMPORARY Procedures

This procedure frees the temporary BLOB or CLOB in the default temporary tablespace.

### Syntax

```
DBMS_LOB.FREETEMPORARY (  
    lob_loc IN OUT NOCOPY BLOB);  
  
DBMS_LOB.FREETEMPORARY (  
    lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);
```

### Parameters

**Table 102-53 FREETEMPORARY Procedure Parameters**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Usage Notes

- When a new temporary LOB is created, and there is currently no temporary LOB in use with the same duration (session, call), a new temporary LOB segment is created. When the temporary LOB is freed, the space it consumed is released to the temporary segment. If there are no other temporary LOBs for the same duration, the temporary segment is also freed.
- After the call to FREETEMPORARY, the LOB locator that was freed is marked as invalid.
- If an invalid LOB locator is assigned to another LOB locator using `OCILOBLocatorAssign` in OCI or through an assignment operation in PL/SQL, then the target of the assignment is also freed and marked as invalid.

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.24 GET\_DBFS\_LINK Functions

This function returns the DBFS path name for the specified SecureFile LOB.

### Syntax

```
DBMS_LOB.GET_DBFS_LINK (  
    lob_loc IN BLOB,  
    storage_path OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),  
    lob_length OUT NUMBER);  
  
DBMS_LOB.GET_DBFS_LINK (  
    lob_loc IN CLOB CHARACTER SET ANY_CS,  
    storage_path OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),  
    lob_length OUT NUMBER);
```

## Parameters

**Table 102-54 GET\_DBFS\_LINK Function Parameters**

| Parameter    | Description                             |
|--------------|-----------------------------------------|
| lob_loc      | LOB to be retrieved from DBFS           |
| storage_path | Path where the LOB is stored in DBFS    |
| lob_length   | LOB length at the time of write to DBFS |

## Return Values

The Archive ID

## Exceptions

**Table 102-55 GET\_DBFS\_LINK Function Exceptions**

| Exception         | Description                                                                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE                                                                                                                                        |
| ORA-01555         | The LOB has already been retrieved and has been modified since retrieval or the LOB has been migrated in and out (modified or not) since the locator was retrieved |

## 102.9.25 GET\_DBFS\_LINK\_STATE Procedures

GET\_DBFS\_LINK\_STATE retrieves the current link state of the specified SecureFile.

### Syntax

```
DBMS_LOB.GET_DBFS_LINK_STATE (  
  lob_loc      IN BLOB,  
  storage_path OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),  
  state        OUT NUMBER,  
  cached       OUT BOOLEAN);
```

```
DBMS_LOB.GET_DBFS_LINK_STATE (  
  lob_loc      IN CLOB CHARACTER SET ANY_CS,  
  storage_path OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),  
  state        OUT NUMBER,  
  cached       OUT BOOLEAN);
```

## Parameters

**Table 102-56 GET\_DBFS\_LINK\_STATE Procedure Parameters**

| Parameter    | Description                                                           |
|--------------|-----------------------------------------------------------------------|
| lob_loc      | LOB to be retrieved from the archive                                  |
| storage_path | Path where the LOB is stored in the DBFS HSM store                    |
| state        | One of DBFS_LINK_NEVER, DBFS_LINK_NO or DBFS_LINK_YES                 |
| cached       | If the LOB is archived and the data was specified to be cached on put |

## Exceptions

**Table 102-57 GET\_DBFS\_LINK\_STATE Procedure Exceptions**

| Exception         | Description                 |
|-------------------|-----------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE |

## Usage Notes

- If the LOB has never been archived, state is set to DBMS\_LOB.DBFS\_LINK\_NEVER. If the LOB has been archived, state is set to DBMS\_LOB.DBFS\_LINK\_YES. If the LOB has been previously retrieved from the archive, state is set to DBFS\_LINK\_NO.
- If the LOB was archived, but the data was left in the RDBMS, cached is set to TRUE. If the data was removed after the link was created, cached is set to FALSE, and NULL if state is DBMS\_LOB.DBFS\_LINK\_NEVER.

## 102.9.26 GETCONTENTTYPE Functions

This procedure returns the content type string previously set by means of the SETCONTENTTYPE Procedure.

### Syntax

```
DBMS_LOB.GETCONTENTTYPE (  
    lob_loc IN BLOB)  
RETURN VARCHAR2;  
  
DBMS_LOB.GETCONTENTTYPE (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
RETURN VARCHAR2;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES (getcontenttype, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-58 GETCONTENTTYPE Function Parameters**

| Parameter | Description                               |
|-----------|-------------------------------------------|
| lob_loc   | LOB whose content type is to be retrieved |

### Return Values

The returned content type.

If the SecureFiles LOB does not have a contenttype associated with it, GETCONTENTTYPE () returns NULL.

## Exceptions

**Table 102-59** GETCONTENTTYPE Function Exceptions

| Exception         | Description                 |
|-------------------|-----------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE |

## Related Topics

- [SETCONTENTTYPE Procedure](#)  
This procedure sets the content type string for the data in the LOB.

## 102.9.27 GET\_STORAGE\_LIMIT Function

This function returns the LOB storage limit for the specified LOB.

### Syntax

```
DBMS_LOB.GET_STORAGE_LIMIT (  
    lob_loc  IN CLOB CHARACTER SET ANY_CS)  
RETURN INTEGER;  
  
DBMS_LOB.GET_STORAGE_LIMIT (  
    lob_loc  IN BLOB)  
RETURN INTEGER;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(get_storage_limit, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-60** GET\_STORAGE\_LIMIT Function Parameters

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Return Value

The value returned from this function is the maximum allowable size for specified LOB locator. For **BLOBS**, the return value depends on the block size of the tablespace the LOB resides in and is calculated as  $(2^{32})-1$  (4294967295) times the block size of the tablespace. For **CLOBs/NCLOBs**, the value returned is the  $(2^{32})-1$  (4294967295) times the block size of the tablespace divided by the character width of the **CLOB/NCLOB**.

### Usage

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for details on LOB storage limits

## 102.9.28 GETCHUNKSIZE Functions

When creating the table, you can specify the chunking factor, a multiple of tablespace blocks in bytes. This corresponds to the chunk size used by the LOB data layer when accessing or modifying the LOB value. Part of the chunk is used to store system-related information, and the rest stores the LOB value. This function returns the amount of space used in the LOB chunk to store the LOB value.

### Syntax

```
DBMS_LOB.GETCHUNKSIZE (  
    lob_loc IN BLOB)  
    RETURN INTEGER;  
  
DBMS_LOB.GETCHUNKSIZE (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
    RETURN INTEGER;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(getchunksize, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-61 GETCHUNKSIZE Function Parameters**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Return Values

The return value is a usable chunk size in bytes.

### Usage Notes

- With regard to basic LOB files, performance is improved if you enter read/write requests using a multiple of this chunk size. For writes, there is an added benefit, because LOB chunks are versioned, and if all writes are done on a chunk basis, then no extra or excess versioning is done or duplicated. You could batch up the `WRITE` until you have enough for a chunk, instead of issuing several `WRITE` calls for the same chunk.

These tactics of performance improvement do not apply to SecureFiles.

- Note that chunk size is independent of LOB type (`BLOB`, `CLOB`, `NCLOB`, Unicode or other character set).

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## Exceptions

**Table 102-62** GETCHUNKSIZE Procedure Exceptions

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

## 102.9.29 GETLENGTH Functions

This function gets the length of the specified LOB. The length in bytes or characters is returned.

The length returned for a `BFILE` includes the `EOF`, if it exists. Any 0-byte or space filler in the LOB caused by previous `ERASE` or `WRITE` operations is also included in the length count. The length of an empty internal LOB is 0.

### Syntax

```
DBMS_LOB.GETLENGTH (  
    lob_loc    IN  BLOB)  
    RETURN INTEGER;  
  
DBMS_LOB.GETLENGTH (  
    lob_loc    IN  CLOB    CHARACTER SET ANY_CS)  
    RETURN INTEGER;  
  
DBMS_LOB.GETLENGTH (  
    file_loc   IN  BFILE)  
    RETURN INTEGER;
```

### Pragmas

```
pragma restrict_references(GETLENGTH, WNDS, WNPS, RNDS, RNPS);
```

### Parameters

**Table 102-63** GETLENGTH Function Parameter

| Parameter | Description                                                  |
|-----------|--------------------------------------------------------------|
| file_loc  | The file locator for the LOB whose length is to be returned. |

### Return Values

The length of the LOB in bytes or characters as an `INTEGER`. `NULL` is returned if the input LOB is `NULL` or if the input `lob_loc` is `NULL`. An error is returned in the following cases for `BFILE`s:

- `lob_loc` does not have the necessary directory and operating system privileges
- `lob_loc` cannot be read because of an operating system read error

 **See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

**Exceptions****Table 102-64 GETLENGTH Procedure Exceptions**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

## 102.9.30 GETOPTIONS Functions

This function obtains compression, deduplication, and encryption settings corresponding to the `option_type` field for a particular LOB.

**Syntax**

```
DBMS_LOB.GETOPTIONS (
    lob_loc          IN      BLOB,
    option_types     IN      PLS_INTEGER)
RETURN PLS_INTEGER;

DBMS_LOB.GETOPTIONS (
    lob_loc          IN      CLOB CHARACTER SET ANY_CS,
    option_types     IN      PLS_INTEGER)
RETURN PLS_INTEGER;
```

**Parameters****Table 102-65 GETOPTIONS Function Parameter**

| Parameter   | Description                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------|
| lob_loc     | Locator for the LOB to be examined. For more information, see <a href="#">Operational Notes</a> . |
| option_type | See <a href="#">Table 102-2</a>                                                                   |

**Return Values**

The return values are a combination of `COMPRESS_ON`, `ENCRYPT_ON` and `DEDUPLICATE_ON` (see [Table 102-3](#)) depending on which option types (see [Table 102-2](#)) are passed in.

**Exceptions****Table 102-66 GETOPTIONS Procedure Exceptions**

| Exception      | Description                             |
|----------------|-----------------------------------------|
| INVALID_ARGVAL | A parameter value was invalid           |
| QUERY_WRITE    | Cannot perform operation during a query |

**Table 102-66 (Cont.) GETOPTIONS Procedure Exceptions**

| Exception         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled         |
| SECUREFILE_BADLOB | A non-SECUREFILE LOB was used in a SECUREFILE LOB only call |

### Usage Notes

You cannot turn compression or deduplication on or off for a SecureFile column that does not have those features on. The GetOptions Functions and [SETOPTIONS Procedures](#) work on individual SecureFiles. You can turn off a feature on a particular SecureFile and turn on a feature that has already been turned off by SetOptions, but you cannot turn on an option that has not been given to the SecureFile when the table was created.

## 102.9.31 INSTR Functions

This function returns the matching position of the *n*th occurrence of the pattern in the LOB, starting from the offset you specify.

### Syntax

```
DBMS_LOB.INSTR (
    lob_loc    IN    BLOB,
    pattern    IN    RAW,
    offset     IN    INTEGER := 1,
    nth        IN    INTEGER := 1)
RETURN INTEGER;

DBMS_LOB.INSTR (
    lob_loc    IN    CLOB          CHARACTER SET ANY_CS,
    pattern    IN    VARCHAR2     CHARACTER SET lob_loc%CHARSET,
    offset     IN    INTEGER := 1,
    nth        IN    INTEGER := 1)
RETURN INTEGER;

DBMS_LOB.INSTR (
    file_loc   IN    BFILE,
    pattern    IN    RAW,
    offset     IN    INTEGER := 1,
    nth        IN    INTEGER := 1)
RETURN INTEGER;
```

### Pragmas

```
pragma restrict_references(INSTR, WNDS, WNPS, RND, RNPS);
```

### Parameters

**Table 102-67 INSTR Function Parameters**

| Parameter | Description                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------|
| lob_loc   | Locator for the LOB to be examined. For more information, see <a href="#">Operational Notes</a> . |
| file_loc  | The file locator for the LOB to be examined.                                                      |

**Table 102-67 (Cont.) INSTR Function Parameters**

| Parameter | Description                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pattern   | Pattern to be tested for. The pattern is a group of RAW bytes for BLOBs, and a character string (VARCHAR2) for CLOBs. The maximum size of the pattern is 16383 bytes. |
| offset    | Absolute offset in bytes (BLOBs) or characters (CLOBs) at which the pattern matching is to start. (origin: 1)                                                         |
| nth       | Occurrence number, starting at 1.                                                                                                                                     |

### Return Values

**Table 102-68 INSTR Function Return Values**

| Return  | Description                                                                                                                                     |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| INTEGER | Offset of the start of the matched pattern, in bytes or characters. It returns 0 if the pattern is not found.                                   |
| NULL    | Either:<br>-any one or more of the IN parameters was NULL or INVALID.<br>-offset < 1 or offset > LOBMAXSIZE.<br>-nth < 1.<br>-nth > LOBMAXSIZE. |

### Usage Notes

The form of the VARCHAR2 buffer (the pattern parameter) must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

For BFILES, the file must be already opened using a successful FILEOPEN operation for this operation to succeed.

Operations that accept RAW or VARCHAR2 parameters for pattern matching, such as INSTR, do not support regular expressions or special matching characters (as in the case of SQL LIKE) in the pattern parameter or substrings.

### Exceptions

**Table 102-69 INSTR Function Exceptions for BFILES**

| Exception         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| UNOPENED_FILE     | File was not opened using the input locator.                           |
| NOEXIST_DIRECTORY | Directory does not exist.                                              |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.                          |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.              |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file. |

**Table 102-69 (Cont.) INSTR Function Exceptions for BFILES**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

**See Also:**

- ["SUBSTR Functions"](#)
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.32 ISOPEN Functions

This function checks to see if the LOB was already opened using the input locator. This subprogram is for internal and external LOBs.

### Syntax

```
DBMS_LOB.ISOPEN (
    lob_loc IN BLOB)
    RETURN INTEGER;

DBMS_LOB.ISOPEN (
    lob_loc IN CLOB CHARACTER SET ANY_CS)
    RETURN INTEGER;

DBMS_LOB.ISOPEN (
    file_loc IN BFILE)
    RETURN INTEGER;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(isopen, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-70 ISOPEN Function Parameters**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |
| file_loc  | File locator.                                                              |

### Return Values

The return value is 1 if the LOB is open, 0 otherwise.

### Usage Notes

For **BFILES**, openness is associated with the locator. If the input locator was never passed to **OPEN**, the **BFILE** is not considered to be opened by this locator. However, a different locator

may have opened the BFILE. More than one OPEN can be performed on the same BFILE using different locators.

For internal LOBs, openness is associated with the LOB, not with the locator. If locator1 opened the LOB, then locator2 also sees the LOB as open. For internal LOBs, ISOPEN requires a round-trip, because it checks the state on the server to see if the LOB is indeed open.

For external LOBs (BFILEs), ISOPEN also requires a round-trip, because that's where the state is kept.

 **See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.33 ISREMOTE Function

This function checks to see if the LOB is local to the database or if it belongs to a remote database.

### Syntax

```
DBMS_LOB.ISREMOTE (
    lob_loc IN BLOB)
    RETURN BOOLEAN;

DBMS_LOB.ISREMOTE (
    lob_loc IN CLOB CHARACTER SET ANY_CS)
    RETURN BOOLEAN;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(isremote, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-71 ISREMOTE Function Parameter**

| Parameter | Description          |
|-----------|----------------------|
| lob_loc   | Locator for the LOB. |

### Return Values

BOOLEAN: TRUE for remote LOBs obtained over a database link; FALSE for LOBs obtained from local database

 **See Also:**

- Distributed LOBs* chapter in *Database SecureFiles and Large Objects Developer's Guide* for more details on the usage of this procedure.

## 102.9.34 ISSECUREFILE Function

This function returns `TRUE` if the LOB locator passed to it is for a SecureFile LOB. It returns `FALSE` otherwise.

### Syntax

```
DBMS_LOB ISSECUREFILE(  
    lob_loc IN BLOB)  
RETURN BOOLEAN;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(issecurefile, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-72 ISSECUREFILE Function Parameter**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Return Values

This function returns `TRUE` if the LOB locator passed to it is for a SecureFile LOB. It returns `FALSE` otherwise.

## 102.9.35 ISTEMPORARY Functions

This function determines whether a LOB instance is temporary.

### Syntax

```
DBMS_LOB.ISTEMPORARY (  
    lob_loc IN BLOB)  
RETURN INTEGER;  
  
DBMS_LOB.ISTEMPORARY (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
RETURN INTEGER;
```

### Pragmas

```
PRAGMA RESTRICT_REFERENCES(istemporary, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 102-73 ISTEMPORARY Procedure Parameters**

| Parameter | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| lob_loc   | LOB locator. For more information, see <a href="#">Operational Notes</a> . |

### Return Values

The return value is 1 if the LOB is temporary and exists; 0 if the LOB is not temporary or does not exist; `NULL` if the given locator is `NULL`.

### Usage Notes

When you free a Temporary LOB with `FREETEMPORARY`, the LOB locator is not set to `NULL`. Consequently, `ISTEMPORARY` will return 0 for a locator that has been freed but not explicitly reset to `NULL`.

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.36 LOADBLOBFROMFILE Procedure

This procedure loads data from `BFILE` to internal `BLOB`. This achieves the same outcome as `LOADFROMFILE`, and returns the new offsets.

### Syntax

```
DBMS_LOB.LOADBLOBFROMFILE (  
    dest_lob    IN OUT NOCOPY BLOB,  
    src_bfile   IN          BFILE,  
    amount      IN          INTEGER,  
    dest_offset IN OUT      INTEGER,  
    src_offset  IN OUT      INTEGER);
```

### Parameters

**Table 102-74** LOADBLOBFROMFILE Procedure Parameters

| Parameter                | Description                                                                                                                                                                                                                                          |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dest_lob</code>    | <code>BLOB</code> locator of the target for the load.                                                                                                                                                                                                |
| <code>src_bfile</code>   | <code>BFILE</code> locator of the source for the load.                                                                                                                                                                                               |
| <code>amount</code>      | Number of bytes to load from the <code>BFILE</code> . You can also use <code>DBMS_LOB.LOBMAXSIZE</code> to load until the end of the <code>BFILE</code> .                                                                                            |
| <code>dest_offset</code> | (IN) Offset in bytes in the destination <code>BLOB</code> (origin: 1) for the start of the write. (OUT) New offset in bytes in the destination <code>BLOB</code> right after the end of this write, which is also where the next write should begin. |
| <code>src_offset</code>  | (IN) Offset in bytes in the source <code>BFILE</code> (origin: 1) for the start of the read. (OUT) Offset in bytes in the source <code>BFILE</code> right after the end of this read, which is also where the next read should begin.                |

### Usage Notes

- You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source `BFILE`. The `amount` and `src_offset`, because they refer to the `BFILE`, are in terms of bytes, and the `dest_offset` is in bytes for `BLOBs`.

- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB. If the offset is less than the current length of the destination LOB, then existing data is overwritten.
- There is an error if the input amount plus offset exceeds the length of the data in the BFILE (unless the amount specified is LOBMAXSIZE which you can specify to continue loading until the end of the BFILE is reached).
- It is not mandatory that you wrap the LOB operation inside the OPEN/CLOSE operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the OPEN/CLOSE, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- LOADFROMFILE gets the destination LOB prior to the load unless the load covers the entire LOB.

#### Constants and Defaults

There is no easy way to omit parameters. You must either declare a variable for IN/OUT parameter or provide a default value for the IN parameter. Here is a summary of the constants and the defaults that can be used.

**Table 102-75 Suggested Values of the Parameter**

| Parameter   | Default Value            | Description              |
|-------------|--------------------------|--------------------------|
| amount      | DBMS_LOB.LOBMAXSIZE (IN) | Load the entire file     |
| dest_offset | 1 (IN)                   | start from the beginning |
| src_offset  | 1 (IN)                   | start from the beginning |

#### Constants defined in DBMSLOB.SQL

```
lobmaxsize          CONSTANT INTEGER          := DBMS_LOB.LOBMAXSIZE;
```

#### Exceptions

**Table 102-76 LOADBLOBFROMFILE Procedure Exceptions**

| Exception         | Description                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VALUE_ERROR       | Any of the input parameters are NULL or INVALID.                                                                                                                                                                 |
| INVALID_ARGVAL    | Either: <ul style="list-style-type: none"> <li>- src_offset or dest_offset &lt; 1.</li> <li>- src_offset or dest_offset &gt; LOBMAXSIZE.</li> <li>- amount &lt; 1.</li> <li>- amount &gt; LOBMAXSIZE.</li> </ul> |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the BLOB                                                                                                                          |

**See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.37 LOADCLOBFROMFILE Procedure

This procedure loads data from a BFILE to an internal CLOB/NCLOB with necessary character set conversion and returns the new offsets.

### Syntax

```
DBMS_LOB.LOADCLOBFROMFILE (
    dest_lob      IN OUT NOCOPY   NOCOPY CLOB CHARACTER SET ANY_CS,
    src_bfile     IN              BFILE,
    amount        IN              INTEGER,
    dest_offset   IN OUT          INTEGER,
    src_offset    IN OUT          INTEGER,
    bfile_csid    IN              NUMBER,
    lang_context  IN OUT          INTEGER,
    warning       OUT             INTEGER);
```

### Parameters

**Table 102-77** LOADCLOBFROMFILE Procedure Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dest_lob     | CLOB/NCLOB locator of the target for the load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| src_bfile    | BFILE locator of the source for the load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| amount       | Number of bytes to load from the BFILE. Use DBMS_LOB.LOBMAXSIZE of load until the end of the BFILE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| dest_offset  | (IN) Offset in characters in the destination CLOB (origin: 1) for the start of the write. (OUT) The new offset in characters right after the end of this load, which is also where the next load should start. It always points to the beginning of the first complete character after the end of load. If the last character is not complete, offset goes back to the beginning of the partial character.                                                                                                                                                                                   |
| src_offset   | (IN) Offset in bytes in the source BFILE (origin: 1) for the start of the read. (OUT) Offset in bytes in the source BFILE right after the end of this read, which is also where the next read should begin.                                                                                                                                                                                                                                                                                                                                                                                  |
| bfile_csid   | Character set id of the source (BFILE) file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| lang_context | (IN) Language context, such as shift status, for the current load.<br>(OUT) The language context at the time when the current load stopped, and what the next load should be using if continuing loading from the same source. This information is returned to the user so that they can use it for the continuous load without losing or misinterpreting any source data. For the very first load or if do not care, simply use the default 0. The details of this language context is hidden from the user. One does not need to know what it is or what's in it in order to make the call |

**Table 102-77 (Cont.) LOADCLOBFROMFILE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| warning   | (OUT) Warning message. This indicates something abnormal happened during the loading. It may or may not be caused by the user's mistake. The loading is completed as required, and it's up to the user to check the warning message. Currently, the only possible warning is the inconvertible character. This happens when the character in the source cannot be properly converted to a character in destination, and the default replacement character (for example, '?') is used in place. The message is defined the constant value <code>DBMS_LOB.WARN_INCONVERTIBLE_CHAR</code> . |

**Usage Notes**

You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source `BFILE`. The `amount` and `src_offset`, because they refer to the `BFILE`, are in terms of bytes, and the `dest_offset` is in characters for `CLOBs`.

If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination `CLOB`. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

There is an error if the input amount plus offset exceeds the length of the data in the `BFILE` (unless the amount specified is `LOBMAXSIZE` which you can specify to continue loading until the end of the `BFILE` is reached).

Note the following requirements:

- The destination character set is always the same as the database character set in the case of `CLOB` and national character set in the case of `NCLOB`.
- `csid=0` indicates the default behavior that uses database `csid` for `CLOB` and national `csid` for `NCLOB` in the place of source `csid`. Conversion is still necessary if it is of varying width
- It is not mandatory that you wrap the LOB operation inside the `OPEN/CLOSE` operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the `OPEN/CLOSE`, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

The source `BFILE` can contain data in the Unicode character set. The Unicode standard defines many encoding schemes that provide mappings from Unicode characters to sequences of bytes. [Table 102-78](#) lists Unicode encodings schemes supported by this subprogram.

**Table 102-78 Supported Unicode Encoding Schemes**

| Encoding Scheme | Oracle Name | bfile_csid Value |
|-----------------|-------------|------------------|
| UTF-8           | AL32UTF8    | 873              |

**Table 102-78 (Cont.) Supported Unicode Encoding Schemes**

| Encoding Scheme | Oracle Name | bfile_csid Value |
|-----------------|-------------|------------------|
| UTF-16BE        | AL16UTF16   | 2000             |
| UTF-16LE        | AL16UTF16LE | 2002             |
| CESU-8          | UTF8        | 871              |
| UTF-EBCDIC      | UTFE        | 872              |
| UTF-16          | UTF16       | 1000             |

All three UTF-16 encoding schemes encode Unicode characters as 2-byte unsigned integers. Integers can be stored in big-endian or in little-endian byte order. The UTF-16BE encoding scheme defines big-endian data. The UTF-16LE scheme defines little-endian data. The UTF-16 scheme requires that the source BFILE contains the Byte Order Mark (BOM) character in the first two bytes to define the byte order. The BOM code is 0xFEFF. If the code is stored as {0xFE, 0xFF}, the data is interpreted as big-endian. If it is stored as {0xFF, 0xFE}, the data is interpreted as little-endian.

In UTF-8 and in CESU-8 encodings the Byte Order Mark is stored as {0xEF, 0xBB, 0xBF}. With any of the Unicode encodings, the corresponding BOM sequence at the beginning of the file is recognized and not loaded into the destination LOB.

### Constants

Here is a summary of the constants and the suggested values that can be used.

**Table 102-79 Suggested Values of the LOADCLOBFROMFILE Parameter**

| Parameter    | Suggested Value          | Description                          |
|--------------|--------------------------|--------------------------------------|
| amount       | DBMS_LOB.LOBMAXSIZE (IN) | Load the entire file                 |
| dest_offset  | 1 (IN)                   | start from the beginning             |
| src_offset   | 1 (IN)                   | start from the beginning             |
| csid         | 0 (IN)                   | default csid, use destination csid   |
| lang_context | 0 (IN)                   | default language context             |
| warning      | 0 (OUT)                  | no warning message, everything is ok |

Constants defined in DBMSLOB.SQL

## 102.9.38 LOADFROMFILE Procedure

This deprecated procedure copies all, or a part of, a source external LOB (BFILE) to a destination internal LOB.

**Note:**

This procedure has been deprecated starting in Oracle Database 12c release 12.2.

### Syntax

```
DBMS_LOB.LOADFROMFILE (
    dest_lob    IN OUT NOCOPY BLOB,
    src_file    IN          BFILE,
    amount      IN          INTEGER,
    dest_offset IN          INTEGER := 1,
    src_offset  IN          INTEGER := 1);
```

### Parameters

**Table 102-81 LOADFROMFILE Procedure Parameters**

| Parameter   | Description                                                                                 |
|-------------|---------------------------------------------------------------------------------------------|
| dest_lob    | LOB locator of the target for the load.                                                     |
| src_file    | BFILE locator of the source for the load.                                                   |
| amount      | Number of bytes to load from the BFILE.                                                     |
| dest_offset | Offset in bytes or characters in the destination LOB (origin: 1) for the start of the load. |
| src_offset  | Offset in bytes in the source BFILE (origin: 1) for the start of the load.                  |

## Usage Notes

You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The `amount` and `src_offset`, because they refer to the BFILE, are in terms of bytes, and the `dest_offset` is either in bytes or characters for BLOBs and CLOBs respectively.

### Note:

The input BFILE must have been opened prior to using this procedure. No character set conversions are performed implicitly when binary BFILE data is loaded into a CLOB. The BFILE data must already be in the same character set as the CLOB in the database. No error checking is performed to verify this.

If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

There is an error if the input amount plus offset exceeds the length of the data in the BFILE.

### Note:

If the character set is varying width, UTF-8 for example, the LOB value is stored in the fixed-width UCS2 format. Therefore, if you are using `DBMS_LOB.LOADFROMFILE`, the data in the BFILE should be in the UCS2 character set instead of the UTF-8 character set. However, you should use `sql*loader` instead of `LOADFROMFILE` to load data into a CLOB or NCLOB because `sql*loader` provides the necessary character set conversions.

It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

## Exceptions

**Table 102-82 LOADFROMFILE Procedure Exceptions**

| Exception   | Description                                      |
|-------------|--------------------------------------------------|
| VALUE_ERROR | Any of the input parameters are NULL or INVALID. |

**Table 102-82 (Cont.) LOADFROMFILE Procedure Exceptions**

| Exception      | Description                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| INVALID_ARGVAL | Either:<br>- src_offset or dest_offset < 1.<br>- src_offset or dest_offset > LOBMAXSIZE.<br>- amount < 1.<br>- amount > LOBMAXSIZE. |

## 102.9.39 MOVE\_TO\_DBFS\_LINK Procedures

This procedure archives the specified LOB data (from the database) into the DBFS HSM Store.

### Syntax

```
DBMS_LOB.MOVE_TO_DBFS_LINK (
  lob_loc      IN OUT BLOB,
  storage_path IN      VARCHAR2(dbfs_link_path_max_size),
  flags        IN      BINARY_INTEGER DEFAULT DBFS_LINK_NOCACHE);

DBMS_LOB.MOVE_TO_DBFS_LINK (
  lob_loc      IN OUT CLOB CHARACTER SET ANY_CS,
  storage_path IN      VARCHAR2(dbfs_link_path_max_size),
  flags        IN      BINARY_INTEGER DEFAULT DBFS_LINK_NOCACHE);
```

### Parameters

**Table 102-83 MOVE\_TO\_DBFS\_LINK Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lob_loc      | LOB to be archived                                                                                                                                                                                                                                                                  |
| storage_path | Path where the LOB will be stored                                                                                                                                                                                                                                                   |
| flags        | Either DBFS_LINK_CACHE or DBFS_LINK_NOCACHE. If DBFS_LINK_CACHE is specified, the LOB data continues to be stored in the RDBMS as well as being written to the DBFS store. DBFS_LINK_NOCACHE specifies that the LOB data should be deleted from the RDBMS once written to the DBFS. |

### Exceptions

**Table 102-84 MOVE\_TO\_DBFS\_LINK Procedure Exceptions**

| Exception         | Description                 |
|-------------------|-----------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE |

### Usage Notes

- If the LOB is already archived, the procedure silently returns as if the put was successful. In that case, if `DBFS_LINK_NOCACHE` is specified, or `flags` is defaulted, the LOB data is removed from the RDBMS.
- Calling this procedure multiple times on the same LOB with the same flags has no effect.
- Calling the procedure on a LOB that is already archived causes the LOB to be cached (`DBFS_LINK_CACHE`) or removed (`DBFS_LINK_NOCACHE`) according to the flag setting.

## 102.9.40 OPEN Procedures

This procedure opens a LOB, internal or external, in the indicated mode. Valid modes include read-only, and read/write.

### Syntax

```
DBMS_LOB.OPEN (
    lob_loc    IN OUT NOCOPY BLOB,
    open_mode  IN             BINARY_INTEGER);

DBMS_LOB.OPEN (
    lob_loc    IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    open_mode  IN             BINARY_INTEGER);

DBMS_LOB.OPEN (
    file_loc   IN OUT NOCOPY BFILE,
    open_mode  IN             BINARY_INTEGER := file_readonly);
```

### Parameters

**Table 102-85 OPEN Procedure Parameters**

| Parameter              | Description                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lob_loc</code>   | LOB locator. For more information, see <a href="#">Operational Notes</a> .                                                                                                                             |
| <code>open_mode</code> | Mode in which to open.<br>For BLOB and CLOB types, the mode can be either: <code>LOB_READONLY</code> or <code>LOB_READWRITE</code> .<br>For BFILE types, the mode must be <code>FILE_READONLY</code> . |

### Usage Notes

#### Note:

If the LOB was opened in read-only mode, and if you try to write to the LOB, then an error is returned. `BFILE` can only be opened with read-only mode.

`OPEN` requires a round-trip to the server for both internal and external LOBs. For internal LOBs, `OPEN` triggers other code that relies on the `OPEN` call. For external LOBs (`BFILES`), `OPEN` requires a round-trip because the actual operating system file on the server side is being opened.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.

**See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.41 READ Procedures

This procedure reads a piece of a LOB, and returns the specified amount into the `buffer` parameter, starting from an absolute offset from the beginning of the LOB.

The number of bytes or characters actually read is returned in the `amount` parameter. If the input `offset` points past the End of LOB, then `amount` is set to 0, and a `NO_DATA_FOUND` exception is raised.

### Syntax

```
DBMS_LOB.READ (
  lob_loc   IN          BLOB,
  amount    IN OUT      NOCOPY INTEGER,
  offset     IN          INTEGER,
  buffer     OUT         RAW);

DBMS_LOB.READ (
  lob_loc   IN          CLOB CHARACTER SET ANY_CS,
  amount    IN OUT      NOCOPY INTEGER,
  offset     IN          INTEGER,
  buffer     OUT         VARCHAR2 CHARACTER SET lob_loc%CHARSET);

DBMS_LOB.READ (
  file_loc  IN          BFILE,
  amount    IN OUT      NOCOPY INTEGER,
  offset     IN          INTEGER,
  buffer     OUT         RAW);
```

### Parameters

**Table 102-86** READ Procedure Parameters

| Parameter             | Description                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------|
| <code>lob_loc</code>  | Locator for the LOB to be read. For more information, see <a href="#">Operational Notes</a> . |
| <code>file_loc</code> | The file locator for the LOB to be examined.                                                  |

**Table 102-86 (Cont.) READ Procedure Parameters**

| Parameter | Description                                                                                  |
|-----------|----------------------------------------------------------------------------------------------|
| amount    | Number of bytes (for BLOBs) or characters (for CLOBs) to read, or number that were read.     |
| offset    | Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1). |
| buffer    | Output buffer for the read operation.                                                        |

### Exceptions

[Table 102-87](#) lists exceptions that apply to any LOB instance. [Table 102-88](#) lists exceptions that apply only to BFILES.

**Table 102-87 READ Procedure Exceptions**

| Exception      | Description                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VALUE_ERROR    | Any of lob_loc, amount, or offset parameters are NULL.                                                                                                                                                                                                                             |
| INVALID_ARGVAL | Either: <ul style="list-style-type: none"><li>- amount &lt; 1</li><li>- amount &gt; 32767 bytes (or the character equivalent)</li><li>- offset &lt; 1</li><li>- offset &gt; LOBMAXSIZE</li><li>- amount is greater, in bytes or characters, than the capacity of buffer.</li></ul> |
| NO_DATA_FOUND  | End of the LOB is reached, and there are no more bytes or characters to read from the LOB: amount has a value of 0.                                                                                                                                                                |

**Table 102-88 READ Procedure Exceptions for BFILES**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| UNOPENED_FILE     | File is not opened using the input locator.                                            |
| NOEXIST_DIRECTORY | Directory does not exist.                                                              |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.                                          |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.                              |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file.                 |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

### Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
- When calling DBMS\_LOB.READ from the client (for example, in a BEGIN/END block from within SQL\*Plus), the returned buffer contains data in the client's character set. The database

converts the LOB value from the server's character set to the client's character set before it returns the buffer to the user.

- READ gets the LOB, if necessary, before the read.
- If the LOB is a DBFS LINK, data is streamed from DBFS, if possible, otherwise an exception is thrown.

## 102.9.42 SET\_DBFS\_LINK Procedures

This function links the specified SecureFile to the specified path name. It does not copy the data to the path.

### Syntax

```
DBMS_LOB.SET_DBFS_LINK (
    lob_loc          IN OUT BLOB,
    archive_id       IN      RAW(1024));

DBMS_LOB.SET_DBFS_LINK(
    lob_loc_dst      IN OUT CLOB CHARACTER SET ANY_CS,
    archive_id       IN      RAW(1024));
```

### Parameters

**Table 102-89 SET\_DBFS\_LINK Procedure Parameters**

| Parameter  | Description                                                                             |
|------------|-----------------------------------------------------------------------------------------|
| lob_loc    | LOB for which to store the reference value                                              |
| archive_id | Archive ID as returned by calling either of the <a href="#">GET_DBFS_LINK Functions</a> |

### Exceptions

**Table 102-90 SET\_DBFS\_LINK Procedure Exceptions**

| Exception         | Description                 |
|-------------------|-----------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE |

## 102.9.43 SETCONTENTTYPE Procedure

This procedure sets the content type string for the data in the LOB.

### Syntax

```
DBMS_LOB.SETCONTENTTYPE (
    lob_loc          IN OUT NOCOPY BLOB,
```

```

        contenttype IN          VARCHAR2);

DBMS_LOB.SETCONTENTTYPE (
    lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    contenttype IN          VARCHAR2);

```

### Parameters

**Table 102-91 SETCONTENTTYPE Procedure Parameters**

| Parameter   | Description                         |
|-------------|-------------------------------------|
| lob_loc     | LOB to be assigned the content type |
| contenttype | String to be assigned               |

### Exceptions

**Table 102-92 SETCONTENTTYPE Procedure Exceptions**

| Exception         | Description                 |
|-------------------|-----------------------------|
| SECUREFILE_BADLOB | lob_loc is not a SECUREFILE |

### Usage Notes

To clear an existing content type associated with a SECUREFILE, invoke SETCONTENTTYPE with contenttype set to empty string.

## 102.9.44 SETOPTIONS Procedures

This procedure enables/disables compression and deduplication on a per-LOB basis, overriding the default LOB column settings.

### Syntax

```

DBMS_LOB.SETOPTIONS (
    lob_loc      IN      BLOB,
    option_types IN      PLS_INTEGER,
    options      IN      PLS_INTEGER);

DBMS_LOB.SETOPTIONS (
    lob_loc      IN      CLOB CHARACTER SET ANY_CS,
    option_types IN      PLS_INTEGER,
    options      IN      PLS_INTEGER);

```

### Parameters

**Table 102-93 SETOPTIONS Procedure Parameter**

| Parameter   | Description                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------|
| lob_loc     | Locator for the LOB to be examined. For more information, see <a href="#">Operational Notes</a> . |
| option_type | See <a href="#">Table 102-2</a>                                                                   |
| options     | See <a href="#">Table 102-3</a>                                                                   |

## Exceptions

**Table 102-94** SETOPTIONS Procedure Exceptions

| Exception         | Description                                         |
|-------------------|-----------------------------------------------------|
| SECUREFILE_BADLOB | Unsupported object type for the operation           |
| INVALID_ARGVAL    | A parameter value was invalid                       |
| QUERY_WRITE       | Cannot perform operation during a query             |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled |

## Usage Notes

- DBMS\_LOB.SETOPTIONS cannot be used to enable or disable encryption on individual LOBs.
- You cannot turn the compression or deduplication features on or off for a SecureFile column if they were not turned when the table was created.  
  
The [GETOPTIONS Functions](#) and SETOPTIONS Procedures work on individual SecureFiles. You can turn off compression or deduplication on a particular SecureFiles LOB and turn on them on, *if* they have already been turned off by SETOPTIONS.
- This call incurs a round-trip to the server to make the changes persistent.

## 102.9.45 SUBSTR Functions

This function returns `amount` bytes or characters of a LOB, starting from an absolute `offset` from the beginning of the LOB.

For fixed-width `n`-byte CLOBs, if the input `amount` for SUBSTR is greater than  $(32767/n)$ , then SUBSTR returns a character buffer of length  $(32767/n)$ , or the length of the CLOB, whichever is lesser. For CLOBs in a varying-width character set, `n` is the maximum byte-width used for characters in the CLOB.

## Syntax

```
DBMS_LOB.SUBSTR (
    lob_loc      IN      BLOB,
    amount       IN      INTEGER := 32767,
    offset       IN      INTEGER := 1)
RETURN RAW;

DBMS_LOB.SUBSTR (
    lob_loc      IN      CLOB CHARACTER SET ANY_CS,
    amount       IN      INTEGER := 32767,
    offset       IN      INTEGER := 1)
RETURN VARCHAR2 CHARACTER SET lob_loc%CHARSET;

DBMS_LOB.SUBSTR (
    file_loc     IN      BFILE,
    amount       IN      INTEGER := 32767,
    offset       IN      INTEGER := 1)
RETURN RAW;
```

## Pragmas

```
pragma restrict_references(SUBSTR, WNDS, WNPS, RNDS, RNPS);
```

## Parameters

**Table 102-95 SUBSTR Function Parameters**

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| lob_loc   | Locator for the LOB to be read. For more information, see <a href="#">Operational Notes</a> . |
| file_loc  | The file locator for the LOB to be examined.                                                  |
| amount    | Number of bytes (for BLOBs) or characters (for CLOBs) to be read.                             |
| offset    | Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1).  |

## Return Values

**Table 102-96 SUBSTR Function Return Values**

| Return   | Description                                                                                                                                                                                        |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RAW      | Function overloading that has a BLOB or BFILE in parameter.                                                                                                                                        |
| VARCHAR2 | CLOB version.                                                                                                                                                                                      |
| NULL     | Either: <ul style="list-style-type: none"><li>- any input parameter is NULL</li><li>- amount &lt; 1</li><li>- amount &gt; 32767</li><li>- offset &lt; 1</li><li>- offset &gt; LOBMAXSIZE</li></ul> |

## Exceptions

**Table 102-97 SUBSTR Function Exceptions for BFILE operations**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| UNOPENED_FILE     | File is not opened using the input locator.                                            |
| NOEXIST_DIRECTORY | Directory does not exist.                                                              |
| NOPRIV_DIRECTORY  | You do not have privileges for the directory.                                          |
| INVALID_DIRECTORY | Directory has been invalidated after the file was opened.                              |
| INVALID_OPERATION | File does not exist, or you do not have access privileges on the file.                 |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

## Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
- When calling DBMS\_LOB.SUBSTR from the client (for example, in a BEGIN/END block from within SQL\*Plus), the returned buffer contains data in the client's character set. The

database converts the LOB value from the server's character set to the client's character set before it returns the buffer to the user.

- `DBMS_LOB.SUBSTR` will return 8191 or more characters based on the characters stored in the LOBs. If all characters are not returned as a consequence of the character byte size exceeding the available buffer, the user should either call `DBMS_LOB.SUBSTR` with a new offset to read the remaining characters, or call the subprogram on loop until all the data is extracted.
- `SUBSTR` gets the LOB, if necessary, before read.
- If the LOB is a DBFS Link, the data is streamed from DBFS, if possible, otherwise, an exception is thrown.

- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

## 102.9.46 TRIM Procedures

This procedure trims the value of the internal LOB to the length you specify in the `newlen` parameter.

Specify the length in bytes for `BLOBs`, and specify the length in characters for `CLOBs`.

#### Note:

The `TRIM` procedure decreases the length of the LOB to the value specified in the `newlen` parameter.

If you attempt to `TRIM` an empty LOB, then nothing occurs, and `TRIM` returns no error. If the new length that you specify in `newlen` is greater than the size of the LOB, then an exception is raised.

#### Syntax

```
DBMS_LOB.TRIM (
  lob_loc      IN OUT NOCOPY BLOB,
  newlen       IN          INTEGER) ;

DBMS_LOB.TRIM (
  lob_loc      IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
  newlen       IN          INTEGER) ;
```

## Parameters

**Table 102-98 TRIM Procedure Parameters**

| Parameter | Description                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| lob_loc   | Locator for the internal LOB whose length is to be trimmed. For more information, see <a href="#">Operational Notes</a> . |
| newlen    | New, trimmed length of the LOB value in bytes for BLOBs or characters for CLOBs.                                          |

## Exceptions

**Table 102-99 TRIM Procedure Exceptions**

| Exception         | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| VALUE_ERROR       | lob_loc is NULL.                                                                       |
| INVALID_ARGVAL    | Either:<br>- new_len < 0<br>- new_len > LOBMAXSIZE                                     |
| QUERY_WRITE       | Cannot perform a LOB write inside a query or PDML parallel execution server            |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

## Usage Notes

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.
- `TRIM` gets the LOB, if necessary, before altering the length of the LOB, unless the new length specified is '0'

## 102.9.47 WRITE Procedures

This procedure writes a specified amount of data into an internal LOB, starting from an absolute offset from the beginning of the LOB. The data is written from the `buffer` parameter.

`WRITE` replaces (overwrites) any data that already exists in the LOB at the offset, for the length you specify.

### Syntax

```
DBMS_LOB.WRITE (
    lob_loc  IN OUT NOCOPY BLOB,
    amount   IN             INTEGER,
    offset   IN             INTEGER,
    buffer   IN             RAW);

DBMS_LOB.WRITE (
    lob_loc  IN OUT NOCOPY CLOB  CHARACTER SET ANY_CS,
    amount   IN             INTEGER,
    offset   IN             INTEGER,
    buffer   IN             VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

### Parameters

**Table 102-100** WRITE Procedure Parameters

| Parameter            | Description                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>lob_loc</code> | Locator for the internal LOB to be written to. For more information, see <a href="#">Operational Notes</a>           |
| <code>amount</code>  | Number of bytes (for BLOBs) or characters (for CLOBs) to write                                                       |
| <code>offset</code>  | Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1) for the write operation. |
| <code>buffer</code>  | Input buffer for the write                                                                                           |

### Exceptions

**Table 102-101** WRITE Procedure Exceptions

| Exception                      | Description                                                                                                                                                                                                                                          |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VALUE_ERROR</code>       | Any of <code>lob_loc</code> , <code>amount</code> , or <code>offset</code> parameters are <code>NULL</code> , out of range, or <code>INVALID</code> .                                                                                                |
| <code>INVALID_ARGVAL</code>    | Either: <ul style="list-style-type: none"><li>- <code>amount &lt; 1</code></li><li>- <code>amount &gt; 32767</code> bytes (or the character equivalent)</li><li>- <code>offset &lt; 1</code></li><li>- <code>offset &gt; LOBMAXSIZE</code></li></ul> |
| <code>QUERY_WRITE</code>       | Cannot perform a LOB write inside a query or PDML parallel execution server                                                                                                                                                                          |
| <code>BUFFERING_ENABLED</code> | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB                                                                                                                                                               |

Table 102-101 (Cont.) WRITE Procedure Exceptions

| Exception              | Description                                                                          |
|------------------------|--------------------------------------------------------------------------------------|
| SECUREFILE_OUTOFBOUNDS | Attempted to perform a write operation past the end of a LOB having FRAGMENT_* on it |

### Usage Notes

- There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer is written to the LOB. If the offset you specify is beyond the end of the data currently in the LOB, then zero-byte fillers or spaces are inserted in the BLOB or CLOB respectively.
- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
- When calling DBMS\_LOB.WRITE from the client (for example, in a BEGIN/END block from within SQL\*Plus), the buffer must contain data in the client's character set. The database converts the client-side buffer to the server's character set before it writes the buffer data to the LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- WRITE gets the LOB, if necessary, before writing the LOB, unless the write is specified to overwrite the entire LOB.

## 102.9.48 WRITEAPPEND Procedures

This procedure writes a specified amount of data to the end of an internal LOB. The data is written from the `buffer` parameter.

### Syntax

```
DBMS_LOB.WRITEAPPEND (
    lob_loc IN OUT NOCOPY BLOB,
    amount  IN              INTEGER,
    buffer  IN              RAW);

DBMS_LOB.WRITEAPPEND (
    lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    amount  IN              INTEGER,
    buffer  IN              VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

### Parameters

**Table 102-102** WRITEAPPEND Procedure Parameters

| Parameter            | Description                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------|
| <code>lob_loc</code> | Locator for the internal LOB to be written to. For more information, see <a href="#">Operational Notes</a> |
| <code>amount</code>  | Number of bytes (for BLOBs) or characters (for CLOBs) to write                                             |
| <code>buffer</code>  | Input buffer for the write                                                                                 |

### Usage Notes

There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer are written to the end of the LOB.

### Exceptions

**Table 102-103** WRITEAPPEND Procedure Exceptions

| Exception                      | Description                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>VALUE_ERROR</code>       | Any of <code>lob_loc</code> , <code>amount</code> , or <code>offset</code> parameters are NULL, out of range, or INVALID. |
| <code>INVALID_ARGVAL</code>    | Either:<br>- <code>amount &lt; 1</code><br>- <code>amount &gt; 32767</code> bytes (or the character equivalent)           |
| <code>QUERY_WRITE</code>       | Cannot perform a LOB write inside a query or PDML parallel execution server                                               |
| <code>BUFFERING_ENABLED</code> | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB                                    |

### Usage Notes

- The form of the `VARCHAR2` buffer must match the form of the `CLOB` parameter. In other words, if the input LOB parameter is of type `NCLOB`, then the buffer must contain `NCHAR`

data. Conversely, if the input LOB parameter is of type `CLOB`, then the buffer must contain `CHAR` data.

- When calling `DBMS_LOB.WRITEAPPEND` from the client (for example, in a `BEGIN/END` block from within `SQL*Plus`), the buffer must contain data in the client's character set. The database converts the client-side buffer to the server's character set before it writes the buffer data to the LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.
- `WRITEAPPEND` gets the LOB, if necessary, before appending to the LOB.

# DBMS\_LOCK

The `DBMS_LOCK` package provides an interface to Oracle Lock Management services.

You can request a lock of a specific mode, give it a unique name recognizable in another procedure in the same or another instance, change the lock mode, and release it.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Rules and Limits](#)
- [Operational Notes](#)
- [Summary of DBMS\\_LOCK Subprograms](#)

## See Also:

For more information, and an example of how to use the `DBMS_LOCK` package, *Oracle Database Development Guide*

## 103.1 DBMS\_LOCK Overview

The `DBMS_LOCK` package has many beneficial uses.

These uses include the following:

- Providing exclusive access to a device, such as a terminal
- Providing application-level enforcement of read locks
- Detecting when a lock is released and cleanup after the application
- Synchronizing applications and enforcing sequential processing

## 103.2 DBMS\_LOCK Security Model

There might be operating system-specific limits on the maximum number of total locks available. This *must* be considered when using locks or making this package available to other users. Consider granting the `EXECUTE` privilege only to specific users or roles.

A better alternative would be to create a cover package limiting the number of locks used and grant `EXECUTE` privilege to specific users. An example of a cover package is documented in the `DBMS_LOCK.SQL` package specification file. The abbreviations for these locks as they appear in Enterprise Manager monitors are in parentheses.

## 103.3 DBMS\_LOCK Constants

The DBMS\_LOCK package includes several constants to use when specifying parameter values.

These constants are shown in the following table.

**Table 103-1 DBMS\_LOCK Constants**

| Name     | Alternate Name(s)                                                                                                | Type    | Value | OEM Abbreviation | Description                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------|---------|-------|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| NL_MODE  | NuLl                                                                                                             | INTEGER | 1     | -                | -                                                                                                                                  |
| SS_MODE  | Sub Shared                                                                                                       | INTEGER | 2     | ULRS             | This can be used on an aggregate object to indicate that share locks are being acquired on subparts of the object.                 |
| SX_MODE  | <ul style="list-style-type: none"> <li>Sub eXclusive</li> <li>Row Exclusive Mode</li> </ul>                      | INTEGER | 3     | ULRX             | This can be used on an aggregate object to indicate that exclusive locks are being acquired on sub-parts of the object.            |
| S_MODE   | <ul style="list-style-type: none"> <li>Shared</li> <li>Row Exclusive Mode</li> <li>Intended Exclusive</li> </ul> | INTEGER | 4     | ULRSX            | -                                                                                                                                  |
| SSX_MODE | <ul style="list-style-type: none"> <li>Shared Sub eXclusive</li> <li>Share Row Exclusive Mode</li> </ul>         | INTEGER | 5     | -                | This indicates that the entire aggregate object has a share lock, but some of the sub-parts may additionally have exclusive locks. |
| X_MODE   | Exclusive                                                                                                        | INTEGER | 6     | ULX              | -                                                                                                                                  |

These are the various lock modes (nl -> "NuLl", ss -> "Sub Shared", sx -> "Sub eXclusive", s -> "Shared", ssx -> "Shared Sub eXclusive", x -> "eXclusive").

## 103.4 DBMS\_LOCK. Rules and Limits

When another process holds "held", an attempt to get "get" succeeds or fails, based on the held mode and type of get.

The following table describes the results:

**Table 103-2 Lock Compatibility**

| HELD MODE | GET NL  | GET SS  | GET SX  | GET S   | GET SSX | GET X   |
|-----------|---------|---------|---------|---------|---------|---------|
| NL        | Success | Success | Success | Success | Success | Success |
| SS        | Success | Success | Success | Success | Success | Fail    |
| SX        | Success | Success | Success | Fail    | Fail    | Fail    |
| S         | Success | Success | Fail    | Success | Fail    | Fail    |
| SSX       | Success | Success | Fail    | Fail    | Fail    | Fail    |
| X         | Success | Fail    | Fail    | Fail    | Fail    | Fail    |

```
maxwait constant integer := 32767;
```

The constant `maxwait` waits forever.

## 103.5 DBMS\_LOCK Operational Notes

User locks never conflict with Oracle locks because they are identified with the prefix "UL". You can view these locks using the Enterprise Manager lock monitor screen or the appropriate fixed views.

User locks are automatically released when a session terminates. The lock identifier is a number in the range of 0 to 1073741823.

Because a reserved user lock is the same as an Oracle lock, it has all the functionality of an Oracle lock, such as deadlock detection. Be certain that any user locks used in distributed transactions are released upon `COMMIT`, or an undetected deadlock may occur.

`DBMS_LOCK` is most efficient with a limit of a few hundred locks for each session. Oracle strongly recommends that you develop a standard convention for using these locks in order to avoid conflicts among procedures trying to use the same locks. For example, include your company name as part of your lock names.

## 103.6 Summary of DBMS\_LOCK Subprograms

This table lists the `DBMS_LOCK` subprograms and briefly describes them.

**Table 103-3** *DBMS\_LOCK Package Subprograms*

| Subprogram                                           | Description                                |
|------------------------------------------------------|--------------------------------------------|
| <a href="#">ALLOCATE_UNIQUE Procedure</a>            | Allocates a unique lock ID to a named lock |
| <a href="#">ALLOCATE_UNIQUE_AUTONOMOUS Procedure</a> | Allocates a unique lock ID to a named lock |
| <a href="#">CONVERT Function</a>                     | Converts a lock from one mode to another   |
| <a href="#">RELEASE Function</a>                     | Releases a lock                            |

### 103.6.1 ALLOCATE\_UNIQUE Procedure

This procedure allocates a unique lock identifier (in the range of 1073741824 to 1999999999) a specified lock name. Lock identifiers are used to enable applications to coordinate their use of locks. This is provided because it may be easier for applications to coordinate their use of locks based on lock names rather than lock numbers.

#### Syntax

```
DBMS_LOCK.ALLOCATE_UNIQUE (  
    lockname          IN  VARCHAR2,  
    lockhandle        OUT VARCHAR2,  
    expiration_secs   IN  INTEGER  DEFAULT 864000);
```

## Parameters

**Table 103-4** ALLOCATE\_UNIQUE Procedure Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lockname        | Name of the lock for which you want to generate a unique ID.<br>Do not use lock names beginning with ORA\$; these are reserved for products supplied by Oracle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| lockhandle      | Returns the handle to the lock ID generated by ALLOCATE_UNIQUE.<br>You can use this handle in subsequent calls to REQUEST, CONVERT, and RELEASE.<br><br>A handle is returned instead of the actual lock ID to reduce the chance that a programming error accidentally creates an incorrect, but valid, lock ID. This provides better isolation between different applications that are using this package.<br><br>LOCKHANDLE can be up to VARCHAR2 (128).<br><br>All sessions using a lock handle returned by ALLOCATE_UNIQUE with the same lock name are referring to the same lock. Therefore, do not pass lock handles from one session to another. |
| expiration_secs | Number of seconds to wait after the last ALLOCATE_UNIQUE has been performed on a specified lock, before permitting that lock to be deleted from the DBMS_LOCK_ALLOCATED table.<br><br>The default waiting period is 10 days. You should not delete locks from this table. Subsequent calls to ALLOCATE_UNIQUE may delete expired locks to recover space.                                                                                                                                                                                                                                                                                               |

## Usage Notes

If you choose to identify locks by name, you can use ALLOCATE\_UNIQUE to generate a unique lock identification number for these named locks.

The first session to call ALLOCATE\_UNIQUE with a new lock name causes a unique lock ID to be generated and stored in the dbms\_lock\_allocated table. Subsequent calls (usually by other sessions) return the lock ID previously generated.

A lock name is associated with the returned lock ID for at least expiration\_secs (defaults to 10 days) past the last call to ALLOCATE\_UNIQUE with the specified lock name. After this time, the row in the dbms\_lock\_allocated table for this lock name may be deleted in order to recover space. ALLOCATE\_UNIQUE performs a commit.

### WARNING:

Named user locks may be less efficient, because Oracle uses SQL to determine the lock associated with a specified name.

## Exceptions

ORA-20000, ORU-10003: Unable to find or insert lock <lockname> into catalog dbms\_lock\_allocated.

# 103.6.2 ALLOCATE\_UNIQUE\_AUTONOMOUS Procedure

This procedure allocates a unique lock identifier (in the range of 1073741824 to 1999999999) a specified lock name and is an autonomous version of the `ALLOCATE_UNIQUE` procedure. This procedure works exactly same as that of `ALLOCATE_UNIQUE`, except that the procedure will run as an autonomous transaction. Therefore the commits in `ALLOCATE_UNIQUE_AUTONOMOUS` procedure will not affect the calling procedure. The `ALLOCATE_UNIQUE_AUTONOMOUS` procedure is implemented in DB 12.1 and later releases.

## Syntax

```
DBMS_LOCK.ALLOCATE_UNIQUE_AUTONOMOUS (  
    lockname      IN  VARCHAR2,  
    lockhandle    OUT VARCHAR2,  
    expiration_secs IN  INTEGER  DEFAULT 864000);
```

## Parameters

**Table 103-5    ALLOCATE\_UNIQUE\_AUTONOMOUS Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lockname        | Name of the lock for which you want to generate a unique ID.<br><br>Do not use lock names beginning with <code>ORA\$</code> ; these are reserved for products supplied by Oracle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| lockhandle      | Returns the handle to the lock ID generated by <code>ALLOCATE_UNIQUE_AUTONOMOUS</code> .<br><br>You can use this handle in subsequent calls to <code>REQUEST</code> , <code>CONVERT</code> , and <code>RELEASE</code> .<br><br>A handle is returned instead of the actual lock ID to reduce the chance that a programming error accidentally creates an incorrect, but valid, lock ID. You should not delete locks from this table. Subsequent calls to <code>ALLOCATE_UNIQUE_AUTONOMOUS</code> may delete expired locks to recover space.                                                                                                                                                                                                                                                                                                                                                     |

## Usage Notes

If you choose to identify locks by name, you can use `ALLOCATE_UNIQUE_AUTONOMOUS` to generate a unique lock identification number for these named locks.

The first session to call `ALLOCATE_UNIQUE_AUTONOMOUS` with a new lock name causes a unique lock ID to be generated and stored in the `dbms_lock_allocated` table. Subsequent calls (usually by other sessions) return the lock ID previously generated.

A lock name is associated with the returned lock ID for at least `expiration_secs` (defaults to 10 days) past the last call to `ALLOCATE_UNIQUE_AUTONOMOUS` with the specified lock name. After this time, the row in the `dbms_lock_allocated` table for this lock name may be deleted in order to recover space. `ALLOCATE_UNIQUE_AUTONOMOUS` performs a commit.

**WARNING:**

Named user locks may be less efficient, because Oracle uses SQL to determine the lock associated with a specified name.

**Exceptions**

ORA-20000, ORU-10003: Unable to find or insert lock <lockname> into catalog  
`dbms_lock_allocated`.

### 103.6.3 CONVERT Function

This function converts a lock from one mode to another. `CONVERT` is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the `ALLOCATE_UNIQUE` procedure.

**Syntax**

```
DBMS_LOCK.CONVERT(  
    id          IN INTEGER ||  
    lockhandle  IN VARCHAR2,  
    lockmode    IN INTEGER,  
    timeout     IN NUMBER DEFAULT MAXWAIT)  
RETURN INTEGER;
```

**Parameters**

**Table 103-6** CONVERT Function Parameters

| Parameter        | Description                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id or lockhandle | User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by <code>ALLOCATE_UNIQUE</code> , of the lock mode you want to change                 |
| lockmode         | New mode that you want to assign to the specified lock.<br>For the available modes and their associated integer identifiers, see <a href="#">Constants</a> .            |
| timeout          | Number of seconds to continue trying to change the lock mode.<br>If the lock cannot be converted within this time period, then the call returns a value of 1 (timeout). |

**Return Values**

**Table 103-7** CONVERT Function Return Values

| Return Value | Description |
|--------------|-------------|
| 0            | Success     |

**Table 103-7 (Cont.) CONVERT Function Return Values**

| Return Value | Description                                                            |
|--------------|------------------------------------------------------------------------|
| 1            | Timeout                                                                |
| 2            | Deadlock                                                               |
| 3            | Parameter error                                                        |
| 4            | Don't own lock specified by <code>id</code> or <code>lockhandle</code> |
| 5            | Illegal lock handle                                                    |

## 103.6.4 RELEASE Function

This function explicitly releases a lock previously acquired using the `REQUEST` function.

Locks are automatically released at the end of a session. `RELEASE` is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the `ALLOCATE_UNIQUE` procedure.

### Syntax

```
DBMS_LOCK.RELEASE (  
    id          IN INTEGER)  
    RETURN INTEGER;
```

```
DBMS_LOCK.RELEASE (  
    lockhandle IN VARCHAR2)  
    RETURN INTEGER;
```

### Parameters

**Table 103-8 RELEASE Function Parameter**

| Parameter                                  | Description                                                                                                                                             |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code> or <code>lockhandle</code> | User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by <code>ALLOCATE_UNIQUE</code> , of the lock mode you want to change |

### Return Values

**Table 103-9 RELEASE Function Return Values**

| Return Value | Description                                                             |
|--------------|-------------------------------------------------------------------------|
| 0            | Success                                                                 |
| 3            | Parameter error                                                         |
| 4            | Do not own lock specified by <code>id</code> or <code>lockhandle</code> |
| 5            | Illegal lock handle                                                     |

## 103.6.5 REQUEST Function

This function requests a lock with a specified mode.

REQUEST is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the ALLOCATE\_UNIQUE procedure.

### Syntax

```
DBMS_LOCK.REQUEST(  
    id                IN  INTEGER ||  
    lockhandle        IN  VARCHAR2,  
    lockmode          IN  INTEGER DEFAULT X_MODE,  
    timeout           IN  INTEGER DEFAULT MAXWAIT,  
    release_on_commit IN  BOOLEAN DEFAULT FALSE)  
RETURN INTEGER;
```

The current default values, such as X\_MODE and MAXWAIT, are defined in the DBMS\_LOCK package specification.

### Parameters

**Table 103-10** REQUEST Function Parameters

| Parameter         | Description                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id or lockhandle  | User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by ALLOCATE_UNIQUE, of the lock mode you want to change                              |
| lockmode          | Mode that you are requesting for the lock.<br>For the available modes and their associated integer identifiers, see <a href="#">Constants</a> .                        |
| timeout           | Number of seconds to continue trying to grant the lock.<br>If the lock cannot be granted within this time period, then the call returns a value of 1 (timeout).        |
| release_on_commit | Set this parameter to TRUE to release the lock on commit or roll-back.<br>Otherwise, the lock is held until it is explicitly released or until the end of the session. |

### Return Values

**Table 103-11** REQUEST Function Return Values

| Return Value | Description                                    |
|--------------|------------------------------------------------|
| 0            | Success                                        |
| 1            | Timeout                                        |
| 2            | Deadlock                                       |
| 3            | Parameter error                                |
| 4            | Already own lock specified by id or lockhandle |
| 5            | Illegal lock handle                            |

# DBMS\_LOGMNR

The `DBMS_LOGMNR` package, one of a set of LogMiner packages, contains the subprograms you use to initialize the LogMiner tool and to begin and end a LogMiner session.

**Note:**

The ability to create flat file dictionary dumps of pluggable databases (PDBs) is desupported in Oracle Database 19c.

In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is now desupported. With Oracle Database 19c and later releases, Oracle recommends that you call `DBMS_LOGMNR.START_LOGMNR`, and supply the system change number (SCN) or time range that you want to mine. The SCN or time range options of `START_LOGMNR` are enhanced to support mining of individual PDBs.

The `CONTINUOUS_MINE` functionality of the LogMiner package is obsolete. It was deprecated in Oracle Database 12c release 2 (12.2). There is no replacement functionality.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)

- [Summary of DBMS\\_LOGMNR Subprograms](#)

**See Also:**

*Oracle Database Utilities* for information regarding LogMiner.

## 104.1 DBMS\_LOGMNR Overview

Oracle LogMiner, which is part of Oracle Database, enables you to query online and archived redo log files through a SQL interface. The `DBMS_LOGMNR` package provides the majority of the tools needed to start and stop LogMiner and specify the redo log files of interest.

All changes made to user data or to the database dictionary are recorded in the Oracle redo log files so that database recovery operations can be performed. You can take advantage of the data recorded in the redo log files to accomplish other tasks, such as:

- Pinpointing when a logical corruption to a database, such as errors made at the application level, may have begun
- Determining what actions you would have to take to perform fine-grained recovery at the transaction level.
- Performance tuning and capacity planning through trend analysis.
- Track any data manipulation language (DML) and data definition language (DDL) statements executed on the database, the order in which they were executed, and who executed them.

**See Also:**

[DBMS\\_LOGMNR\\_D](#) for information on the package subprograms that extract a LogMiner dictionary and re-create LogMiner tables in alternate tablespaces

## 104.2 DBMS\_LOGMNR Security Model

You must have the `EXECUTE_CATALOG_ROLE` role to use the `DBMS_LOGMNR` package.

## 104.3 DBMS\_LOGMNR Constants

The `DBMS_LOGMNR` package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name, for example, `DBMS_LOGMNR.NEW`.

**Note:**

The `continuous_mine` option for the `dbms_logmnr.start_logmnr` package is desupported in Oracle Database 19c (19.1), and is no longer available.

The following table describes the constants for the `ADD_LOGFILE options` flag in the `DBMS_LOGMNR` package.

**Table 104-1 Constants for ADD\_LOGFILE Options Flag**

| Constant | Description                                                                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NEW      | Implicitly calls the <code>DBMS_LOGMNR.END_LOGMNR</code> procedure to end the current LogMiner session and then creates a new session. The new session starts a new list of redo log files to be analyzed, beginning with the redo log file you specify. |
| ADDFILE  | Adds the specified redo log file to the list of redo log files to be analyzed. Any attempt to add a duplicate file raises an exception (ORA-01289). This is the default if no options flag is specified.                                                 |

[Table 104-2](#) describes the constants for the `START_LOGMNR options` flag in the `DBMS_LOGMNR` package.

**Table 104-2 Constants for START\_LOGMNR Options Flag**

| Constant                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMMITTED_DATA_ONLY      | <p>If set, DML statements corresponding to committed transactions are returned. DML statements corresponding to a committed transaction are grouped together. Transactions are returned in their commit order. Transactions that are rolled back or in-progress are filtered out, as are internal redo records (those related to index operations, management, and so on).</p> <p>If this option is not set, all rows for all transactions (committed, rolled back, and in-progress) are returned in the order in which they are found in the redo logs (in order of SCN values).</p> |
| SKIP_CORRUPTION          | <p>Directs a select operation on the V\$LOGMNR_CONTENTS view to skip any corruptions in the redo log file being analyzed and continue processing. This option works only when a block in the redo log file (and not the header of the redo log file) is corrupt. You should check the INFO column in the V\$LOGMNR_CONTENTS view to determine the corrupt blocks skipped by LogMiner. When a corruption in the redo log file is skipped, the OPERATION column contains the value CORRUPTED_BLOCKS, and the STATUS column contains the value 1343.</p>                                 |
| DDL_DICT_TRACKING        | <p>If the LogMiner dictionary in use is a flat file or in the redo log files, LogMiner updates its internal dictionary if a DDL event occurs. This ensures that correct SQL_REDO and SQL_UNDO information is maintained for objects that are modified after the LogMiner internal dictionary is built. The database to which LogMiner is connected must be open.</p> <p>This option cannot be used in conjunction with the DICT_FROM_ONLINE_CATALOG option and cannot be used when the LogMiner dictionary being used is one that was extracted to a flat file prior to Oracle9i.</p> |
| DICT_FROM_ONLINE_CATALOG | <p>Directs LogMiner to use the current online database dictionary rather than a LogMiner dictionary contained in a flat file or in the redo log files being analyzed.</p> <p>This option cannot be used in conjunction with the DDL_DICT_TRACKING option. The database to which LogMiner is connected must be the same one that generated the redo log files.</p> <p>Expect to see a value of 2 in the STATUS column of the V\$LOGMNR_CONTENTS view if the table definition in the database does not match the table definition in the redo log file.</p>                             |
| DICT_FROM_REDO_LOGS      | <p>If set, LogMiner expects to find a LogMiner dictionary in the redo log files that were specified. The redo log files are specified with the DBMS_LOGMNR.ADD_LOGFILE procedure or with the DBMS_LOGMNR.START_LOGMNR procedure.</p>                                                                                                                                                                                                                                                                                                                                                  |
| NO_SQL_DELIMITER         | <p>If set, the SQL delimiter (a semicolon) is not placed at the end of reconstructed SQL statements. This is helpful for applications that open a cursor and then execute the reconstructed statements.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| NO_ROWID_IN_STMT         | <p>If set, the ROWID clause is not included in the reconstructed SQL statements. The redo log file may already contain logically unique identifiers for modified rows if supplemental logging is enabled.</p> <p>When using this option, you must be sure that supplemental logging was enabled in the source database at the appropriate level and that no duplicate rows exist in the tables of interest. LogMiner does not make any guarantee regarding the uniqueness of logical row identifiers.</p>                                                                             |
| PRINT_PRETTY_SQL         | <p>If set, LogMiner formats the reconstructed SQL statements for ease of reading. These reconstructed SQL statements are not executable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 104-2 (Cont.) Constants for START\_LOGMNR Options Flag**

| Constant                | Description                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------|
| STRING_LITERALS_IN_STMT | If set, SQL_REDO and SQL_UNDO use literals for numbers and datetime and interval column types. |

To specify more than one option, use a plus sign (+) between them. For example:

```
EXECUTE DBMS_LOGMNR.START_LOGMNR(OPTIONS => -  
    DBMS_LOGMNR.DDL_DICT_TRACKING + DBMS_LOGMNR.DICT_FROM_REDO_LOGS);
```

## 104.4 DBMS\_LOGMNR Views

The DBMS\_LOGMNR package uses the views listed under *Accessing Logminer Operational Information In Views in Oracle Database Utilities*.

### See Also:

*Oracle Database Utilities*

## 104.5 DBMS\_LOGMNR Operational Notes

A **LogMiner session** begins with a call to DBMS\_LOGMNR.ADD\_LOGFILE or DBMS\_LOGMNR.START\_LOGMNR (the former if you plan to specify log files explicitly; the latter if you plan to use continuous mining). The session ends with a call to DBMS\_LOGMNR.END\_LOGMNR.

Within a LogMiner session, you can specify the redo log files to be analyzed and the SCN or time range of interest; then you can issue SQL SELECT statements against the V\$LOGMNR\_CONTENTS view to retrieve the data of interest.

ADD\_LOGFILE Procedure must be invoked before START\_LOGMNR Procedure.

### Note:

You must add log files before filtering. Continuous logging is no longer supported. If logfiles have not been added that match the time or the SCN that you provide, then DBMS\_LOGMNR.START\_LOGMNR fails with the error ORA-01291: missing logfile.

## 104.6 Summary of DBMS\_LOGMNR Subprograms

This table lists the DBMS\_LOGMNR subprograms and briefly describes them.

In a multitenant container database (CDB) some subprograms must be called from the root. There may be other differences as well. See the individual subprogram descriptions for details.

**Table 104-3 DBMS\_LOGMNR Package Subprograms**

| Subprogram                               | Description                                                                                                                                                                                                                      |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_LOGFILE Procedure</a>    | Adds a redo log file to the existing or newly created list of redo log files for LogMiner to process, so that if a new list is created, this marks the beginning of a LogMiner session                                           |
| <a href="#">COLUMN_PRESENT Function</a>  | Call this function for any row returned from the <code>V\$LOGMNR_CONTENTS</code> view to determine if undo or redo column values exist for the column specified by the <code>column_name</code> input parameter to this function |
| <a href="#">END_LOGMNR Procedure</a>     | Finishes a LogMiner session                                                                                                                                                                                                      |
| <a href="#">MINE_VALUE Function</a>      | Call this function for any row returned from the <code>V\$LOGMNR_CONTENTS</code> view to retrieve the undo or redo column value of the column specified by the <code>column_name</code> input parameter to this function         |
| <a href="#">REMOVE_LOGFILE Procedure</a> | Removes a redo log file from the list of redo log files for LogMiner to process                                                                                                                                                  |
| <a href="#">START_LOGMNR Procedure</a>   | Initializes the LogMiner utility and starts LogMiner (unless the session was already started with a call to <code>DBMS_LOGMNR.ADD_LOGFILE</code> )                                                                               |

## 104.6.1 ADD\_LOGFILE Procedure

This procedure adds a file to an existing or newly created list of log files for LogMiner to process.

### Note:

The `continuous_mine` option for the `dbms_logmnr.start_logmnr` package is desupported in Oracle Database 19c (19.1), and is no longer available.

In a CDB, the `ADD_LOGFILE` procedure must be called from the root database. You must have the `LOGMINING` administrative privilege to use this procedure.

### Syntax

```
DBMS_LOGMNR.ADD_LOGFILE (  
    LogFileName      IN VARCHAR2,  
    options           IN BINARY_INTEGER default ADDFILE );
```

### Parameters

**Table 104-4 ADD\_LOGFILE Procedure Parameters**

| Parameter                | Description                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>LogFileName</code> | Specifies the name of the redo log file to add to the list of redo log files to be analyzed during this session. |

**Table 104-4 (Cont.) ADD\_LOGFILE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| options   | <p>Does one of the following:</p> <ul style="list-style-type: none"> <li>Starts a new LogMiner session and a new list of redo log files for analysis (DBMS_LOGMNR.NEW)</li> <li>Adds a file to an existing list of redo log files for analysis (DBMS_LOGMNR.ADDFILE)</li> </ul> <p>See <a href="#">Table 104-1</a>.</p> |

## Exceptions

**Table 104-5 ADD\_LOGFILE Procedure Exceptions**

| Exception | Description                                                                                  |
|-----------|----------------------------------------------------------------------------------------------|
| ORA-01284 | Specified file cannot be opened.                                                             |
| ORA-01287 | Specified file is from a different database incarnation.                                     |
| ORA-01289 | Specified file has already been added to the list. Duplicate redo log files cannot be added. |
| ORA-01290 | Specified file is not in the current list and therefore cannot be removed from the list.     |
| ORA-01324 | Specified file cannot be added to the list because there is a DB_ID mismatch.                |

## Usage Notes

- The DBMS\_LOGMNR.ADD\_LOGFILE call from a PDB connection is not supported for adhoc users and returns error 65040.
- Dumping Flat File dictionary and mining using Flat File dictionary are not supported from a PDB connection.
- Before querying the V\$LOGMNR\_CONTENTS view, you must make a successful call to the DBMS\_LOGMNR.START\_LOGMNR procedure (within the current LogMiner session).
- The LogMiner session must be set up with a list of redo log files to be analyzed. Use the ADD\_LOGFILE procedure to specify the list of redo log files to analyze.
- If you want to analyze more than one redo log file, you must call the ADD\_LOGFILE procedure separately for each redo log file. The redo log files do not need to be registered in any particular order.
- Both archived and online redo log files can be mined.
- After you have added the first redo log file to the list, each additional redo log file that you add to the list must be associated with the same database and database RESETLOGS SCN as the first redo log file. (The database RESETLOGS SCN uniquely identifies each execution of an ALTER DATABASE OPEN RESETLOGS statement. When the online redo logs are reset, Oracle creates a new and unique incarnation of the database.)
- To analyze the redo log files from a different database (or a database incarnation with a different database RESETLOGS SCN) than that with which the current list of redo log files is associated, use the END\_LOGMNR procedure to end the current LogMiner session, and then build a new list using the ADD\_LOGFILE procedure.

- LogMiner matches redo log files by the log sequence number. Thus, two redo log files with different names but with the same log sequence number will return the ORA-01289 exception. For instance, the online counterpart of an archived redo log file has a different name from the archived redo log file, but attempting to register it with LogMiner after registering the archived counterpart will result in the ORA-01289 exception being returned.

## 104.6.2 COLUMN\_PRESENT Function

This function is designed to be used in conjunction with the `MINE_VALUE` function.

If the `MINE_VALUE` function returns a `NULL` value, it can mean either:

- The specified column is not present in the redo or undo portion of the data.
- The specified column is present and has a `NULL` value.

To distinguish between these two cases, use the `COLUMN_PRESENT` function, which returns a 1 if the column is present in the redo or undo portion of the data. Otherwise, it returns a 0.

### Syntax

```
DBMS_LOGMNR.COLUMN_PRESENT (
    sql_redo_undo      IN RAW,
    column_name        IN VARCHAR2 default '') RETURN NUMBER;
```

### Parameters

**Table 104-6 COLUMN\_PRESENT Function Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sql_redo_undo</code> | Specifies either the <code>REDO_VALUE</code> or the <code>UNDO_VALUE</code> column in the <code>V\$LOGMNR_CONTENTS</code> view from which to extract data values. See the Usage Notes for more information.                                         |
| <code>column_name</code>   | Specifies the fully qualified name ( <code>schema.table.column</code> ) of the column for which this function will return information.<br><br>In a CDB, the column name is specified as follows:<br><code>container_name:schema.table.column</code> |

### Return Values

[Table 104-7](#) describes the return values for the `COLUMN_PRESENT` function. The `COLUMN_PRESENT` function returns 1 if the self-describing record (the first parameter) contains the column specified in the second parameter. This can be used to determine the meaning of `NULL` values returned by the `DBMS_LOGMNR.MINE_VALUE` function.

**Table 104-7 Return Values for COLUMN\_PRESENT Function**

| Return | Description                                                                      |
|--------|----------------------------------------------------------------------------------|
| 0      | Specified column is not present in this row of <code>V\$LOGMNR_CONTENTS</code> . |
| 1      | Column is present in this row of <code>V\$LOGMNR_CONTENTS</code> .               |

## Exceptions

**Table 104-8** COLUMN\_PRESENT Function Exceptions

| Exception | Description                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01323 | Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session. |
| ORA-00904 | Value specified for the <code>column_name</code> parameter is not a fully qualified column name.                                               |

## Usage Notes

- To use the `COLUMN_PRESENT` function, you must have successfully started LogMiner.
- The `COLUMN_PRESENT` function must be invoked in the context of a select operation on the `V$LOGMNR_CONTENTS` view.
- The `COLUMN_PRESENT` function does not support `LONG`, `LOB`, `ADT`, or `COLLECTION` datatypes.
- The value for the `sql_redo_undo` parameter depends on the operation performed and the data of interest:
  - If an update operation was performed and you want to know what the value was prior to the update operation, specify `UNDO_VALUE`.
  - If an update operation was performed and you want to know what the value is after the update operation, specify `REDO_VALUE`.
  - If an insert operation was performed, typically you would specify `REDO_VALUE` (because the value of a column prior to an insert operation will always be `NULL`).
  - If a delete operation was performed, typically you would specify `UNDO_VALUE` (because the value of a column after a delete operation will always be `NULL`).

## 104.6.3 END\_LOGMNR Procedure

This procedure finishes a LogMiner session. Because this procedure performs cleanup operations that may not otherwise be done, you must use it to properly end a LogMiner session. This procedure is called automatically when you log out of a database session or when you call `DBMS_LOGMNR.ADD_LOGFILE` and specify the `NEW` option.

## Syntax

```
DBMS_LOGMNR.END_LOGMNR;
```

## Exceptions

**Table 104-9** END\_LOGMNR Procedure Exception

| Exception | Description                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01307 | No LogMiner session is currently active. The <code>END_LOGMNR</code> procedure was called without adding any log files or before the <code>START_LOGMNR</code> procedure was called |

## 104.6.4 MINE\_VALUE Function

This function facilitates queries based on a column's data value.

This function takes two arguments. The first one specifies whether to mine the redo (REDO\_VALUE) or undo (UNDO\_VALUE) portion of the data. The second argument is a string that specifies the fully qualified name of the column to be mined. The MINE\_VALUE function always returns a string that can be converted back to the original datatype.

### Syntax

```
DBMS_LOGMNR.MINE_VALUE (  
    sql_redo_undo    IN  RAW,  
    column_name      IN  VARCHAR2 default '') RETURN VARCHAR2;
```

### Parameters

**Table 104-10** MINE\_VALUE Function Parameters

| Parameter     | Description                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sql_redo_undo | Specifies either the REDO_VALUE or the UNDO_VALUE column in the V\$LOGMNR_CONTENTS view from which to extract data values. See the Usage Notes for more information.                                                |
| column_name   | Specifies the fully qualified name (schema.table.column) of the column for which this function will return information.<br>In a CDB, the column name is specified as follows:<br>container_name:schema.table.column |

### Return Values

**Table 104-11** Return Values for MINE\_VALUE Function

| Return   | Description                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NULL     | The column is not contained within the self-describing record, or the column value is NULL. To distinguish between the two different null possibilities, use the DBMS_LOGMNR.COLUMN_PRESENT function. |
| NON-NULL | The column is contained within the self-describing record; the value is returned in string format.                                                                                                    |

### Exceptions

**Table 104-12** MINE\_VALUE Function Exceptions

| Exception | Description                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01323 | Invalid state. Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session. |
| ORA-00904 | Invalid identifier. The value specified for the column_name parameter was not a fully qualified column name.                                                  |

### Usage Notes

- To use the `MINE_VALUE` function, you must have successfully started LogMiner.
- The `MINE_VALUE` function must be invoked in the context of a select operation from the `V$logmnr_contents` view.
- The `MINE_VALUE` function does not support `LONG`, `LOB`, `ADT`, or `COLLECTION` datatypes.
- The value for the `sql_redo_undo` parameter depends on the operation performed and the data of interest:
  - If an update operation was performed and you want to know what the value was prior to the update operation, specify `UNDO_VALUE`.
  - If an update operation was performed and you want to know what the value is after the update operation, specify `REDO_VALUE`.
  - If an insert operation was performed, typically you would specify `REDO_VALUE` (because the value of a column prior to an insert operation will always be null).
  - If a delete operation was performed, typically you would specify `UNDO_VALUE` (because the value of a column after a delete operation will always be null).
- If the `DBMS_LOGMNR.MINE_VALUE` function is used to get an `NCHAR` value that includes characters not found in the database character set, then those characters are returned as the replacement character (for example, an inverted question mark) of the database character set.

## 104.6.5 REMOVE\_LOGFILE Procedure

This procedure removes a redo log file from an existing list of redo log files for LogMiner to process.

In a CDB, the `REMOVE_LOGFILE` procedure must be called from the root database. You must have the `LOGMINING` administrative privilege to use this procedure.

### Syntax

```
DBMS_LOGMNR.REMOVE_LOGFILE (  
    LogFileName      IN VARCHAR2);
```

### Parameters

**Table 104-13 REMOVE\_LOGFILE Procedure Parameters**

| Parameter   | Description                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------|
| LogFileName | Specifies the name of the redo log file to be removed from the list of redo log files to be analyzed during this session. |

### Exceptions

**Table 104-14 REMOVE\_LOGFILE Procedure Exception**

| Exception | Description                     |
|-----------|---------------------------------|
| ORA-01290 | Cannot remove unlisted log file |

### Usage Notes

- Before querying the `V$LOGMNR_CONTENTS` view, you must make a successful call to the `DBMS_LOGMNR.START_LOGMNR` procedure (within the current LogMiner session).
- You can use this procedure to remove a redo log file from the list of redo log files for LogMiner to process if you know that redo log file does not contain any data of interest.
- Multiple redo log files can be removed by calling this procedure repeatedly.
- The redo log files do not need to be removed in any particular order.
- To start a new list of redo log files for analysis, use the `END_LOGMNR` procedure to end the current LogMiner session, and then build a new list using the `ADD_LOGFILE` procedure.
- Even if you remove all redo log files from the list, any subsequent calls you make to the `ADD_LOGFILE` procedure must match the database ID and `RESETLOGS SCN` of the removed redo log files. Therefore, to analyze the redo log files from a different database (or a database incarnation with a different database `RESETLOGS SCN`) than that with which the current list of redo log files is associated, use the `END_LOGMNR` procedure to end the current LogMiner session, and then build a new list using the `ADD_LOGFILE` procedure.

## 104.6.6 START\_LOGMNR Procedure

This procedure starts LogMiner by loading the dictionary that LogMiner will use to translate internal schema object identifiers to names.

In a CDB, the `START_LOGMNR` procedure must be called from the root database. You must have the `LOGMINING` administrative privilege to use this procedure.

### Note:

The ability to create flat file dictionary dumps of pluggable databases (PDBs) is desupported in Oracle Database 21c.

In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is now desupported. Starting with Oracle Database 21c, Oracle recommends that you call `DBMS_LOGMNR.START_LOGMNR`, and supply the system change number (SCN) or time range that you want to mine. The `SCN` or time range options of `START_LOGMNR` are enhanced to support mining of individual PDBs.

### Syntax

```
DBMS_LOGMNR.START_LOGMNR (  
    startScn          IN NUMBER default 0,  
    endScn            IN NUMBER default 0,  
    startTime         IN DATE default '01-jan-1988',  
    endTime           IN DATE default '31-dec-2110',  
    DictFileName      IN VARCHAR2 default '',  
    Options           IN BINARY_INTEGER default 0 );
```

## Parameters

**Table 104-15 START\_LOGMNR Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| startScn     | Directs LogMiner to return only redo records with an SCN greater than or equal to the startScn specified. This fails if there is no redo log file containing the specified startScn value. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V\$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)                                                                                                                                                                                                      |
| endScn       | Directs LogMiner to return only redo records with an SCN less than or equal to the endScn specified. If you specify an endScn value that is beyond the value in any redo log file, then LogMiner uses the greatest endScn value in the redo log file that contains the most recent changes. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V\$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)                                                                                                     |
| startTime    | Directs LogMiner to return only redo records with a timestamp greater than or equal to the startTime specified. This fails if there is no redo log file containing the specified startTime value. (You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V\$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.)<br>This parameter is ignored if startScn is specified. See the Usage Notes for additional information.                                                                                              |
| endTime      | Directs LogMiner to return only redo records with a timestamp less than or equal to the endTime specified. If you specify an endTime value that is beyond the value in any redo log file, then LogMiner will use the greatest endTime in the redo log file that contains the most recent changes. You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V\$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.)<br>This parameter is ignored if endScn is specified. See the Usage Notes for additional information. |
| DictFileName | Specifies the flat file that contains the LogMiner dictionary. It is used to reconstruct SQL_REDO and SQL_UNDO columns in V\$LOGMNR_CONTENTS, as well as to fully translate SEG_NAME, SEG_OWNER, SEG_TYPE_NAME, TABLE_NAME, and TABLE_SPACE columns. The fully qualified path name for the LogMiner dictionary file must be specified. (This file must have been created previously through the DBMS_LOGMNR.D.BUILD procedure.)<br>You need to specify this parameter only if neither DICT_FROM_REDO_LOGS nor DICT_FROM_ONLINE_CATALOG is specified.                                |
| options      | See <a href="#">Table 104-2</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Exceptions

**Table 104-16 START\_LOGMNR Procedure Exceptions**

| Exception | Description                                                                             |
|-----------|-----------------------------------------------------------------------------------------|
| ORA-01280 | Internal error encountered.                                                             |
| ORA-01281 | startScn or endScn parameter value is not a valid SCN, or endScn is less than startScn. |

**Table 104-16 (Cont.) START\_LOGMNR Procedure Exceptions**

| Exception | Description                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01282 | value for the <code>startTime</code> parameter was greater than the value specified for the <code>endTime</code> parameter, or there was no redo log file that was compatible with the date range specified with the <code>startTime</code> and <code>endTime</code> parameters. |
| ORA-01283 | Options parameter specified is invalid.                                                                                                                                                                                                                                          |
| ORA-01284 | LogMiner dictionary file specified in the <code>DictFileName</code> parameter has a full path length greater than 256 characters, or the file cannot be opened.                                                                                                                  |
| ORA-01285 | Error reading specified file.                                                                                                                                                                                                                                                    |
| ORA-01291 | Redo log files that are needed to satisfy the user's requested SCN or time range are missing.                                                                                                                                                                                    |
| ORA-01292 | No log file has been specified for the current LogMiner session.                                                                                                                                                                                                                 |
| ORA-01293 | Mounted database required for specified LogMiner options.                                                                                                                                                                                                                        |
| ORA-01294 | Error occurred while processing information in the specified dictionary file, possible corruption.                                                                                                                                                                               |
| ORA-01295 | Specified LogMiner dictionary does not correspond to the database that produced the log files being analyzed.                                                                                                                                                                    |
| ORA-01296 | Character set mismatch between specified LogMiner dictionary and log files.                                                                                                                                                                                                      |
| ORA-01297 | Redo version mismatch between LogMiner dictionary and log files.                                                                                                                                                                                                                 |
| ORA-01299 | Specified LogMiner dictionary corresponds to a different database incarnation.                                                                                                                                                                                                   |
| ORA-01300 | Writable database required for specified LogMiner options.                                                                                                                                                                                                                       |

**Usage Notes****Note:**

The `continuous_mine` option for the `dbms_logmnr.start_logmnr` package is desupported in Oracle Database 19c (19.1), and is no longer available.

- The `DBMS_LOGMNR.ADD_LOGFILE` call from a PDB connection is not supported for adhoc users and returns error 65040.
- Users can specify the SCN range or the time range. The required logfiles will be added programmatically.
- Dumping Flat File dictionary and mining using Flat File dictionary are not supported from a PDB connection.
- LogMiner can use a dictionary that you previously extracted to the redo log files or to a flat file, or you can specify that LogMiner use the online catalog if LogMiner is mining data from the source system.
- After executing the `START_LOGMNR` procedure, you can query the following views:
  - `V$LOGMNR_CONTENTS` - contains history of information in redo log files

- V\$LOGMNR\_DICTIONARY - contains current information about the LogMiner dictionary file extracted to a flat file
- V\$LOGMNR\_PARAMETERS - contains information about the LogMiner session

(You can query the V\$LOGMNR\_LOGS view after a redo log file list has been added to the list of files that LogMiner is to mine.)

- Parameters and options are not persistent across calls to DBMS\_LOGMNR.START\_LOGMNR. You must specify all desired parameters and options (including SCN and time ranges) each time you call DBMS\_LOGMNR.START\_LOGMNR
- Be aware that specifying redo log files using a timestamp is not precise.
- Keep the following in mind regarding starting and ending times or SCN ranges:
  - If you specify neither a `startTime` nor a `startScn` parameter, LogMiner will set the `startScn` parameter to use the lowest SCN value from the redo log file that contains the oldest changes.
  - If you specify both time and SCN values, LogMiner uses the SCN value or values and ignores the time values.
  - If you specify starting and ending time or SCN values and they are found in the LogMiner redo log file list, then LogMiner mines the logs indicated by those values.
  - If you specify starting and ending times or SCN values that are not in the LogMiner redo log file list, and you specify DBMS\_LOGMNR.START\_LOGMNR, and you specify:
    - \* 0 for the `startTime` or `startScn` value, then the lowest SCN in the LogMiner redo log file list will be used as the `startScn`
    - \* A nonzero number for the `startTime` or `startScn` value, then an error is returned
    - \* 0 or a nonzero number for the `endTime` or `endScn` value, then the highest SCN in the LogMiner redo log file list will be used as the `endScn`
  - If you specify starting and ending times or SCN values and they are not found in the LogMiner redo log file list, and you specify DBMS\_LOGMNR.START\_LOGMNR, and you specify:
    - \* 0 for the `startTime` or `startScn` value, then an error is returned.
    - \* A `startTime` or `startScn` value that is greater than any value in the database's archived redo log files, then LogMiner starts mining in the online redo log file. LogMiner will continue to process the online redo log file until it finds a change at, or beyond, the requested starting point before it returns rows from the V\$LOGMNR\_CONTENTS view.
    - \* An `endTime` or `endScn` parameter value that indicates a time or SCN in the future, then LogMiner includes the online redo log files when it mines. When you query the V\$LOGMNR\_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until LogMiner sees a change beyond the requested ending point.
    - \* 0 for the `endTime` or `endScn` parameter value, then LogMiner includes the online redo log files when it mines. When you query the V\$LOGMNR\_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until you enter CTL+C or you terminate the PL/SQL cursor.

# DBMS\_LOGSTDBY

The `DBMS_LOGSTDBY` package provides subprograms for configuring and managing the logical standby database environment.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_LOGSTDBY Subprograms](#)

## See Also:

*Oracle Data Guard Concepts and Administration*

## 105.1 DBMS\_LOGSTDBY Overview

The `DBMS_LOGSTDBY` package helps you manage the SQL Apply (logical standby database) environment.

The subprograms in the `DBMS_LOGSTDBY` package help you to accomplish the following main objectives:

- Manage configuration parameters used by SQL Apply.  
For example, controlling how transactions are applied on the logical standby database, how much shared pool is used, and how many processes are used by SQL Apply to mine and apply the changes.
- Ensure an appropriate level of supplemental logging is enabled, and a LogMiner dictionary is built correctly for logical standby database creation.
- Provide a way to skip the application of changes to selected tables or entire schemas in the logical standby database, and specify ways to handle exceptions encountered by SQL Apply.
- Allow controlled access to tables in the logical standby database that may require maintenance.

## 105.2 DBMS\_LOGSTDBY Security Model

You must have the `DBA` role to use the `DBMS_LOGSTDBY` package.

A prototype role, `LOGSTDBY_ADMINISTRATOR`, is created by default with `RESOURCE` and `EXECUTE` privileges on `DBMS_LOGSTDBY`. If you choose to use this role, consider granting `ALTER DATABASE` and `ALTER SESSION` privileges to the role so that the grantee can start and stop SQL Apply and can enable and disable the database guard.

The procedures associated with skipping transactions (SKIP and UNSKIP, SKIP\_ERROR and UNSKIP\_ERROR, and SKIP\_TRANSACTION and UNSKIP\_TRANSACTION) all require DBA privileges to execute because their scope may contain wildcard schemas. Oracle recommends that where SKIP procedures are specified, these be owned by a secure account with appropriate privileges on the schemas they act on (for example, SYS).

## 105.3 DBMS\_LOGSTDBY Constants

The DBMS\_LOGSTDBY package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name, for example, DBMS\_LOGSTDBY.SKIP\_ACTION\_SKIP.

The following table describes the constants for the `proc_name` parameter in the DBMS\_LOGSTDBY.SKIP procedure.

**Table 105-1 Constants for SKIP Options Flag**

| Constant            | Description                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAX_EVENTS          | Maximum number of events to log in the DBA_LOGSTDBY_EVENTS view. See the DBMS_LOGSTDBY <a href="#">APPLY_SET Procedure</a> .                                                                                                                                                                                                |
| SKIP_ACTION_APPLY   | Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to apply the DDL or PL/SQL statement.                                                                                     |
| SKIP_ACTION_ERROR   | Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to error out.                                                                                                             |
| SKIP_ACTION_REPLACE | Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to apply the replacement DDL. (This constant should not be used while handling an Oracle Supplied PL/SQL procedure call). |
| SKIP_ACTION_SKIP    | Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to skip the associated DDL or Oracle supplied PL/SQL procedure call.                                                      |

## 105.4 Summary of DBMS\_LOGSTDBY Subprograms

This table describes each subprogram of the DBMS\_LOGSTDBY procedure, including a reference to the section where each procedure is described in more detail.

In a multitenant container database (CDB), some subprograms must be called from the root. There may be other differences as well. See the individual subprogram descriptions for details.

**Table 105-2 DBMS\_LOGSTDBY Package Subprograms**

| Subprogram                          | Description                                                                  |
|-------------------------------------|------------------------------------------------------------------------------|
| <a href="#">APPLY_SET Procedure</a> | Sets the values of various parameters that configure and maintain SQL Apply. |

**Table 105-2 (Cont.) DBMS\_LOGSTDBY Package Subprograms**

| Subprogram                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">APPLY_UNSET Procedure</a>             | Restores the default values of various parameters that configure and maintain SQL Apply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <a href="#">BUILD Procedure</a>                   | Ensures supplemental logging is enabled properly and builds the LogMiner dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <a href="#">INSTANTIATE_TABLE Procedure</a>       | Creates and populates a table in the standby database from a corresponding table in the primary database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <a href="#">IS_APPLY_SERVER Function</a>          | This function returns <code>TRUE</code> if it is executed from PL/SQL in the context of a logical standby apply server process. This function is used in conjunction with triggers that have the <code>fire_once</code> parameter in the <code>DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY</code> subprogram set to <code>FALSE</code> (the default is <code>TRUE</code> ). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby. |
| <a href="#">MAP_PRIMARY_SCN Function</a>          | Maps an SCN relevant to the primary database to a corresponding SCN at the logical standby database. The mapped SCN is conservative in nature, and can thus be used to flash back the logical standby database to compensate for a flashback database operation performed at the primary database.                                                                                                                                                                                                                                                                                                             |
| <a href="#">PREPARE_FOR_NEW_PRIMARY Procedure</a> | Used after a failover, this procedure ensures a local logical standby database that was not involved in the failover has not processed more redo than the new primary database and reports the set of archive redo log files that must be replaced to ensure consistency                                                                                                                                                                                                                                                                                                                                       |
| <a href="#">PURGE_SESSION Procedure</a>           | Identifies the archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <a href="#">REBUILD Procedure</a>                 | Records relevant metadata (including the LogMiner dictionary) in the redo stream in case a database that has recently changed its role to a primary database following a failover operation fails to do so during the failover process                                                                                                                                                                                                                                                                                                                                                                         |
| <a href="#">SET_TABLESPACE Procedure</a>          | Moves metadata tables required by SQL Apply to the user-specified tablespace. By default, the metadata tables are created in the <code>SYS_AUX</code> tablespace.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <a href="#">SKIP Procedure</a>                    | Specifies rules that control database operations that should not be applied to the logical standby database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <a href="#">SKIP_ERROR Procedure</a>              | Specifies rules regarding what action to take upon encountering errors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <a href="#">SKIP_TRANSACTION Procedure</a>        | Specifies transactions that should not be applied on the logical standby database. Be careful in using this procedure, because not applying specific transactions may cause data corruption at the logical standby database.                                                                                                                                                                                                                                                                                                                                                                                   |
| <a href="#">UNSKIP Procedure</a>                  | Deletes rules specified by the <code>SKIP</code> procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <a href="#">UNSKIP_ERROR Procedure</a>            | Deletes rules specified by the <code>SKIP_ERROR</code> procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <a href="#">UNSKIP_TRANSACTION Procedure</a>      | Deletes rules specified by the <code>SKIP_TRANSACTION</code> procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 105.4.1 APPLY\_SET Procedure

Use this procedure to set values of parameters that configure and manage SQL Apply in a logical standby database environment. All parameters, except for `PRESERVE_COMMIT_ORDER`, can be changed without having to stop SQL Apply.

In a CDB, the `APPLY_SET` procedure must be called from the root database.

### Syntax

```
DBMS_LOGSTDBY.APPLY_SET (
    inname          IN VARCHAR,
    value           IN VARCHAR);
```

### Parameters

**Table 105-3 APPLY\_SET Procedure Parameters**

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>APPLY_SERVERS</code>                 | Controls the number of <code>APPLIER</code> processes used to apply changes. The maximum number allowed is 1024, provided the <code>MAX_SERVERS</code> parameter is set to accommodate this.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>EVENT_LOG_DEST</code>                | <p>Controls where SQL Apply records the occurrence of an interesting event. It takes the following values:</p> <ul style="list-style-type: none"> <li><code>DEST_ALL</code> - All events will be recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view and in the alert log.</li> <li><code>DEST_EVENTS_TABLE</code> - All events that contain information about user data will be recorded only in the <code>DBA_LOGSTDBY_EVENTS</code> view. This is the default value.</li> </ul> <p>For example, if SQL Apply receives an <code>ORA-1403</code> error, the whole event is recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view. Whereas, the alert log records only that SQL Apply stopped because of <code>ORA-1403</code>. No information regarding the user table or offending statement is logged in the alert log. However, if you stop the SQL Apply engine, it gets recorded in both the <code>DBA_LOGSTDBY_EVENTS</code> view and in the alert log.</p> <p>Note that this parameter affects the behavior of the following parameters: <code>RECORD_APPLIED_DDL</code>, <code>RECORD_SKIP_DDL</code>, <code>RECORD_SKIP_ERRORS</code>, and <code>RECORD_UNSUPPORTED_OPERATIONS</code>. For example, if <code>RECORD_APPLIED_DDL</code> is set to <code>TRUE</code>, but <code>EVENT_LOG_DEST</code> is set to <code>DEST_EVENTS_TABLE</code>, then the applied DDL string will only be recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view.</p> |
| <code>LOG_AUTO_DEL_RETENTION_TARGET</code> | This parameter setting is only meaningful if <code>LOG_AUTO_DELETE</code> has been set to <code>TRUE</code> . The value you supply for this parameter controls how long (in minutes) a remote archived log that is received from the primary database will be retained at the logical standby database once all redo records contained in the log have been applied at the logical standby database. The default value is 1440 minutes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 105-3 (Cont.) APPLY\_SET Procedure Parameters**

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOG_AUTO_DELETE       | Automatically deletes foreign archived redo log files as soon as they have been applied on the logical standby database. By default, a foreign archived redo log file is not deleted until 24 hours (the default value of LOG_AUTO_DEL_RETENTION_TARGET parameter) after it has been applied at the logical standby database. Set to TRUE to enable automatic deletion of archived redo log files. Set to FALSE to disable automatic deletion. The default value is TRUE.                                                                                                                                                          |
| MAX_EVENTS_RECORDED   | Number of recent events that will be visible through the DBA_LOGSTDBY_EVENTS view. To record all events encountered by SQL Apply, use the DBMS_LOGSTDBY.MAX_EVENTS constant as the number value. The default value is 10,000.                                                                                                                                                                                                                                                                                                                                                                                                      |
| MAX_SERVERS           | Number of processes that SQL Apply uses to read and apply redo. The default value is 9. The maximum number allowed is 2048.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| MAX_SGA               | Number of megabytes from shared pool in System Global Area (SGA) that SQL Apply will use. The default value is 30 megabytes or one quarter of the value set for SHARED_POOL_SIZE, whichever is lower. The maximum size allowed is 4095 megabytes.                                                                                                                                                                                                                                                                                                                                                                                  |
| PREPARE_SERVERS       | Controls the number of PREPARER processes used to prepare changes. The maximum number allowed is 1024, provided the MAX_SERVERS parameter is set to accommodate this.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PRESERVE_COMMIT_ORDER | <p>TRUE: Transactions are applied to the logical standby database in the exact order in which they were committed on the primary database. This is the default parameter setting.</p> <p>FALSE: Transactions containing non-overlapping sets of rows may be committed in a different order than they were committed on the primary database.</p> <p>Regardless of the level chosen, modifications done to the same row are always applied in the same order as they happened on the primary database. See the Usage Notes for details and recommendations.</p> <p>You cannot modify this parameter while SQL Apply is running.</p> |
| RECORD_APPLIED_DDL    | <p>Controls whether DDL statements that have been applied to the logical standby database are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values:</p> <p>TRUE: Indicates that DDL statements applied to the logical standby database are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log.</p> <p>FALSE: Indicates that applied DDL statements are not recorded. This is the default parameter setting.</p>                                                                                                                                                        |
| RECORD_SKIP_DDL       | <p>Controls whether skipped DDL statements are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values:</p> <p>TRUE: Skipped DDL statements are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log. This is the default parameter setting.</p> <p>FALSE: Skipped DDL statements are not recorded in the DBA_LOGSTDBY_EVENTS table and the alert log.</p>                                                                                                                                                                                                                  |

**Table 105-3 (Cont.) APPLY\_SET Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RECORD_SKIP_ERRORS            | Controls whether skipped errors (as described by the SKIP_ERROR procedure) are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values:<br><br>TRUE: Skipped errors are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log. This is the default parameter setting.<br><br>FALSE: Skipped errors are not recorded in the DBA_LOGSTDBY_EVENTS table and the alert log.   |
| RECORD_UNSUPPORTED_OPERATIONS | Captures information about transactions running on the primary database that will not be supported by a logical standby database. This procedure records its information as events in the DBA_LOGSTDBY_EVENTS table. Specify one of the following values:<br><br>TRUE: The information is captured and recorded as events in the DBA_LOGSTDBY_EVENTS table.<br><br>FALSE: The information is not captured. This is the default. |

If a parameter is changed while SQL Apply is running, the change will take effect at some point in the future. In such a case, an informational row is inserted into the DBA\_LOGSTDBY\_EVENTS view at the time the parameter change takes effect.

Additionally, if you are modifying a parameter while SQL Apply is running on an Oracle RAC configuration, you must be connected to the same instance where SQL Apply is running.

### Exceptions

**Table 105-4 APPLY\_SET Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |
| ORA-16236 | Logical Standby metadata operation in progress                |

### Usage Notes

- Use the APPLY\_UNSET procedure to restore the default settings of a parameter.
- See *Oracle Data Guard Concepts and Administration* for help with tuning SQL Apply and for information about setting appropriate values for different parameters.

### Examples

To record DDLs in the DBA\_LOGSTDBY\_EVENTS view and in the alert log, issue the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_SET('RECORD_APPLIED_DDL', TRUE);
```

## 105.4.2 APPLY\_UNSET Procedure

Use the `APPLY_UNSET` procedure to restore the default values of the parameters that you changed with the `APPLY_SET` procedure.

In a CDB, the `APPLY_UNSET` procedure must be called from the root database.

### Syntax

```
DBMS_LOGSTDBY.APPLY_UNSET (  
    inname          IN VARCHAR);
```

### Parameters

The parameter information for the `APPLY_UNSET` procedure is the same as that described for the `APPLY_SET` procedure. See [Table 105-3](#) for complete parameter information.

### Exceptions

**Table 105-5** `APPLY_UNSET` Procedure Exceptions

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |
| ORA-16236 | Logical Standby metadata operation in progress                |

### Usage Notes

- Use the `APPLY_SET` procedure to specify a nondefault value for a parameter.

### Examples

If you previously specified that applied DDLs show up in the `DBA_LOGSTDBY_EVENTS` view and the alert log, you can restore the default behavior of SQL Apply regarding applied DDL statements with the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_UNSET('RECORD_APPLIED_DDL');
```

## 105.4.3 BUILD Procedure

Use this procedure on the primary database to record relevant metadata (LogMiner dictionary) information in the redo log, which will subsequently be used by SQL Apply. This procedure will enable database-wide primary- and unique-key supplemental logging, if necessary.

In a CDB, the `BUILD` procedure must be called from the root database on the primary. Additionally, you cannot add or remove PDBs from a CDB while this procedure is executing.

**Note:**

In databases created using Oracle Database 11g release 2 (11.2) or later, supplemental logging information is automatically propagated to any existing physical standby databases. However, for databases in earlier releases, or if the database was created using an earlier release and then upgraded to 11.2, you must check whether supplemental logging is enabled at the physical standby(s) if it is also enabled at the primary database. If it is not enabled at the physical standby(s), then before performing a switchover or failover, you must enable supplemental logging on all existing physical standby databases. To do so, issue the following SQL command on each physical standby:

```
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY, UNIQUE INDEX)
      COLUMNS;
```

If you do not do this, then any logical standby that is also in the same Data Guard configuration will be unusable if a switchover or failover is performed to one of the physical standby databases. If a switchover or failover has already occurred and supplemental logging was not enabled, then you must recreate all logical standby databases.

**Syntax**

```
DBMS_LOGSTDBY.BUILD;
```

**Usage Notes**

- Supplemental log information includes extra information in the redo logs that uniquely identifies a modified row in the logical standby database, and also includes information that helps efficient application of changes to the logical standby database.
- LogMiner dictionary information allows SQL Apply to interpret data in the redo logs.
- DBMS\_LOGSTDBY.BUILD should be run only once for each logical standby database you want to create. You do not need to use DBMS\_LOGSTDBY.BUILD for each Oracle RAC instance.
- DBMS\_LOGSTDBY.BUILD waits for all transactions (including distributed transactions) that are active at the time of the procedure invocation to complete before returning. See *Oracle Database Administrator's Guide* for information about how to handle in-doubt transactions.

**Examples**

To build the LogMiner dictionary in the redo stream of the primary database and to record additional information so that a logical standby database can be instantiated, issue the following SQL statement at the primary database

```
SQL> EXECUTE DBMS_LOGSTDBY.BUILD;
```

## 105.4.4 INSTANTIATE\_TABLE Procedure

This procedure creates and populates a table in the standby database from a corresponding table in the primary database.

The table requires the name of the database link (*dblink*) as an input parameter. If the table already exists in the logical standby database, it will be dropped and re-created based on the

table definition at the primary database. This procedure only brings over the data associated with the table, and not the associated indexes and constraints.

Use the `INSTANTIATE_TABLE` procedure to:

- Add a table to a standby database.
- Re-create a table in a standby database.

In a CDB, the `INSTANTIATE_TABLE` procedure must be called from within the container in which the table to be instantiated resides. Additionally, the database link that is provided to the primary database must point to the corresponding container on the primary.

### Syntax

```
DBMS_LOGSTDBY.INSTANTIATE_TABLE (
    schema_name      IN VARCHAR2,
    table_name       IN VARCHAR2,
    dblink           IN VARCHAR2);
```

### Parameters

**Table 105-6** INSTANTIATE\_TABLE Procedure Parameters

| Parameter                | Description                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schema_name</code> | Name of the schema                                                                                                                                                                |
| <code>table_name</code>  | Name of the table to be created or re-created in the standby database                                                                                                             |
| <code>dblink</code>      | Name of the database link account that has privileges to read and lock the table in the primary database, as well as the <code>SELECT_CATALOG_ROLE</code> on the primary database |

### Exceptions

**Table 105-7** INSTANTIATE\_TABLE Procedure Exceptions

| Exception | Description                                                     |
|-----------|-----------------------------------------------------------------|
| ORA-16103 | Logical Standby apply must be stopped to allow this operation   |
| ORA-16236 | Logical Standby metadata operation in progress                  |
| ORA-16276 | Specified database link does not correspond to primary database |
| ORA-16277 | Specified table is not supported by logical standby database    |
| ORA-16278 | Specified table has a multi-object skip rule defined            |

### Usage Notes

- Use this procedure to create and populate a table in a way that keeps the data on the standby database transactionally consistent with the primary database.
- This table will not be synchronized with the rest of the tables being maintained by SQL Apply and SQL Apply will not start to maintain it until SQL Apply encounters redo that occurred after the table was instantiated from the primary. The SCN at which the table was instantiated from the primary database is available in the `DBA_LOGSTDBY_EVENTS` view.
- The specified table must be a table that is supported by logical standby (that is, it does not appear in the `DBA_LOGSTDBY_UNSUPPORTED_TABLES` view on the primary database).

- If there are any skip rules that specifically name this table (without any wildcards), those skip rules will be dropped as part of `INSTANTIATE_TABLE`, so that the table will be properly maintained by SQL Apply in the future. If there are skip rules that indirectly reference this table (match a skip rule with a wildcard in the `schema_name` or `table_name`, and have a `TABLE`, `DML`, or `SCHEMA_DDL` statement type), `INSTANTIATE_TABLE` will fail with an ORA-16278 error. Any multi-object skip rules that pertain to the table must be dropped or changed before re-attempting the `INSTANTIATE_TABLE` call.

### Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.INSTANTIATE_TABLE (-
    SCHEMA_NAME => 'HR', TABLE_NAME => 'EMPLOYEES', -
    DBLINK => 'INSTANTIATE_TBL_LINK');
```

## 105.4.5 IS\_APPLY\_SERVER Function

This function returns `TRUE` if it is executed from PL/SQL in the context of a logical standby apply server process.

This function is used in conjunction with triggers that have the `fire_once` parameter in the `DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY` subprogram set to `FALSE` (the default is `TRUE`). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby.

### Syntax

```
DBMS_LOGSTDBY.IS_APPLY_SERVER
RETURN BOOLEAN;
```

### Parameters

None

## 105.4.6 MAP\_PRIMARY\_SCN Function

This function returns an SCN on the standby that predates the supplied SCN from the primary database by at least 5 minutes.

It can be used to determine a safe SCN to use in a compensating flashback database operation at the logical standby database, following a flashback database operation or a point-in-time recovery operation at the primary database.

### Syntax

```
DBMS_LOGSTDBY.MAP_PRIMARY_SCN(primary_scn NUMBER) RETURN NUMBER;
```

### Exceptions

**Table 105-8 MAP\_PRIMARY\_SCN Function Exceptions**

| Exception | Description                                                                     |
|-----------|---------------------------------------------------------------------------------|
| ORA-20001 | Primary SCN is before mapped range                                              |
| ORA-20002 | SCN mapping requires <code>PRESERVE_COMMIT_ORDER</code> to be <code>TRUE</code> |

## Usage Notes

Use this function to get a conservative SCN at the logical standby database that corresponds to an SCN at the primary database. This function is useful in the context of doing compensating flashback database operations at the logical standby following a flashback database or a point-in-time recovery operation done at the primary database.

## 105.4.7 PREPARE\_FOR\_NEW\_PRIMARY Procedure

The `PREPARE_FOR_NEW_PRIMARY` procedure must be invoked at a logical standby database following a failover, if that standby database was not the target of the failover operation.

Such a standby database must process the exact same set of redo logs processed at the new primary database. This routine ensures that the local logical standby database has not processed more redo than the new primary database and reports the set of archive logs that must be replaced to ensure consistency. The set of replacement logs will be reported in the alert.log. These logs must be copied to the logical standby and registered using the `ALTER DATABASE REGISTER LOGICAL LOGFILE` statement.

In a CDB, the `PREPARE_FOR_NEW_PRIMARY` procedure must be called from the root database.

## Syntax

```
DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY (
    FORMER_STANDBY_TYPE    IN VARCHAR2,
    DBLINK                 IN VARCHAR2);
```

## Parameters

**Table 105-9 PREPARE\_FOR\_NEW\_PRIMARY Procedure Parameters**

| Parameter           | Description                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORMER_STANDBY_TYPE | The type of standby database that was the target of the failover operation to become the new primary database. Valid values are 'PHYSICAL' if the new primary was formerly a physical standby, and 'LOGICAL' if the new primary database was formerly a logical standby database. |
| DBLINK              | The name of a database link to the new primary database                                                                                                                                                                                                                           |

## Exceptions

**Table 105-10 PREPARE\_FOR\_NEW\_PRIMARY Procedure Exceptions**

| Exception | Description                                     |
|-----------|-------------------------------------------------|
| ORA-16104 | Invalid Logical Standby option.                 |
| ORA-16109 | Failed to apply log data from previous primary. |

## Usage Notes

- This routine is intended only for logical standby systems. This routine will fail if the new primary database was formerly a logical standby database and the LogMiner dictionary build has not completed successfully. Log files displayed in the alert log will be referred to as *terminal logs*. Users should keep in mind that file paths are relative to the new primary

database and may not resolve locally. Upon manual registration of the terminal logs, users should complete the process by calling either `START LOGICAL STANDBY APPLY` if the new primary database was formerly a physical standby database or `START LOGICAL STANDBY APPLY NEW PRIMARY` if the new primary database was formerly a logical standby database. See the alert log for more details regarding the reasons for any exception.

### Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY ( -  
        FORMER_STANDBY_TYPE => 'LOGICAL', -  
        DBLINK => 'dblink_to_newprimary');
```

## 105.4.8 PURGE\_SESSION Procedure

`PURGE_SESSION` identifies all archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply.

Once identified, you can issue operating system commands to delete some or all of the unnecessary archived redo log files.

In a CDB, the `PURGE_SESSION` procedure must be called from the root database.

### Syntax

```
DBMS_LOGSTDBY.PURGE_SESSION;
```

### Exceptions

**Table 105-11** `PURGE_SESSION` Procedure Exceptions

| Exception | Description     |
|-----------|-----------------|
| ORA-01309 | Invalid session |

### Usage Notes

- This procedure does not delete the archived redo log files. You must issue operating system commands to delete unneeded files.
- This procedure updates the `DBA_LOGMNR_PURGED_LOG` view that displays the archived redo log files that have been applied to the logical standby database.
- In Oracle Database 10g Release 2, metadata related to the archived redo log files (and the actual archived redo log files) are purged automatically based on the default setting of the `LOG_AUTO_DELETE` parameter described in the `DBMS_LOGSTDBY.APPLY_SET` procedure described.

### Example

To identify and remove unnecessary files:

1. Enter the following statement on the logical standby database:

```
SQL> EXECUTE DBMS_LOGSTDBY.PURGE_SESSION;
```

2. Query the `DBA_LOGMNR_PURGED_LOG` view to list the archived redo log files that can be removed:

```
SQL> SELECT * FROM DBA_LOGMNR_PURGED_LOG;
```

```
FILE_NAME
-----
/boston/arc_dest/arc_1_40_509538672.log
/boston/arc_dest/arc_1_41_509538672.log
/boston/arc_dest/arc_1_42_509538672.log
/boston/arc_dest/arc_1_43_509538672.log
/boston/arc_dest/arc_1_44_509538672.log
/boston/arc_dest/arc_1_45_509538672.log
/boston/arc_dest/arc_1_46_509538672.log
/boston/arc_dest/arc_1_47_509538672.log
```

3. Use operating system-specific commands to delete archived redo log files from the file system.

## 105.4.9 REBUILD Procedure

This procedure is used if a database that has recently changed its role to a primary database following a failover operation fails to record relevant metadata (including the LogMiner dictionary) in the redo stream required for other logical standby databases.

In a CDB, the `REBUILD` procedure must be called from the root database.

### Syntax

```
DBMS_LOGSTDBY.REBUILD;
```

### Usage Notes

- LogMiner dictionary information is logged in the redo log files. The standby redo log files (if present) are archived.

### Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.REBUILD;
```

## 105.4.10 SET\_TABLESPACE Procedure

This procedure moves metadata tables required by SQL Apply to the user-specified tablespace.

By default, the metadata tables are created in the `SYSAUX` tablespace. SQL Apply cannot be running when you invoke this procedure.

In a CDB, the `SET_TABLESPACE` procedure must be called from the root database.

### Syntax

```
DBMS_LOGSTDBY.SET_TABLESPACE(
    NEW_TABLESPACE IN VARCHAR2)
```

### Parameters

**Table 105-12 SET\_TABLE SPACE Procedure Parameters**

| Parameter                   | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <code>NEW_TABLESPACE</code> | Name of the new tablespace where metadata tables will reside. |

## Exceptions

**Table 105-13 SET\_TABLESPACE Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16236 | Logical Standby metadata operation in progress                |

## Examples

To move metadata tables to a new tablespace named LOGSTDBY\_TBS, issue the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.SET_TABLESPACE (new_tablespace => 'LOGSTDBY_TBS');
```

## 105.4.11 SKIP Procedure

The `SKIP` procedure can be used to define rules that will be used by SQL Apply to skip the application of certain changes to the logical standby database.

For example, the `SKIP` procedure can be used to skip changes to a subset of tables in the logical standby database. It can also be used to specify DDL statements that should not be applied at the logical standby database or should be modified before they are applied in the logical standby database. One reason why a DDL statement may need to be modified is to accommodate a different directory structure on the logical standby database.

### Note:

For information about skipping containers, see "[Skipping Containers](#)."

## Syntax

```
DBMS_LOGSTDBY.SKIP (  
    stmt                IN VARCHAR2,  
    schema_name         IN VARCHAR2 DEFAULT NULL,  
    object_name         IN VARCHAR2 DEFAULT NULL,  
    proc_name           IN VARCHAR2 DEFAULT NULL,  
    use_like            IN BOOLEAN DEFAULT TRUE,  
    esc                 IN CHAR1 DEFAULT NULL);
```

## Parameters

**Table 105-14 SKIP Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stmt        | <p>Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration since keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. <a href="#">Table 105-15</a> shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter.</p> <p>The keyword <code>PL/SQL</code> is used for the execution of Oracle-supplied packages which are supported for replication.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| use_like  | Allows pattern matching to isolate the tables that you want to skip on the logical standby database. The use_like parameter matches a portion of one character value to another by searching the first value for the pattern specified by the second, and calculates strings using characters as defined by the input character set. This parameter follows the same rules for pattern matching described in <i>Oracle Database SQL Language Reference</i> . |
| esc       | Identifies an escape character (such as the character "/") that you can use for pattern matching. If the escape character appears in the pattern before the character "%" or "_" then Oracle interprets this character literally in the pattern, rather than as a special pattern matching character. See <i>Oracle Database SQL Language Reference</i> for more information about pattern matching.                                                         |

**Usage Notes**

- This procedure requires DBA privileges to execute.
- You cannot associate a stored procedure to be invoked in the context of a DML statement. For example, the following statement returns the ORA-16104: invalid Logical Standby option requested error:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
      stmt => 'DML', -
      schema_name => 'HR', -
      object_name => 'EMPLOYEES', -
      proc_name => 'DML_HANDLER');
```

Also, if an event matches multiple rules either because of the use of wildcards while specifying the rule or because of a specification of overlapping rules. For example, if you specify a rule for the SCHEMA\_DDL event for the HR.EMPLOYEES table, and a rule for the ALTER TABLE event for the HR.EMPLOYEES table, only one of the matching procedures will be invoked (alphabetically, by procedure). In the following code example, consider the following rules:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
      stmt => 'SCHEMA_DDL', -
      schema_name => 'HR', -
      object_name => 'EMPLOYEES', -
      proc_name => 'SCHEMA_DDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
      stmt => 'ALTER TABLE', -
      schema_name => 'HR', -
      object_name => 'EMPLOYEES', -
      proc_name => 'TABLE_ALTER_HANDLER');
```

On encountering an ALTER TABLE statement, the schema\_ddl\_handler procedure will be invoked because its name will be at the top of an alphabetically sorted list of procedures that are relevant to the statement. Collisions on a rule set because of a specification containing wildcard entries are resolved in a similar fashion. For example, the rules in the following example will result in the empddl\_handler procedure being invoked upon encountering the ALTER TABLE HR.EMPLOYEES ADD COLUMN RATING NUMBER statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
      stmt => 'ALTER TABLE', -
      schema_name => 'HR', -
      object_name => 'EMP%', -
```

```
proc_name => 'EMPDDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
  stmt => 'ALTER TABLE', -
  schema_name => 'HR', -
  object_name => 'EMPLOYEES', -
  proc_name => 'EMPLOYEE_DDL_HANDLER');
```

- Use the `SKIP` procedure with caution, particularly when skipping DDL statements. If a `CREATE TABLE` statement is skipped, for example, you must also specify other DDL statements that refer to that table in the `SKIP` procedure. Otherwise, the statements will fail and cause an exception. When this happens, SQL Apply stops running.
- Before calling the `SKIP` procedure, SQL Apply must be halted. Do this by issuing an `ALTER DATABASE STOP LOGICAL STANDBY APPLY` statement. Once all desired filters have been specified, issue an `ALTER DATABASE START LOGICAL STANDBY APPLY IMMEDIATE` statement to start SQL Apply using the new filter settings.
- See the `UNSKIP` procedure for information about reversing (undoing) the settings of the `SKIP` procedure.
- For `USER` statements, the `SCHEMA_NAME` parameter will be the user and specify '%' for the `OBJECT_NAME` parameter.
- If the `PROC_NAME` parameter is supplied, it must already exist in `DBA_PROCEEDURES` and it must execute with `DEFINER` rights. If the procedure is declared with `INVOKER` rights, the `ORA-1031: insufficient privileges` message will be returned.
- If the procedure returns a `REPLACEMENT` statement, the `REPLACEMENT` statement will be executed using the `SYSTEM` and `OBJECT` privileges of the owner of the procedure.
- The PL/SQL block of a `SKIP` procedure cannot contain transaction control statements (for example, `COMMIT`, `ROLLBACK`, `SAVEPOINT`, and `SET CONSTRAINT`) unless the block is declared to be an autonomous transaction.

#### Skip Statement Options

[Table 105-15](#) lists the supported values for the `stmt` parameter of the `SKIP` procedure. The left column of the table lists the keywords that may be used to identify the set of SQL statements to the right of the keyword. In addition, any of the SQL statements listed in the `sys.audit_actions` table (shown in the right column of [Table 105-15](#)) are also valid values. Note that keywords are generally defined by database object.

**Table 105-15 Supported Values for the `stmt` Parameter**

- <sup>1</sup> All directory objects are owned by SYS, but for the purpose of filtering them with a skip directive the schema should be specified as '%'
- <sup>2</sup> See *Oracle Data Guard Concepts and Administration* for information about supported packages.
- <sup>3</sup> Java schema objects (sources, classes, and resources) are considered the same as procedure for purposes of skipping (ignoring) SQL statements.

## Exceptions

| ORA-16236 | Logical standby metadata operation in progress.                                                                                                                                                                                                                                       |

## Examples

### Example 1. Skipping all DML and DDL changes made to a schema

The following example shows how to specify rules so that SQL Apply will skip both DDL and DML statements made to the HR schema.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(STMT => 'SCHEMA_DDL', -
    schema_name => 'HR', -
    object_name => '%', -
    proc_name => null);
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(STMT => 'DML', -
    schema_name => 'HR', -
    object_name => '%', -
    proc_name => null);
```

### Example 2. Creating a procedure to handle different file system organization

For example, if the file system organization in the logical standby database is different than that in the primary database, you can write a `SKIP` procedure to handle DDL statements with file specifications transparently. The following procedure can handle DDL statements as long as you follow a specific naming convention for the file specification string.

#### 1. Create the `SKIP` procedure to handle tablespace DDL statements:

```
CREATE OR REPLACE PROCEDURE sys.handle_tbs_ddl
IS
    l_old_stmt varchar2(4000);
    l_stmt_typ varchar2(40);
    l_schema   varchar2(30);
    l_name     varchar2(30);
    l_xidusn   number;
    l_xidslt   number;
    l_xidsqn   number;
    l_skip_action number;
    l_new_stmt varchar2(4000);

    -- read all information
    dbms_logstdby_context.get_context(name=>'STATEMENT',value=>l_old_stmt);
    dbms_logstdby_context.get_context(name=>'STATEMENT_TYPE',value=>l_stmt_type);
    dbms_logstdby_context.get_context(name=>'OWNER',value=>l_schema);
    dbms_logstdby_context.get_context(name=>'NAME',value=>l_name);
    dbms_logstdby_context.get_context(name=>'XIDUSN',value=>l_xidusn);
    dbms_logstdby_context.get_context(name=>'XIDSLT',value=>l_xidslt);
    dbms_logstdby_context.get_context(name=>'XIDSQN',value=>l_xidsqn);
    dbms_logstdby_context.get_context(name=>'CONTAINER_NAME',value=>l_conname);

    --
    -- All primary file specification that contains a directory
    -- /usr/orcl/primary/dbs
    -- should go to /usr/orcl/stdby directory specification

    BEGIN
        l_new_stmt := replace (l_old_stmt, '/usr/orcl/primary/dbs', '/usr/orcl/stdby');
        l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_REPLACE;
    EXCEPTION
        WHEN OTHERS THEN
            l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_ERROR;
            l_new_stmt := NULL;
    END;

    dbms_logstdby_context.set_context(name=>'new_statement', value => l_new_stmt);
    dbms_logstdby_context.set_context(name=>'SKIP_ACTION', value => l_skip_action);
END handle_tbs_ddl;
```

#### 2. Register the `SKIP` procedure with SQL Apply:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (stmt => 'TABLESPACE', -
    proc_name => 'SYS.HANDLE_TBS_DDL');
```

## Skipping Containers

To skip a container (either a PDB or the root), use the `CONTAINER` keyword. All SQL statements executed on the container, as well as any other actions taken on the container, are skipped.

You can skip a particular PDB within a CDB. For example, the following command skips the PDB named `PDB1`. The command must be executed at the root level:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(stmt => 'CONTAINER', object_name => 'PDB1');
```

As shown in the following example, you could also skip only the root of the CDB, but not any of the PDBs that exist under the root. The command must be executed at the root level:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(stmt => 'CONTAINER', object_name => 'CDB$ROOT');
```

### Note:

To create other skip rules for a container, create the rules from within the container. The container to which the rules will apply is automatically derived from the container in which the rules are created.

## 105.4.12 SKIP\_ERROR Procedure

The `SKIP_ERROR` procedure specifies the action to take when a logical standby database detects an error.

Upon encountering an error, the logical standby database uses the criteria contained in this procedure to determine a course of action. The default action when a match is found is to skip the error and continue with applying changes. However, if a procedure is supplied, then `SKIP_ERROR` can take other actions depending on the situation. It can do nothing, which causes SQL Apply to stop, or it can change the error message text and stop SQL Apply, or it can actually skip the error.

### Syntax

```
DBMS_LOGSTDBY.SKIP_ERROR (
    stmt                IN VARCHAR2,
    schema_name         IN VARCHAR2 DEFAULT NULL,
    object_name         IN VARCHAR2 DEFAULT NULL,
    proc_name           IN VARCHAR2 DEFAULT NULL,
    use_like            IN BOOLEAN  DEFAULT NULL,
    esc                 IN CHAR1    DEFAULT NULL);
```

### Parameters

**Table 105-17** SKIP\_ERROR Procedure Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stmt      | Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration because keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. <a href="#">Table 105-15</a> shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter. |

**Table 105-17 (Cont.) SKIP\_ERROR Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_name | The name of one or more schemas (wildcards are permitted) associated with the SQL statements identified by the <code>stmt</code> parameter. If not applicable, this value must be set to <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| object_name | The name of one or more objects (wildcards are permitted) associated with the SQL statements identified by the <code>stmt</code> . If not applicable, this value must be set to <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| proc_name   | <p>Name of a stored procedure to call when SQL Apply encounters an error and determines a particular statement matches the filter defined by the <code>stmt</code>, <code>schema_name</code>, and <code>object_name</code> parameters. Specify the procedure in the following format:</p> <pre>'"schema"."package"."procedure"'</pre> <p>This procedure returns an error message that directs SQL Apply to perform one of the following actions:</p> <ul style="list-style-type: none"> <li>• Silently skip the error and continue with SQL Apply</li> <li>• Replace the error message that would have been created with a custom one, and stop SQL Apply</li> <li>• Do nothing, causing SQL Apply to stop and the original error message to be logged</li> </ul> <p>The procedure registered with SQL Apply does not take any parameters. The context associated with <code>LSBY_APPLY_CONTEXT</code> can be used to retrieve all relevant information related to the error. See the <code>DBMS_LOGSTDBY_CONTEXT</code> package for a list of all parameters associated with <code>LSBY_APPLY_CONTEXT</code>.</p> <p>The parameters of interest for procedures registered with <code>SKIP_ERROR</code> are <code>CONTAINER_NAME</code>, <code>STATEMENT</code>, <code>STATEMENT_TYPE</code>, <code>SCHEMA</code>, <code>NAME</code>, <code>XIDUSN</code>, <code>XIDSLT</code>, <code>XIDSQN</code>, <code>ERROR</code> and <code>NEW_ERROR</code>.</p> |
| use_like    | Allows pattern matching to isolate the tables that you want to skip on the logical standby database. The <code>use_like</code> parameter matches a portion of one character value to another by searching the first value for the pattern specified by the second, and calculates strings using characters as defined by the input character set. This parameter follows the same rules for pattern matching described in <i>Oracle Database SQL Language Reference</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| esc         | Identifies an escape character (such as the characters <code>"%"</code> or <code>"_"</code> ) that you can use for pattern matching. If the escape character appears in the pattern before the character <code>"%"</code> or <code>"_"</code> then Oracle interprets this character literally in the pattern, rather than as a special pattern matching character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

#### Usage Notes

- A stored procedure provided to the `SKIP_ERROR` procedure is called when SQL Apply encounters an error that could shut down the application of redo logs to the standby database.
- Running this stored procedure affects the error being written in the `STATUS` column of the `DBA_LOGSTDBY_EVENTS` table. The `STATUS_CODE` column remains unchanged. If the stored procedure is to have no effect, that is, apply will be stopped, then the `NEW_ERROR` is written to the events table. To truly have no effect, set `NEW_ERROR` to `ERROR` in the procedure.
- If the stored procedure requires that a shutdown be avoided, then you must set `NEW_ERROR` to `NULL`.
- This procedure requires `DBA` privileges to execute.

- For **USER** statements, the **SCHEMA\_NAME** parameter will be the user and you should specify **'%'** for the **OBJECT\_NAME** parameter.
- If the **PROC\_NAME** parameter is specified, it must already exist in **DBA\_PROCEduRES** and it must execute with **DEFINERS** rights. If the procedure is declared with **INVOKERS** rights, the **ORA-1031: insufficient privileges** message will be returned.
- The **PL/SQL** block of a **SKIP\_ERROR** procedure cannot contain transaction control statements (for example: **COMMIT**, **ROLLBACK**, **SAVEPOINT**, and **SET CONSTRAINT**) unless the block is declared to be an autonomous transaction using the following syntax:

```
PRAGMA AUTONOMOUS_TRANSACTION
```

## Exceptions

**Table 105-18 SKIP\_ERROR Procedure Exceptions**

| Exception | Description                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01031 | Insufficient privileges: <ul style="list-style-type: none"> <li>• Procedure used <b>INVOKER</b> rights</li> <li>• Procedure needs <b>DBA</b> privileges</li> </ul> |
| ORA-16103 | Logical Standby apply must be stopped to allow this operation                                                                                                      |
| ORA-16104 | invalid Logical Standby option requested                                                                                                                           |
| ORA-16236 | Logical Standby metadata operation in progress                                                                                                                     |

### Example 1

The following example shows how to specify rules so that SQL Apply will skip any error raised from any **GRANT DDL** command.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR('GRANT')
```

### Example 2

To skip errors on **GRANT** statements on **SYS** or **HR** schemas, define a procedure **handle\_error\_ddl** and register it. In the following example, assume that **handle\_error\_ddl** is a free-standing procedure in the **SYS** schema.

#### 1. Create the error-handler procedure:

```
CREATE OR REPLACE PROCEDURE sys.handle_error_ddl
is
  l_stmt      VARCHAR2(4000);
  l_stmt_type VARCHAR2(40);
  l_schema    VARCHAR2(30);
  l_name      VARCHAR2(30);
  l_xidusn    NUMBER;
  l_xidslt    NUMBER;
  l_xidsqn    NUMBER;
  l_error     VARCHAR2(4000);
  l_conname   VARCHAR2(30);
  l_newerr    VARCHAR2(4000);

BEGIN
  dbms_logstdby_context.get_context(name=>'STATEMENT',value=>l_stmt);
  dbms_logstdby_context.get_context(name=>'STATEMENT_TYPE',value=>l_stmt_type);
  dbms_logstdby_context.get_context(name=>'SCHEMA',value=>l_schema);
  dbms_logstdby_context.get_context(name=>'NAME',value=>l_name);
```

```

dbms_logstdby_context.get_context(name=>'XIDUSN',value=>l_xidusn);
dbms_logstdby_context.get_context(name=>'XIDSLT',value=>l_xidslt);
dbms_logstdby_context.get_context(name=>'XIDSQN',value=>l_xidsqn);
dbms_logstdby_context.get_context(name=>'ERROR',value=>l_error);
dbms_logstdby_context.get_context(name=>'CONTAINER_NAME',value=>l_conname);

-- default error to what we already have
l_new_error := l_error;

-- Ignore any GRANT errors on SYS or HR schemas

IF INSTR(UPPER(l_stmt), 'GRANT') > 0
THEN
  IF l_schema is NULL
  OR (l_schema is NOT NULL AND
    (UPPER(l_schema) = 'SYS' OR
    UPPER(l_schema) = 'HR'))
  THEN
    l_new_error := NULL;
    -- record the fact that we just skipped an error on 'SYS' or 'HR' schemas
    -- code not shown here
  END IF;
END IF;

dbms_logstdby_context.set_context(name => 'NEW_ERROR', value => l_new_error);

END handle_error_ddl;
/

```

## 2. Register the error handler with SQL Apply:

```

SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR ( -
      statement => 'NON_SCHEMA_DDL', -
      schema_name => NULL, -
      object_name => NULL, -
      proc_name => 'SYS.HANDLE_ERROR_DDL');

```

## 105.4.13 SKIP\_TRANSACTION Procedure

This procedure provides a way to skip (ignore) applying transactions to the logical standby database. You can skip specific transactions by specifying transaction identification information.

### Syntax

```

DBMS_LOGSTDBY.SKIP_TRANSACTION (
  xidusn_p          IN NUMBER,
  xidslt_p          IN NUMBER,
  xidsqn_p          IN NUMBER,
  con_name_p        VARCHAR2  IN      DEFAULT NULL
);

```

### Parameters

**Table 105-19 SKIP\_TRANSACTION Procedure Parameters**

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| xidusn_p NUMBER | Transaction ID undo segment number of the transaction being skipped |
| xidslt_p NUMBER | Transaction ID slot number of the transaction being skipped         |

**Table 105-19 (Cont.) SKIP\_TRANSACTION Procedure Parameters**

| Parameter       | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| xidsqn_p NUMBER | Transaction ID sequence number of the transaction being skipped |
| con_name_p      | The transaction name.                                           |

### Usage Notes

If SQL Apply stops due to a particular transaction (for example, a DDL transaction), you can specify that transaction ID and then continue to apply. You can call this procedure multiple times for as many transactions as you want SQL Apply to ignore.

#### **WARNING:**

**SKIP\_TRANSACTION** is an inherently dangerous operation. Do not invoke this procedure unless you have examined the transaction in question through the **V\$LOGMNR\_CONTENTS** view and have taken compensating actions at the logical standby database. **SKIP\_TRANSACTION** is not the appropriate procedure to invoke to skip DML changes to a table.

To skip a DML failure, use a **SKIP** procedure, such as **SKIP('DML', 'MySchema', 'MyFailed Table')**. Using the **SKIP\_TRANSACTION** procedure for DML transactions may skip changes for other tables, thus logically corrupting them.

- This procedure requires **DBA** privileges to execute.
- Use the **DBA\_LOGSTDBY\_SKIP\_TRANSACTION** view to list the transactions that are going to be skipped by SQL Apply.

### Exceptions

**Table 105-20 SKIP\_TRANSACTION Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-01031 | Need DBA privileges                                           |
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |

### Examples

To skip a DDL transaction with (xidusn\_p, xidslt\_p, xidsqn\_p) of (1.13.1726) you can register a rule as shown in the following example:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_TRANSACTION (-
      xidusn_p => 1, xidslt_p => 13, xidsqn_p => 1726);
```

## 105.4.14 UNSKIP Procedure

Use the `UNSKIP` procedure to delete rules specified earlier with the `SKIP` procedure.

The parameters specified in the `UNSKIP` procedure must match exactly for it to delete an already-specified rule.

The `container_name` argument is valid only in a CDB.

### Syntax

```
DBMS_LOGSTDBY.UNSKIP (
    stmt                IN VARCHAR2,
    schema_name         IN VARCHAR2 DEFAULT NULL,
    object_name         IN VARCHAR2 DEFAULT NULL,
    container_name      IN VARCHAR2 DEFAULT NULL);
```

### Parameters

The parameter information for the `UNSKIP` procedure is the same as that described for the `SKIP` procedure. See [Table 105-14](#) for complete parameter information.

### Exceptions

**Table 105-21 UNSKIP Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-01031 | need DBA privileges to execute this procedure                 |
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |

### Usage Notes

#### WARNING:

If DML changes for a table have been skipped and not compensated for, you must follow the call to the `UNSKIP` procedure with a call to the `INstantiate_Table` procedure to synchronize this table with those maintained by SQL Apply.

- This procedure requires DBA privileges to execute.
- Wildcards passed in the `schema_name` or the `object_name` parameter are not expanded. The wildcard character is matched at the character level. Thus, you can delete only one specified rule by invoking the `UNSKIP` procedure, and you will need a distinct `UNSKIP` procedure call to delete each rule that was previously specified.

For example, assume you have specified the following two rules to skip applying DML statements to the `HR.EMPLOYEE` and `HR.EMPTEMP` tables:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML', -
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPLOYEE', -
    PROC_NAME => null);
```

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML', -
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPTEMP', -
    PROC_NAME => null);
```

In the following example, the wildcard in the `TABLE_NAME` parameter cannot be used to delete the rules that were specified:

```
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP (STMT => 'DML', -
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMP%');
```

In fact, this `UNSKIP` procedure matches neither of the rules, because the wildcard character in the `TABLE_NAME` parameter is not expanded. Instead, the wildcard character will be used in an exact match to find the corresponding `SKIP` rule.

## 105.4.15 UNSKIP\_ERROR Procedure

Use the `UNSKIP_ERROR` procedure to delete rules specified earlier with the `SKIP_ERROR` procedure.

The parameters specified in the `UNSKIP_ERROR` procedure must match exactly for the procedure to delete an already-specified rule.

The `container_name` argument is valid only in a CDB.

### Syntax

```
DBMS_LOGSTDBY.UNSKIP_ERROR (
    stmt                IN VARCHAR2,
    schema_name         IN VARCHAR2 DEFAULT NULL,
    object_name         IN VARCHAR2 DEFAULT NULL,
    container_name      IN VARCHAR2 DEFAULT NULL);
```

### Parameters

The parameter information for the `UNSKIP_ERROR` procedure is the same as that described for the `SKIP_ERROR` procedure. See [Table 105-17](#) for complete parameter information.

### Exceptions

**Table 105-22 UNSKIP\_ERROR Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-01031 | Need DBA privileges                                           |
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |

### Usage Notes

- This procedure requires `DBA` privileges to execute.
- Wildcards passed in the `schema_name` or the `object_name` parameters are not expanded. Instead, the wildcard character is treated as any other character and an exact match is made. Thus, you can delete only one specified rule by invoking the `UNSKIP_ERROR` procedure, and you need a distinct `UNSKIP_ERROR` procedure call to delete each rule that you previously specified.

For example, assume you have specified the following two rules to handle the HR.EMPLOYEE and HR.EMPTEMP tables:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPLOYEE', -
    PROC_NAME => 'hr_employee_handler');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPTEMP', -
    PROC_NAME => 'hr_tempemp_handler');
```

In this case, the following UNSKIP procedure cannot be used to delete the rules that you have specified:

```
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMP%');
```

In fact, the UNSKIP procedure will match neither of the rules, because the wildcard character in the OBJECT\_NAME parameter will not be expanded.

### Example

To remove a handler that was previously registered with SQL Apply from getting called on encountering an error, you can issue the following statement:

```
DBMS_LOGSTDBY.UNSKIP_ERROR ( -
    statement => 'NON_SCHEMA_DDL', -
    schema_name => NULL, -
    object_name => NULL);
```

## 105.4.16 UNSKIP\_TRANSACTION Procedure

Use the UNSKIP\_TRANSACTION procedure to delete rules specified earlier with the SKIP\_TRANSACTION procedure.

The parameters specified in the UNSKIP\_TRANSACTION procedure must match exactly for the procedure to delete an already-specified rule.

### Syntax

```
DBMS_LOGSTDBY.UNSKIP_TRANSACTION (
    xidusn_p          IN NUMBER,
    xidslt_p          IN NUMBER,
    xidsqn_p          IN NUMBER);
```

### Parameters

**Table 105-23 UNSKIP\_TRANSACTION Procedure Parameters**

| Parameter | Description                                                         |
|-----------|---------------------------------------------------------------------|
| XIDUSN    | Transaction ID undo segment number of the transaction being skipped |
| XIDSLT    | Transaction ID slot number of the transaction being skipped         |
| XIDSQN    | Transaction ID sequence number of the transaction being skipped     |

## Exceptions

**Table 105-24 UNSKIP\_TRANSACTION Procedure Exceptions**

| Exception | Description                                                   |
|-----------|---------------------------------------------------------------|
| ORA-01031 | need DBA privileges to execute this procedure                 |
| ORA-16103 | Logical Standby apply must be stopped to allow this operation |
| ORA-16104 | invalid Logical Standby option requested                      |

## Usage Notes

- This procedure requires DBA privileges to execute.
- Query the DBA\_LOGSTDBY\_SKIP\_TRANSACTION view to list the transactions that are going to be skipped by SQL Apply.

## Examples

To remove a rule that was originally specified to skip the application of a transaction with (XIDUSN, XIDSLT, XIDSQN) of (1.13.1726) issue the following statement:

```
SQL> DBMS_LOGSTDBY.UNSKIP_TRANSACTION (XIDUSN => 1, XIDSLT => 13, XIDSQN => 1726);
```

## DBMS\_LOGMNR\_D

The `DBMS_LOGMNR_D` package, one of a set of LogMiner packages, contains two subprograms: the `BUILD` procedure and the `SET_TABLESPACE` procedure.

- The `BUILD` procedure extracts the LogMiner data dictionary to either the redo log files or to a flat file. This information is saved in preparation for future analysis of redo log files using the LogMiner tool.
- The `SET_TABLESPACE` procedure re-creates all LogMiner tables in an alternate tablespace.

The **LogMiner data dictionary** consists of the memory data structures and the database tables that are used to store and retrieve information about objects and their versions. It is referred to as the **LogMiner dictionary** throughout the LogMiner documentation.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Summary of DBMS\\_LOGMNR\\_D Subprograms](#)

### See Also:

*Oracle Database Utilities* for information regarding LogMiner.

## 106.1 DBMS\_LOGMNR\_D Overview

LogMiner requires a dictionary to translate object IDs into object names when it returns redo data to you.

LogMiner gives you two options for supplying the dictionary:

- Using the online catalog
- Extracting a LogMiner dictionary to the redo log files
- Extracting a LogMiner dictionary to a flat file (for non-CDBs only)

### Note:

In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is desupported for PDBs in Oracle Database 19c, and desupported in later releases. With Oracle Database 19c and later releases, Oracle recommends that you call `DBMS_LOGMNR.START_LOGMNR`, and supply the system change number (SCN) or time range that you want to mine. The SCN or time range options of `START_LOGMNR` are enhanced to support mining of individual PDBs.

Use the `BUILD` procedure to extract the LogMiner dictionary to the redo log files or a flat file. If you want to specify the online catalog as the dictionary source, you do so when you start LogMiner with the `DBMS_LOGMNR.START_LOGMNR` package.

Use the `SET_TABLESPACE` procedure if you want LogMiner tables to use a tablespace other than the default `SYSAUX` tablespace.

**See Also:**

[DBMS\\_LOGMNR](#) for information on the package subprograms used in running a LogMiner session.

## 106.2 DBMS\_LOGMNR\_D Security Model

You must have the `EXECUTE_CATALOG_ROLE` role to use the `DBMS_LOGMNR_D` package.

## 106.3 Summary of DBMS\_LOGMNR\_D Subprograms

This table lists and briefly describes the `DBMS_LOGMNR_D` subprograms.

In a multitenant container database (CDB), some subprograms must be called from the root. There can be other differences as well. See the individual subprogram descriptions for details.

**Table 106-1 DBMS\_LOGMNR\_D Package Subprograms**

| Subprogram                               | Description                                                                          |
|------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">BUILD Procedure</a>          | Extracts the LogMiner dictionary to either a flat file or one or more redo log files |
| <a href="#">SET_TABLESPACE Procedure</a> | Re-creates all LogMiner tables in an alternate tablespace                            |

### 106.3.1 BUILD Procedure

This procedure extracts the LogMiner data dictionary to the redo log files.

The following considerations apply to a multitenant container database (CDB) environment.

- In a CDB environment, when you extract to the redo log files, the `BUILD` procedure must be called from the root database. The LogMiner data dictionary for the entire CDB is extracted to the redo log files.
- You cannot add or remove PDBs from a CDB while this procedure is running.

**Note:**

In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is desupported for PDBs in Oracle Database 19c, and desupported in later releases. With Oracle Database 19c and later releases, Oracle recommends that you call `DBMS_LOGMNR.DSTART_LOGMNR`, and supply the system change number (SCN) or time range that you want to mine. The SCN or time range options of `START_LOGMNR` are enhanced to support mining of individual PDBs.

**Syntax**

```
DBMS_LOGMNR_D.BUILD (  
    dictionary_filename IN VARCHAR2,  
    dictionary_location IN VARCHAR2,  
    options             IN NUMBER);
```

**Parameters****Table 106-2 BUILD Procedure Parameters**

| Parameter                        | Description                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>dictionary_filename</code> | Specifies the name of the LogMiner dictionary file.                                                          |
| <code>dictionary_location</code> | Specifies the directory object for the LogMiner dictionary file.                                             |
| <code>options</code>             | Specifies that the LogMiner dictionary is written to the redo log files ( <code>STORE_IN_REDO_LOGS</code> ). |

**Exceptions****Table 106-3 BUILD Procedure Exceptions**

| Exception | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01302 | <p>Dictionary build options are missing or incorrect.</p> <p>This error is returned under the following conditions:</p> <ul style="list-style-type: none"><li>• If the value of the <code>OPTIONS</code> parameter is not one of the supported values (<code>STORE_IN_REDO_LOGS</code>), or is not specified</li><li>• If the <code>STORE_IN_REDO_LOGS</code> option is not specified and neither the <code>dictionary_filename</code> nor the <code>dictionary_location</code> parameter is specified</li><li>• If the <code>STORE_IN_REDO_LOGS</code> option is specified and either the <code>dictionary_filename</code> or the <code>dictionary_location</code> parameter is specified</li></ul> |

**Table 106-3 (Cont.) BUILD Procedure Exceptions**

| Exception | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORA-01308 | Initialization parameter <code>UTL_FILE_DIR</code> is not set.                                                                                                                                                                                                                                                                                                                                                                                                 |
|           | <div> <b>Note:</b><br/>In earlier releases, you used the <code>UTL_FILE_DIR</code> initialization parameter to specify a directory location. However, as of Oracle Database 18c, the <code>UTL_FILE_DIR</code> initialization parameter is desupported. It is still supported for backward compatibility, but Oracle recommends that you instead use directory objects.</div> |
| ORA-01336 | Specified dictionary file cannot be opened.<br>This error is returned when the dictionary file is read-only.                                                                                                                                                                                                                                                                                                                                                   |
| ORA-01308 | Dictionary directory is not set.<br>This error is returned under the following conditions: <ul style="list-style-type: none"><li>• The specified value for the <code>dictionary_location</code> is not a directory object.</li><li>• The specified value for the <code>dictionary_location</code> is a directory object that is defined to be a file path that cannot be accessed.</li></ul>                                                                   |

### Usage Notes

- To extract the LogMiner dictionary to the redo log files, specify only the `STORE_IN_REDO_LOGS` option. The size of the LogMiner dictionary may cause it to be contained in multiple redo log files.  
The combinations of parameters used result in the following behavior:
  - If you do not specify any parameters, an error is returned.
  - If you do not specify a filename and location, but do specify the `STORE_IN_REDO_LOGS` option, the LogMiner dictionary is extracted to the redo log files.
  - If you specify a filename and location, as well as the `STORE_IN_REDO_LOGS` option, an error is returned.
- Ideally, the LogMiner dictionary file is created after all database dictionary changes have been made, and before the creation of any redo log files that you want to analyze. You can use LogMiner to dump the LogMiner dictionary to the redo log files, perform DDL operations, and dynamically apply the DDL changes to the LogMiner dictionary.
- The database must be open when you run the `DBMS_LOGMNR_D.BUILD` procedure.
- To extract a LogMiner dictionary file to the redo log files, the following conditions must be met:
  - Archivelog mode must be enabled in order to generate usable redo log files.
  - The `COMPATIBLE` parameter in the initialization parameter file must be set to 9.2.0 or higher.

- The database to which LogMiner is attached must be Oracle9i or later.

In addition, supplemental logging (at least the minimum level) should be enabled to ensure that you can take advantage of all the features that LogMiner offers.

### Examples

Example: Extracting the LogMiner Dictionary to the Redo Log Files

The following example extracts the LogMiner dictionary to the redo log files.

```
SQL> EXECUTE dbms_logmnr_d.build( -  
        options => dbms_logmnr_d.store_in_redo_logs);
```

## 106.3.2 SET\_TABLESPACE Procedure

This procedure moves LogMiner tables from the default `SYSAUX` tablespace to an alternate tablespace.

By default, all LogMiner tables are created to use the `SYSAUX` tablespace. However, it may be desirable to have LogMiner tables use an alternate tablespace. Use this procedure to move LogMiner tables to this alternate tablespace

In a CDB, only the LogMiner metadata in the local container is moved to the requested tablespace.

### Syntax

```
DBMS_LOGMNR_D.SET_TABLESPACE (  
    new_tablespace          IN VARCHAR2);
```

### Parameters

**Table 106-4 SET\_TABLESPACE Parameter**

| Parameter                   | Description                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>new_tablespace</code> | A string naming a preexisting tablespace. To move all LogMiner tables to employ this tablespace, supply this parameter. |

### Usage Notes

- Users upgrading from earlier versions of Oracle Database may find LogMiner tables in the `SYSTEM` tablespace. Oracle encourages such users to consider using the `SET_TABLESPACE` procedure to move the tables to the `SYSAUX` tablespace once they are confident that they will not be downgrading to an earlier version of Oracle Database.
- Users of this routine must supply an existing tablespace.

### Example: Using the DBMS\_LOGMNR\_D.SET\_TABLESPACE Procedure

The following example shows the creation of an alternate tablespace and execution of the `DBMS_LOGMNR_D.SET_TABLESPACE` procedure.

```
SQL> CREATE TABLESPACE logmnrt$ datafile '/usr/oracle/dbs/logmnrt$.f'  
        SIZE 25 M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;  
  
SQL> EXECUTE dbms_logmnr_d.set_tablespace('logmnrt$');
```

# DBMS\_LOGSTDBY\_CONTEXT

As of Oracle Database 12c release 1 (12.1), SQL Apply processes have access to a context namespace called `LSBY_APPLY_CONTEXT`. You can use the procedures provided in the `DBMS_LOGSTDBY_CONTEXT` package to set and retrieve various parameters associated with `LSBY_APPLY_CONTEXT`. This is useful when writing skip procedures that are registered with SQL Apply using the `DBMS_LOGSTDBY.SKIP` and `DBMS_LOGSTDBY.SKIP_ERROR` procedures.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Summary of DBMS\\_LOGSTDBY\\_CONTEXT Subprograms](#)

## See Also:

*Oracle Data Guard Concepts and Administration* for more information about SQL Apply and logical standby databases

## 107.1 DBMS\_LOGSTDBY\_CONTEXT Overview

SQL Apply processes have access to a context namespace called `LSBY_APPLY_CONTEXT`.

The following table lists the predefined parameters associated with `LSBY_APPLY_CONTEXT` that you can set and retrieve by using the procedures provided in the `DBMS_LOGSTDBY_CONTEXT` package. The ability to set and retrieve the parameters in this way is useful when writing skip procedures that are registered with SQL Apply using the `DBMS_LOGSTDBY.SKIP` and `DBMS_LOGSTDBY.SKIP_ERROR` procedures.

**Table 107-1** Predefined Parameters of Namespace `LSBY_APPLY_CONTEXT`

| Parameter                   | Description                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------|
| <code>STATEMENT</code>      | First 4000 bytes of the statement that the Apply process is processing.                |
| <code>STATEMENT_TYPE</code> | See <a href="#">Table 105-15</a> for a list of various statement types.                |
| <code>PACKAGE_SCHEMA</code> | Schema that owns the PL/SQL package being processed (if applicable).                   |
| <code>PACKAGE_NAME</code>   | Name of the PL/SQL package being processed (if applicable).                            |
| <code>PROCEDURE_NAME</code> | Name of the PL/SQL procedure being processed (if applicable).                          |
| <code>CURRENT_SCHEMA</code> | Current schema in effect when the DDL or PL/SQL procedure was executed at the primary. |
| <code>XIDUSN</code>         | XIDUSN of the transaction at the primary database.                                     |
| <code>XIDSLT</code>         | XIDSLT of the transaction at the primary database.                                     |

**Table 107-1 (Cont.) Predefined Parameters of Namespace LBY\_APPLY\_CONTEXT**

| Parameter      | Description                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| XIDSQLN        | XIDSQLN of the transaction at the primary database.                                                                                       |
| SCHEMA         | Schema that owns the object being processed by SQL Apply (in the case of DML or DDL operations).                                          |
| NAME           | Object name being processed by SQL Apply (in case of DML or DDL operations).                                                              |
| CONTAINER_NAME | Container where the target object or the PL/SQL procedure resides (in the case of a multitenant container database (CDB)).                |
| ERROR          | Text of the original error encountered by the SQL Apply process (if applicable).                                                          |
| NEW_ERROR      | Text of the new error to be raised by the SQL Apply process (if applicable, See the DBMS_LOGSTDBY <a href="#">SKIP_ERROR Procedure</a> ). |
| NEW_STMT       | Text of the replacement statement that SQL Apply must execute (If applicable, See the DBMS_LOGSTDBY <a href="#">SKIP Procedure</a> ).     |
| SKIP_ACTION    | The skip action to be performed by SQL Apply (See the DBMS_LOGSTDBY <a href="#">SKIP Procedure</a> ).                                     |

## 107.2 DBMS\_LOGSTDBY\_CONTEXT Security Model

The security model for the DBMS\_LOGSTDBY\_CONTEXT package is the same as for the DBMS\_LOGSTDBY package.

**See Also:**

[DBMS\\_LOGSTDBY](#)

## 107.3 Summary of DBMS\_LOGSTDBY\_CONTEXT Subprograms

This table lists and briefly describes the DBMS\_LOGSTDBY\_CONTEXT package subprograms.

**Table 107-2 DBMS\_LOGSTDBY\_CONTEXT Package Subprograms**

| Subprogram                                  | Description                                                         |
|---------------------------------------------|---------------------------------------------------------------------|
| <a href="#">CLEAR_ALL_CONTEXT Procedure</a> | Clears all parameters contained within namespace LBY_APPLY_CONTEXT. |
| <a href="#">CLEAR_CONTEXT Procedure</a>     | Clears the specific parameter.                                      |
| <a href="#">GET_CONTEXT Procedure</a>       | Retrieves the value for the specified parameter.                    |
| <a href="#">SET_CONTEXT Procedure</a>       | Sets the named parameter with the specified value.                  |

## 107.3.1 CLEAR\_ALL\_CONTEXT Procedure

This procedure clears all parameters contained within namespace `LSBY_APPLY_CONTEXT`.

### Syntax

```
DBMS_LOGSTDBY_CONTEXT.CLEAR_ALL_CONTEXT;
```

### Parameters

None

## 107.3.2 CLEAR\_CONTEXT Procedure

This procedure clears the specific parameter.

### Syntax

```
DBMS_LOGSTDBY_CONTEXT.CLEAR_CONTEXT (
    name          IN VARCHAR2);
```

### Parameters

**Table 107-3** *CLEAR\_CONTEXT Procedure Parameters*

| Parameter | Description                          |
|-----------|--------------------------------------|
| name      | Name of the parameter to be cleared. |

## 107.3.3 GET\_CONTEXT Procedure

This procedure retrieves the value for the specified parameter.

### Syntax

```
DBMS_LOGSTDBY_CONTEXT.GET_CONTEXT (
    name          IN VARCHAR2,
    value         OUT VARCHAR2);
```

### Parameters

**Table 107-4** *GET\_CONTEXT Procedure Parameters*

| Parameter | Description                            |
|-----------|----------------------------------------|
| name      | Name of the parameter.                 |
| value     | The value retrieved for the parameter. |

## 107.3.4 SET\_CONTEXT Procedure

This procedure sets the named parameter with the specified value.

### Syntax

```
DBMS_LOGSTDBY_CONTEXT.SET_CONTEXT (
    name          IN VARCHAR2
    value          IN VARCHAR2);
```

### Parameters

**Table 107-5** *SET\_CONTEXT Procedure Parameters*

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| name      | Name of the parameter to be set.                 |
| value     | Value to be assigned to the parameter being set. |

# DBMS\_MEMOPTIMIZE

The `DBMS_MEMOPTIMIZE` package provides the interface for managing the Memoptimized Rowstore data buffered in the large pool and the memoptimize pool.

This chapter contains the following topics:

- [DBMS\\_MEMOPTIMIZE Overview](#)
- [Summary of DBMS\\_MEMOPTIMIZE Subprograms](#)

## 108.1 DBMS\_MEMOPTIMIZE Overview

The `DBMS_MEMOPTIMIZE` package provides the interface for managing Memoptimized Rowstore data buffered in the large pool and the memoptimize pool.

The Memoptimized Rowstore provides the following functionality:

- **Fast Ingest**  
Fast ingest optimizes the processing of high-frequency, single-row data inserts. Fast ingest uses the large pool in the SGA for buffering the inserts before writing them to disk.
- **Fast Lookup**  
Fast lookup enables fast retrieval of data for high-frequency queries. Fast lookup uses a separate memory area in the SGA called the *memoptimize pool* for buffering data queried from tables.

The `DBMS_MEMOPTIMIZE` package provides the following operations related to the Memoptimized Rowstore:

- **Fast ingest operations:**
  - Provide the low high-water mark (low HWM) of the sequence numbers of rows that have been successfully written from the large pool to disk across all the sessions.
  - Provide the high-water mark (HWM) sequence number of the row that has been written to the large pool for the current session.
  - Flush all the fast ingest data from the large pool to disk for the current session.
- **Fast lookup operations:**
  - Remove data for a table from the memoptimize pool.
  - Populate data for a table in the memoptimize pool.

## 108.2 Summary of DBMS\_MEMOPTIMIZE Subprograms

This table lists the `DBMS_MEMOPTIMIZE` subprograms and briefly describes them.

**Table 108-1 DBMS\_MEMOPTIMIZE Package Subprograms Related to Fast Ingest**

| Procedure                                    | Description                                                                                                                                             |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GET_APPLY_HWM_SEQID Function</a> | Returns the low high-water mark (low HWM) of the sequence numbers of rows that have been successfully written to disk globally across all the sessions. |
| <a href="#">GET_WRITE_HWM_SEQID Function</a> | Returns the high-water mark (HWM) sequence number of the row that has been written to the large pool for the current session.                           |
| <a href="#">WRITE_END Procedure</a>          | Flushes all the fast ingest data from the large pool to disk for the current session.                                                                   |

**Table 108-2 DBMS\_MEMOPTIMIZE Package Subprograms Related to Fast Lookup**

| Procedure                             | Description                                         |
|---------------------------------------|-----------------------------------------------------|
| <a href="#">DROP_OBJECT Procedure</a> | Removes data for a table from the memoptimize pool. |
| <a href="#">POPULATE Procedure</a>    | Populates data for a table in the memoptimize pool. |

## 108.2.1 DROP\_OBJECT Procedure

This procedure removes data for a table from the memoptimize pool.

### Syntax

```
DBMS_MEMOPTIMIZE.DROP_OBJECT (  
    schema_name      IN VARCHAR2,  
    table_name       IN VARCHAR2,  
    partition_name    IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 108-3 DROP\_OBJECT Procedure Parameters**

| Parameter                   | Description                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schema_name</code>    | Name of the schema.                                                                                                                                        |
| <code>table_name</code>     | Name of the table for which the data needs to be removed from the memoptimize pool.                                                                        |
| <code>partition_name</code> | Name of the table partition for which the data needs to be removed from the memoptimize pool. This is an optional parameter and its default value is NULL. |

## 108.2.2 GET\_APPLY\_HWM\_SEQID Function

This function returns the low high-water mark (low HWM) of sequence numbers of the records that have been successfully written to disk across all the sessions.

### Syntax

```
DBMS_MEMOPTIMIZE.GET_APPLY_HWM_SEQID  
RETURN number;
```

### Return Value

Returns the low high-water mark (low HWM) of sequence numbers of the records that have been successfully written to disk across all the sessions.

## 108.2.3 GET\_WRITE\_HWM\_SEQID Function

This function returns the high-water mark (HWM) sequence number of the record that has been written to the large pool for the current session.

### Syntax

```
DBMS_MEMOPTIMIZE.GET_WRITE_HWM_SEQID  
RETURN number;
```

### Return Value

Returns the high-water mark (HWM) sequence number of the record that has been written to the large pool for the current session.

## 108.2.4 POPULATE Procedure

This procedure populates the data for a table in the memoptimize pool.

### Syntax

```
DBMS_MEMOPTIMIZE.POPULATE (  
    schema_name      IN VARCHAR2,  
    table_name       IN VARCHAR2,  
    partition_name   IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 108-4 POPULATE Procedure Parameters**

| Parameter   | Description                                                                         |
|-------------|-------------------------------------------------------------------------------------|
| schema_name | Name of the schema.                                                                 |
| table_name  | Name of the table for which the data needs to be populated in the memoptimize pool. |

**Table 108-4 (Cont.) POPULATE Procedure Parameters**

| Parameter                   | Description                                                                                                                                                   |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>partition_name</code> | Name of the table partition for which the data needs to be populated in the memoptimize pool.<br>This is an optional parameter and its default value is NULL. |

## 108.2.5 WRITE\_END Procedure

This procedure flushes all the fast ingest data from the large pool to disk for the current session.

### Syntax

```
DBMS_MEMOPTIMIZE.WRITE_END;
```

# DBMS\_MEMOPTIMIZE\_ADMIN

The `DBMS_MEMOPTIMIZE_ADMIN` package provides the interface for flushing the Memoptimized Rowstore data buffered in the large pool to disk.

This chapter contains the following topics:

- [DBMS\\_MEMOPTIMIZE\\_ADMIN Overview](#)
- [Summary of DBMS\\_MEMOPTIMIZE\\_ADMIN Subprograms](#)

## 109.1 DBMS\_MEMOPTIMIZE\_ADMIN Overview

The `DBMS_MEMOPTIMIZE_ADMIN` package provides the interface for flushing the Memoptimized Rowstore data that is buffered in the large pool to disk.

The Memoptimized Rowstore provides the following functionality:

- **Fast Ingest**  
Fast ingest optimizes the processing of high-frequency, single-row data inserts. Fast ingest uses the large pool in the SGA for buffering the inserts before writing them to disk.
- **Fast Lookup**  
Fast lookup enables fast retrieval of data for high-frequency queries. Fast lookup uses a separate memory area in the SGA called the *memoptimize pool* for buffering the data queried from tables.

The `DBMS_MEMOPTIMIZE_ADMIN` package provides the following operation related to fast ingest of the Memoptimized Rowstore:

- Flush fast ingest data from the large pool to disk for all sessions.

## 109.2 Summary of DBMS\_MEMOPTIMIZE\_ADMIN Subprograms

This table lists the `DBMS_MEMOPTIMIZE_ADMIN` subprograms and briefly describes them.

**Table 109-1 DBMS\_MEMOPTIMIZE\_ADMIN Package Subprograms**

| Procedure                              | Description                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <a href="#">WRITES_FLUSH Procedure</a> | Flushes all the fast ingest data of the Memoptimize Rowstore from the large pool to disk for all the sessions. |

## 109.2.1 WRITES\_FLUSH Procedure

This procedure flushes all the fast ingest data of the Memoptimized Rowstore from the large pool to disk for all the sessions.

### Syntax

```
DBMS_MEMOPTIMIZE_ADMIN.WRITES_FLUSH;
```

# DBMS\_METADATA

The `DBMS_METADATA` package provides a way for you to retrieve metadata from the database dictionary as XML or creation DDL and to submit the XML to re-create the object.

## See Also:

*Oracle Database Utilities* for more information and for examples of using the `DBMS_METADATA` package.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Rules and Limits](#)
- [Data Structures - Object and Table Types](#)
- [Subprogram Groupings](#)
  - [Subprograms for Retrieving Multiple Objects From the Database](#)
  - [Subprograms for Submitting XML to the Database](#)
- [Summary of All DBMS\\_METADATA Subprograms](#)

## 110.1 DBMS\_METADATA Overview

You can use the `DBMS_METADATA` package to retrieve metadata and to submit XML.

### Retrieving Metadata

If you are retrieving metadata, you can specify:

- The kind of object to be retrieved. This can be either a particular object type (such as a table, index, or procedure) or a heterogeneous collection of object types that form a logical unit (such as a database export or schema export).
- Optional selection criteria, such as owner or name.
- Parse items (attributes of the returned objects to be parsed and returned separately).
- Optional transformations on the output, implemented by XSLT (Extensible Stylesheet Language Transformation) scripts. By default the output is represented in XML, but you can specify transformations (into SQL DDL, for example), which are implemented by XSLT stylesheets stored in the database or externally.

`DBMS_METADATA` provides the following retrieval interfaces:

- **For programmatic use:** `OPEN`, `SET_FILTER`, `SET_COUNT`, `GET_QUERY`, `SET_PARSE_ITEM`, `ADD_TRANSFORM`, `SET_TRANSFORM_PARAM`, `SET_REMAP_PARAM`, `FETCH_xxx`, and `CLOSE` retrieve multiple objects.

- For use in SQL queries and for browsing: `GET_XML`, `GET_DDL` and `GET_SXML` return metadata for a single named object. The `GET_DEPENDENT_XML`, `GET_DEPENDENT_DDL`, `GET_GRANTED_XML`, and `GET_GRANTED_DDL` interfaces return metadata for one or more dependent or granted objects. These procedures do not support heterogeneous object types.

### Submitting XML

If you are submitting XML, you specify:

- The type of object
- Optional transform parameters to modify the object (for example, changing the object's owner)
- Parse items (attributes of the submitted objects to be parsed and submitted separately)
- Whether to execute the operation or simply return the generated DDL

DBMS\_METADATA provides a programmatic interface for submission of XML. It is comprised of the following procedures: `OPENW`, `ADD_TRANSFORM`, `SET_TRANSFORM_PARAM`, `SET_REMAP_PARAM`, `SET_PARSE_ITEM`, `CONVERT`, `PUT`, and `CLOSE`.

## 110.2 DBMS\_METADATA Security Model

The DBMS\_METADATA package considers a privileged user to be one who is connected as user `SYS` or who has the `SELECT_CATALOG_ROLE` role.

The object views of the Oracle metadata model implement security as follows:

- Nonprivileged users can see the metadata of only their own objects.
- Nonprivileged users can also retrieve public synonyms, system privileges granted to them, and object privileges granted to them or by them to others. This also includes privileges granted to `PUBLIC`.
- If callers request objects they are not privileged to retrieve, no exception is raised; the object is simply not retrieved.
- If nonprivileged users are granted some form of access to an object in someone else's schema, they will be able to retrieve the grant specification through the Metadata API, but not the object's actual metadata.
- In stored procedures, functions, and definers-rights packages, roles (such as `SELECT_CATALOG_ROLE`) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker's possession of `SELECT_CATALOG_ROLE`), you must make the program invokers-rights.
- For all objects that have passwords, except database links (for example, users and roles), the following rules apply:
  - A user who has the `SELECT_CATALOG_ROLE` can see all metadata for an object except the passwords for that object.
  - The `SYS` user, users who have the `EXP_FULL_DATABASE` role, and users who own an object can see all metadata for that object, including passwords.
- For database links the password is never displayed. For security reasons Oracle restricts visibility of the password value to `SYS` users who query the `link$.passwordx` column directly. Instead of the password, DBMS\_METADATA returns the following invalid syntax:

```
IDENTIFIED BY VALUES ':1'
```

A user who knows the password of the database link can manually replace the :1 with the password.

## 110.3 Rules and Limits

In an Oracle Shared Server (OSS) environment, the `DBMS_METADATA` package must disable session migration and connection pooling.

This results in any shared server process that is serving a session running the package to effectively become a default, dedicated server for the life of the session. You should ensure that sufficient shared servers are configured when the package is used and that the number of servers is not artificially limited by too small a value for the `MAX_SHARED_SERVERS` initialization parameter.

## 110.4 DBMS\_METADATA Data Structures - Object and Table Types

The `DBMS_METADATA` package defines, in the `SYS` schema, the `OBJECT` and `TABLE` types shown in this code.

```
CREATE TYPE sys.ku$_parsed_item AS OBJECT (
    item          VARCHAR2(30),
    value         VARCHAR2(4000),
    object_row    NUMBER )
/

CREATE PUBLIC SYNONYM ku$_parsed_item FOR sys.ku$_parsed_item;

CREATE TYPE sys.ku$_parsed_items IS TABLE OF sys.ku$_parsed_item
/

CREATE PUBLIC SYNONYM ku$_parsed_items FOR sys.ku$_parsed_items;

CREATE TYPE sys.ku$_ddl AS OBJECT (
    ddlText      CLOB,
    parsedItems  sys.ku$_parsed_items )
/

CREATE PUBLIC SYNONYM ku$_ddl FOR sys.ku$_ddl;

CREATE TYPE sys.ku$_ddls IS TABLE OF sys.ku$_ddl
/

CREATE PUBLIC SYNONYM ku$_ddls FOR sys.ku$_ddls;

CREATE TYPE sys.ku$_multi_ddl AS OBJECT (
    object_row   NUMBER,
    ddls         sys.ku$_ddls )
/

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddl FOR sys.ku$_multi_ddl;

CREATE TYPE sys.ku$_multi_ddls IS TABLE OF sys.ku$_multi_ddl;
/

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddls FOR
```

```

sys.ku$_multi_ddls;

CREATE TYPE sys.ku$_ErrorLine IS OBJECT (
    errorNumber    NUMBER,
    errorText      VARCHAR2(2000) )
/

CREATE PUBLIC SYNONYM ku$_ErrorLine FOR sys.ku$_ErrorLine;

CREATE TYPE sys.ku$_ErrorLines IS TABLE OF sys.ku$_ErrorLine
/
CREATE PUBLIC SYNONYM ku$ErrorLines FOR sys.ku$_ErrorLines;

CREATE TYPE sys.ku$_SubmitResult AS OBJECT (
    ddl            sys.ku$_ddl,
    errorLines     sys.ku$_ErrorLines );
/

CREATE TYPE sys.ku$_SubmitResults IS TABLE OF sys.ku$_SubmitResult
/

CREATE PUBLIC SYNONYM ku$_SubmitResults FOR sys.ku$_SubmitResults;

```

**Note:**

The maximum size of the `VARCHAR2`, `NVARCHAR2`, and `RAW` datatypes has been increased to 32 KB when the `COMPATIBLE` initialization parameter is set to 12.0 and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`. The `DBMS_METADATA` package supports this increased size unless the version of the metadata is earlier than Oracle Database 12c Release 1 (12.1).

## 110.5 DBMS\_METADATA Subprogram Groupings

The `DBMS_METADATA` subprograms retrieve objects from, and submit XML to, a database. Some subprograms are used for both activities, while others are used only for retrieval or only for submission.

- [Table 110-1](#) provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to retrieve multiple objects from a database.
- [Table 110-2](#) provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to submit XML metadata to a database.

### 110.5.1 DBMS\_METADATA Subprograms for Retrieving Multiple Objects From the Database

`DBMS_METADATA` uses these subprograms used for retrieving multiple objects from the database.

**Table 110-1 DBMS\_METADATA Subprograms for Retrieving Multiple Objects**

| Subprogram                             | Description                                                                                                  |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_TRANSFORM Function</a> | Specifies a transform that <code>FETCH_XXX</code> applies to the XML representation of the retrieved objects |

**Table 110-1 (Cont.) DBMS\_METADATA Subprograms for Retrieving Multiple Objects**

| Subprogram                                                         | Description                                                                                                                                                                    |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CLOSE Procedure</a> <a href="#">CLOSE Procedure</a>    | Invalidates the handle returned by <code>OPEN</code> and cleans up the associated state                                                                                        |
| <a href="#">FETCH_xxx Functions and Procedures</a>                 | Returns metadata for objects meeting the criteria established by <code>OPEN</code> , <code>SET_FILTER</code> , <code>SET_COUNT</code> , <code>ADD_TRANSFORM</code> , and so on |
| <a href="#">GET_QUERY Function</a>                                 | Returns the text of the queries that are used by <code>FETCH_xxx</code>                                                                                                        |
| <a href="#">GET_xxx Functions</a>                                  | Fetches the metadata for a specified object as XML, SXML, or DDL, using only a single call                                                                                     |
| <a href="#">OPEN Function</a>                                      | Specifies the type of object to be retrieved, the version of its metadata, and the object model                                                                                |
| <a href="#">SET_COUNT Procedure</a>                                | Specifies the maximum number of objects to be retrieved in a single <code>FETCH_xxx</code> call                                                                                |
| <a href="#">SET_FILTER Procedure</a>                               | Specifies restrictions on the objects to be retrieved, for example, the object name or schema                                                                                  |
| <a href="#">SET_PARSE_ITEM Procedure</a>                           | Enables output parsing by specifying an object attribute to be parsed and returned                                                                                             |
| <a href="#">SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures</a> | Specifies parameters to the XSLT stylesheets identified by <code>transform_handle</code>                                                                                       |

## 110.5.2 DBMS\_METADATA Subprograms for Submitting XML to the Database

DBMS\_METADATA uses these subprograms for submitting XML to the database.

**Table 110-2 DBMS\_METADATA Subprograms for Submitting XML**

| Subprogram                                                         | Description                                                                                                                                 |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_TRANSFORM Function</a>                             | Specifies a transform for the XML documents                                                                                                 |
| <a href="#">CLOSE Procedure</a> <a href="#">CLOSE Procedure</a>    | Closes the context opened with <code>OPENW</code>                                                                                           |
| <a href="#">CONVERT Functions and Procedures</a>                   | Converts an XML document to DDL                                                                                                             |
| <a href="#">OPENW Function</a>                                     | Opens a write context                                                                                                                       |
| <a href="#">PUT Function</a>                                       | Submits an XML document to the database                                                                                                     |
| <a href="#">SET_PARSE_ITEM Procedure</a>                           | Specifies an object attribute to be parsed                                                                                                  |

## 110.6 Summary of All DBMS\_METADATA Subprograms

This table lists the DBMS\_METADATA subprograms and briefly describes them.

**Table 110-3 DBMS\_METADATA Package Subprograms**

| Subprogram                                                         | Description                                                                                                                                                                    |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_TRANSFORM Function</a>                             | Specifies a transform that <code>FETCH_xxx</code> applies to the XML representation of the retrieved objects                                                                   |
| <a href="#">CLOSE Procedure</a>                                    | Invalidates the handle returned by <code>OPEN</code> and cleans up the associated state                                                                                        |
| <a href="#">CONVERT Functions and Procedures</a>                   | Converts an XML document to DDL                                                                                                                                                |
| <a href="#">FETCH_xxx Functions and Procedures</a>                 | Returns metadata for objects meeting the criteria established by <code>OPEN</code> , <code>SET_FILTER</code> , <code>SET_COUNT</code> , <code>ADD_TRANSFORM</code> , and so on |
| <a href="#">GET_xxx Functions</a>                                  | Fetches the metadata for a specified object as XML, SXML, or DDL, using only a single call                                                                                     |
| <a href="#">GET_QUERY Function</a>                                 | Returns the text of the queries that are used by <code>FETCH_xxx</code>                                                                                                        |
| <a href="#">OPEN Function</a>                                      | Specifies the type of object to be retrieved, the version of its metadata, and the object model                                                                                |
| <a href="#">OPENW Function</a>                                     | Opens a write context                                                                                                                                                          |
| <a href="#">PUT Function</a>                                       | Submits an XML document to the database                                                                                                                                        |
| <a href="#">SET_COUNT Procedure</a>                                | Specifies the maximum number of objects to be retrieved in a single <code>FETCH_xxx</code> call                                                                                |
| <a href="#">SET_FILTER Procedure</a>                               | Specifies restrictions on the objects to be retrieved, for example, the object name or schema                                                                                  |
| <a href="#">SET_PARSE_ITEM Procedure</a>                           | Enables output parsing by specifying an object attribute to be parsed and returned                                                                                             |
| <a href="#">SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures</a> | Specifies parameters to the XSLT stylesheets identified by <code>transform_handle</code>                                                                                       |

## 110.6.1 ADD\_TRANSFORM Function

The `DBMS_METADATA.ADD_TRANSFORM` function is used for both retrieval and submission.

- When this procedure is used to retrieve objects, it specifies a transform that `FETCH_xxx` applies to the XML representation of the retrieved objects.
- When used to submit objects, it specifies a transform that `CONVERT` or `PUT` applies to the XML representation of the submitted objects. It is possible to add more than one transform.

### See Also:

- [Subprograms for Retrieving Multiple Objects From the Database](#)
- [Subprograms for Submitting XML to the Database](#)

### Syntax

```
DBMS_METADATA.ADD_TRANSFORM (
    handle          IN NUMBER,
```

```

name          IN VARCHAR2,
encoding      IN VARCHAR2 DEFAULT NULL,
object_type   IN VARCHAR2 DEFAULT NULL)
RETURN NUMBER;

```

## Parameters

**Table 110-4 ADD\_TRANSFORM Function Parameters**

| Parameters  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle returned from <code>OPEN</code> when this transform is used to retrieve objects. Or the handle returned from <code>OPENW</code> when this transform is used in the submission of XML metadata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| name        | <p>The name of the transform. The name can be an internal keyword like <code>DDL</code> to use internally stored stylesheets. If the name contains a colon, it is interpreted as <code>directory_object_name:file_name</code> of a user-supplied Extensible Stylesheet Language Transformation (XSLT) script. Otherwise, name designates a transform implemented by <code>DBMS_METADATA</code>.</p> <p>See <a href="#">Table 110-5</a> for descriptions of available transforms.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| encoding    | The name of the Globalization Support character set in which the stylesheet pointed to by name is encoded. This is only valid if name is a URL. If left <code>NULL</code> and the URL is external to the database, UTF-8 encoding is assumed. If left <code>NULL</code> and the URL is internal to the database (that is, it begins with <code>/oradb/</code> ), then the encoding is assumed to be the database character set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| object_type | <p>The definition of this parameter depends upon whether you are retrieving objects or submitting XML metadata.</p> <ol style="list-style-type: none"> <li>When you use <code>ADD_TRANSFORM</code> to retrieve objects, the following definition of <code>object_type</code> applies: <p>Designates the object type to which the transform applies. (Note that this is an object type name, not a path name.) By default the transform applies to the object type of the <code>OPEN</code> handle. When the <code>OPEN</code> handle designates a heterogeneous object type, the following behavior can occur:</p> <ul style="list-style-type: none"> <li>if <code>object_type</code> is omitted, the transform applies to all object types within the heterogeneous collection</li> <li>if <code>object_type</code> is specified, the transform only applies to that specific object type within the collection</li> </ul> <p>If you omit this parameter you can add the DDL transform to all objects in a heterogeneous collection with a single call. If you supply this parameter, you can add a transform for a specific object type.</p> </li> <li>When you use <code>ADD_TRANSFORM</code> in the submission of XML metadata, this parameter is the object type to which the transform applies. By default, it is the object type of the <code>OPENW</code> handle. Because the <code>OPENW</code> handle cannot designate a heterogeneous object type, the caller would normally leave this parameter <code>NULL</code> in the <code>ADD_TRANSFORM</code> calls.</li> </ol> |

The following table describes the transforms available on the `ADD_TRANSFORM` function.

Because new transforms are occasionally added, you might want to query the `DBMS_METADATA_TRANSFORMS` view to see all valid Oracle-supplied transforms for specific object types.

**Table 110-5 Transforms Available on ADD\_TRANSFORM Function**

| Object Type | Transform Name | Input Doc Type           | Output Doc Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Subset      | ALTERXML       | SXML difference document | ALTER_XML       | <p>Generate ALTER_XML from SXML difference document. (See the <code>DBMS_METADATA_DIFF</code> PL/SQL package for more information about SXML difference format.)</p> <p>The following parameters are valid for the ALTERXML transform:</p> <ul style="list-style-type: none"> <li>• <code>XPATH</code> - The XPATH of the object being altered</li> <li>• <code>NAME</code> - Name of the object being altered</li> <li>• <code>ALTERABLE</code> - Affirms that the object can be altered. If the object cannot be altered, a <code>NOT_ALTERABLE</code> element is inserted whose value indicates the reason.</li> <li>• <code>CLAUSE_TYPE</code> - The type of clause (for example, <code>ADD_COLUMN</code>)</li> <li>• <code>COLUMN_ATTRIBUTE</code> - The attribute being modified</li> <li>• <code>CONSTRAINT_TYPE</code> - The type of constraint (for example, <code>UNIQUE</code> or <code>PRIMARY</code>)</li> </ul> |
| Subset      | ALTERDDL       | ALTER_XML                | ALTER_DDL       | Convert ALTER_XML to ALTER_DDL                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Return Values

The opaque handle that is returned is used as input to `SET_TRANSFORM_PARAM` and `SET_REMAP_PARAM`. Note that this handle is different from the handle returned by `OPEN` or `OPENW`; it refers to the transform, not the set of objects to be retrieved.

### Usage Notes

- With no transforms added, objects are returned by default as XML documents. You call `ADD_TRANSFORM` to specify the XSLT stylesheets to be used to transform the returned XML documents.

- You can call `ADD_TRANSFORM` more than once to apply multiple transforms to XML documents. The transforms are applied in the order in which they were specified, the output of the first transform being used as input to the second, and so on.
- The output of a DDL transform is *not* an XML document. Therefore, no transform should be added after the DDL transform.
- Each transform expects a certain format XML document as input. If the input document is unspecified, metadata XML format is assumed.
- When the `ALTERXML` transform is used, parse items are returned in a `PARSE_LIST` element of the `ALTER_XML` document. Each `PARSE_LIST_ITEM` element contains an `ITEM` and a `VALUE`. For example:

```
<PARSE_LIST>
  <PARSE_LIST_ITEM>
    <ITEM>XPATH</ITEM>
    <VALUE>/sxml:TABLE/sxml:RELATIONAL_TABLE/sxml:COL_LIST/sxml:COL_LIST_ITEM[14]</
VALUE>
  </PARSE_LIST_ITEM>
  <PARSE_LIST_ITEM>
    <ITEM>NAME</ITEM>
    <VALUE>Z1</VALUE>
  </PARSE_LIST_ITEM>
  <PARSE_LIST_ITEM>
    <ITEM>CLAUSE_TYPE</ITEM>
    <VALUE>ADD_COLUMN</VALUE>
  </PARSE_LIST_ITEM>
  <PARSE_LIST_ITEM>
    <ITEM>COLUMN_ATTRIBUTE</ITEM>
    <VALUE>NOT_NULL</VALUE>
  </PARSE_LIST_ITEM>
</PARSE_LIST>
```

### Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OPERATION`. `ADD_TRANSFORM` was called after the first call to `FETCH_XXX` for the `OPEN` context. After the first call to `FETCH_XXX` is made, no further calls to `ADD_TRANSFORM` for the current `OPEN` context are permitted.
- `INCONSISTENT_ARGS`. The arguments are inconsistent. Possible inconsistencies include the following:
  - `encoding` is specified even though `name` is not a URL.
  - `object_type` is not part of the collection designated by `handle`.

## 110.6.2 CLOSE Procedure

This procedure is used for both retrieval and submission. This procedure invalidates the handle returned by `OPEN` (or `OPENW`) and cleans up the associated state.

### See Also:

For more information about related subprograms:

- [Subprograms for Retrieving Multiple Objects From the Database](#)
- [Subprograms for Submitting XML to the Database](#)

### Syntax

```
DBMS_METADATA.CLOSE (  
    handle IN NUMBER);
```

### Parameters

**Table 110-6** CLOSE Procedure Parameters

| Parameter | Description                                                          |
|-----------|----------------------------------------------------------------------|
| handle    | The handle returned from <code>OPEN</code> (or <code>OPENW</code> ). |

### Usage Notes

#### Note:

The following notes apply only to object retrieval

You can prematurely terminate the stream of objects established by `OPEN` or `(OPENW)`.

- If a call to `FETCH_XXX` returns `NULL`, indicating no more objects, a call to `CLOSE` is made transparently. In this case, you can still call `CLOSE` on the handle and not get an exception. (The call to `CLOSE` is not required.)
- If you know that only one specific object will be returned, you should explicitly call `CLOSE` after the single `FETCH_XXX` call to free resources held by the handle.

### Exceptions

- `INVALID_ARGVAL`. The value for the `handle` parameter is `NULL` or invalid.

## 110.6.3 CONVERT Functions and Procedures

The `DBMS_METADATA.CONVERT` functions and procedures transform input XML documents.

The `CONVERT` functions return creation DDL. The `CONVERT` procedures return either XML or DDL, depending on the specified transforms.

**See Also:**

- [Subprograms for Submitting XML to the Database](#)

**Syntax**

The CONVERT functions are as follows:

```
DBMS_METADATA.CONVERT (  
    handle    IN NUMBER,  
    document  IN sys.XMLType)  
RETURN sys.ku$_multi_ddls;
```

```
DBMS_METADATA.CONVERT (  
    handle    IN NUMBER,  
    document  IN CLOB)  
RETURN sys.ku$_multi_ddls;
```

The CONVERT procedures are as follows:

```
DBMS_METADATA.CONVERT (  
    handle    IN NUMBER,  
    document  IN sys.XMLType,  
    result    IN OUT NOCOPY CLOB);
```

```
DBMS_METADATA.CONVERT (  
    handle    IN NUMBER,  
    document  IN CLOB,  
    result    IN OUT NOCOPY CLOB);
```

**Parameters**

**Table 110-7** CONVERT Subprogram Parameters

| Parameter | Description                                                                 |
|-----------|-----------------------------------------------------------------------------|
| handle    | The handle returned from OPENW                                              |
| document  | The XML document containing object metadata of the type of the OPENW handle |
| result    | The converted document                                                      |

**Return Values**

Either XML or DDL, depending on the specified transforms.

**Usage Notes**

You can think of CONVERT as the second half of FETCH\_xxx, either FETCH\_DDL (for the function variants) or FETCH\_CLOB (for the procedure variants). There are two differences:

- FETCH\_xxx gets its XML document from the database, but CONVERT gets its XML document from the caller
- FETCH\_DDL returns its results in a sys.ku\$\_ddls nested table, but CONVERT returns a sys.ku\$\_multi\_ddls nested table

The transforms specified with `ADD_TRANSFORM` are applied in turn, and the result is returned to the caller. For the function variants, the DDL transform must be specified. If parse items were specified, they are returned in the `parsedItems` column. Parse items are ignored by the procedure variants.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in `OPENW`.

### Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INCONSISTENT_OPERATION`. No transform was specified. The DDL transform was not specified (function variants only).
- `INCOMPATIBLE_DOCUMENT`. The version of the XML document is not compatible with this version of the software.

## 110.6.4 FETCH\_xxx Functions and Procedures

These functions and procedures return metadata for objects meeting the criteria established by `OPEN`, `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, and so on.

See "[Usage Notes](#)" for the variants.

### See Also:

For more information about related subprograms:

- [Subprograms for Retrieving Multiple Objects From the Database](#)

### Syntax

The `FETCH` functions are as follows:

```
DBMS_METADATA.FETCH_XML (
    handle IN NUMBER)
RETURN sys.XMLType;

DBMS_METADATA.FETCH_DDL (
    handle IN NUMBER)
RETURN sys.ku$_ddl;

DBMS_METADATA.FETCH_CLOB (
    handle          IN NUMBER,
    cache_lob       IN BOOLEAN DEFAULT TRUE,
    lob_duration    IN PLS_INTEGER DEFAULT DBMS_LOB.SESSION)
RETURN CLOB;
```

The `FETCH` procedures are as follows:

```
DBMS_METADATA.FETCH_CLOB (
    handle IN NUMBER,
    doc    IN OUT NOCOPY CLOB);

DBMS_METADATA.FETCH_XML_CLOB (
```

```

handle IN NUMBER,
doc IN OUT NOCOPY CLOB,
parsed_items OUT sys.ku$_parsed_items,
object_type_path OUT VARCHAR2);

```

## Parameters

**Table 110-8 FETCH\_XXX Function Parameters**

| Parameters       | Description                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle           | The handle returned from OPEN.                                                                                                                                                                       |
| cache_lob        | TRUE=read LOB into buffer cache                                                                                                                                                                      |
| lob_duration     | The duration for the temporary LOB created by FETCH_CLOB, either DBMS_LOB.SESSION (the default) or DBMS_LOB.CALL.                                                                                    |
| doc              | The metadata for the objects, or NULL if all objects have been returned.                                                                                                                             |
| parsed_items     | A nested table containing the items specified by SET_PARSE_ITEM. If SET_PARSE_ITEM was not called, a NULL is returned.                                                                               |
| object_type_path | For heterogeneous object types, this is the full path name of the object type for the objects returned by the call to FETCH_XXX. If handle designates a homogeneous object type, a NULL is returned. |

## Return Values

The metadata for the objects or NULL if all objects have been returned.

## Usage Notes

These functions and procedures return metadata for objects meeting the criteria established by the call to OPEN that returned the handle, and subsequent calls to SET\_FILTER, SET\_COUNT, ADD\_TRANSFORM, and so on. Each call to FETCH\_XXX returns the number of objects specified by SET\_COUNT (or less, if fewer objects remain in the underlying cursor) until all objects have been returned. After the last object is returned, subsequent calls to FETCH\_XXX return NULL and cause the stream created by OPEN to be transparently closed.

There are several different FETCH\_XXX functions and procedures:

- The `FETCH_XML` function returns the XML metadata for an object as an `XMLType`. It assumes that if any transform has been specified, that transform will produce an XML document. In particular, it assumes that the DDL transform has not been specified.
- The `FETCH_DDL` function returns the DDL (to create the object) in a `sys.ku$_ddls` nested table. It assumes that the DDL transform has been specified. Each row of the `sys.ku$_ddls` nested table contains a single DDL statement in the `ddlText` column; if requested, parsed items for the DDL statement will be returned in the `parsedItems` column. Multiple DDL statements may be returned under the following circumstances:
  - When you call `SET_COUNT` to specify a count greater than 1
  - When an object is transformed into multiple DDL statements. For example, A `TYPE` object that has a DDL transform applied to it can be transformed into both `CREATE TYPE` and `CREATE TYPE BODY` statements. A `TABLE` object can be transformed into a `CREATE TABLE`, and one or more `ALTER TABLE` statements
- The `FETCH_CLOB` function simply returns the object, transformed or not, as a CLOB. By default, the CLOB is read into the buffer cache and has session duration, but these defaults can be overridden with the `cache_lob` and `lob_duration` parameters.

- The `FETCH_CLOB` procedure returns the objects by reference in an `IN OUT NOCOPY` parameter. This is faster than the function variant, which returns LOBs by value, a practice that involves an expensive LOB copy.
- The `FETCH_XML_CLOB` procedure returns the XML metadata for the objects as a CLOB in an `IN OUT NOCOPY` parameter. This helps to avoid LOB copies, which can consume a lot of resources. It also returns a nested table of parse items and the full path name of the object type of the returned objects.
- All LOBs returned by `FETCH_xxx` are temporary LOBs. You must free the LOB. If the LOB is supplied as an `IN OUT NOCOPY` parameter, you must also create the LOB.
- If `SET_PARSE_ITEM` was called, `FETCH_DDL` and `FETCH_XML_CLOB` return attributes of the object's metadata (or the DDL statement) in a `sys.ku$_parsed_items` nested table. For `FETCH_XML_CLOB`, the nested table is an `OUT` parameter. For `FETCH_DDL`, it is a column in the returned `sys.ku$_ddls` nested table. Each row of the nested table corresponds to an item specified by `SET_PARSE_ITEM` and contains the following columns:
  - `item`—the name of the attribute as specified in the `name` parameter to `SET_PARSE_ITEM`.
  - `value`—the attribute value, or `NULL` if the attribute is not present in the DDL statement.
  - `object_row`—a positive integer indicating the object to which the parse item applies. If multiple objects are returned by `FETCH_xxx`, (because `SET_COUNT` specified a count greater than 1) then `object_row=1` for all items for the first object, 2 for the second, and so on.
- The rows of the `sys.ku$_parsed_items` nested table are ordered by ascending `object_row`, but otherwise the row order is undetermined. To find a particular parse item within an object row the caller must search the table for a match on `item`.
- In general there is no guarantee that a requested parse item will be returned. For example, the parse item may not apply to the object type or to the particular line of DDL, or the item's value may be `NULL`.
- If `SET_PARSE_ITEM` was not called, `NULL` is returned as the value of the parsed items nested table.
- It is expected that the same variant of `FETCH_xxx` will be called for all objects selected by `OPEN`. That is, programs will not intermix calls to `FETCH_XML`, `FETCH_DDL`, `FETCH_CLOB`, and so on using the same `OPEN` handle. The effect of calling different variants is undefined; it might do what you expect, but there are no guarantees.
- Every object fetched will be internally consistent with respect to on-going DDL (and the subsequent recursive DML) operations against the dictionary. In some cases, multiple queries may be issued, either because the object type is heterogeneous or for performance reasons (for example, one query for heap tables, one for index-organized tables). Consequently the `FETCH_xxx` calls may in fact be fetches from different underlying cursors (meaning that read consistency is not guaranteed).

 **Caution:**

Do not run functions and procedures within a query, because they can fail when the handle is for an open context for a heterogeneous object.

## Exceptions

Most exceptions raised during execution of the query are propagated to the caller. Also, the following exceptions may be raised:

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INCONSISTENT_OPERATION`. Either `FETCH_XML` was called when the DDL transform had been specified, or `FETCH_DDL` was called when the DDL transform had *not* been specified.

## 110.6.5 GET\_xxx Functions

`GET_xxx` functions let you fetch metadata for objects with a single call.

These `GET_xxx` functions are:

- `GET_XML`
- `GET_DDL`
- `GET_SXML`
- `GET_DEPENDENT_XML`
- `GET_DEPENDENT_DDL`
- `GET_GRANTED_XML`
- `GET_GRANTED_DDL`

## Syntax

```
DBMS_METADATA.GET_XML (
object_type      IN VARCHAR2,
name             IN VARCHAR2,
schema          IN VARCHAR2 DEFAULT NULL,
version          IN VARCHAR2 DEFAULT 'COMPATIBLE',
model            IN VARCHAR2 DEFAULT 'ORACLE',
transform        IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

```
DBMS_METADATA.GET_DDL (
object_type      IN VARCHAR2,
name             IN VARCHAR2,
schema          IN VARCHAR2 DEFAULT NULL,
version          IN VARCHAR2 DEFAULT 'COMPATIBLE',
model            IN VARCHAR2 DEFAULT 'ORACLE',
transform        IN VARCHAR2 DEFAULT 'DDL')
RETURN CLOB;
```

```
DBMS_METADATA.GET_SXML (
object_type      IN VARCHAR2,
```

```

name          IN VARCHAR2 DEFAULT NULL,
schema        IN VARCHAR2 DEFAULT NULL,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE',
transform     IN VARCHAR2 DEFAULT 'SXML')
RETURN CLOB;

DBMS_METADATA.GET_DEPENDENT_XML (
object_type   IN VARCHAR2,
base_object_name IN VARCHAR2,
base_object_schema IN VARCHAR2 DEFAULT NULL,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE',
transform     IN VARCHAR2 DEFAULT NULL,
object_count  IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_DEPENDENT_DDL (
object_type   IN VARCHAR2,
base_object_name IN VARCHAR2,
base_object_schema IN VARCHAR2 DEFAULT NULL,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE',
transform     IN VARCHAR2 DEFAULT 'DDL',
object_count  IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_GRANTED_XML (
object_type   IN VARCHAR2,
grantee       IN VARCHAR2 DEFAULT NULL,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE',
transform     IN VARCHAR2 DEFAULT NULL,
object_count  IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_GRANTED_DDL (
object_type   IN VARCHAR2,
grantee       IN VARCHAR2 DEFAULT NULL,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE',
transform     IN VARCHAR2 DEFAULT 'DDL',
object_count  IN NUMBER   DEFAULT 10000)
RETURN CLOB;

```

## Parameters

**Table 110-9 GET\_xxx Function Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_type | The type of object to be retrieved. This parameter takes the same values as the OPEN object_type parameter, except that it cannot be a heterogeneous object type. The attributes of the object type must be appropriate to the function. That is, for GET_xxx it must be a named object. |
| name        | The object name. It is used internally in a NAME filter. (If the name is longer than 30 characters, it will be used in a LONGNAME filter.) If this parameter is NULL, then no NAME or LONGNAME filter is specified. See <a href="#">Table 110-18</a> for a list of filters.              |

**Table 110-9 (Cont.) GET\_xxx Function Parameters**

| Parameter          | Description                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema             | The object schema. It is used internally in a <code>SCHEMA</code> filter. The default is the current user.                                                                                      |
| version            | The version of metadata to be extracted. This parameter takes the same values as the <code>OPEN</code> version parameter.                                                                       |
| model              | The object model to use. This parameter takes the same values as the <code>OPEN</code> model parameter.                                                                                         |
| transform          | The name of a transformation on the output. This parameter takes the same values as the <code>ADD_TRANSFORM</code> name parameter. For <code>GET_XML</code> this must not be <code>DDL</code> . |
| base_object_name   | The base object name. It is used internally in a <code>BASE_OBJECT_NAME</code> filter.                                                                                                          |
| base_object_schema | The base object schema. It is used internally in a <code>BASE_OBJECT_SCHEMA</code> filter. The default is the current user.                                                                     |
| grantee            | The grantee. It is used internally in a <code>GRANTEE</code> filter. The default is the current user.                                                                                           |
| object_count       | The maximum number of objects to return. See <a href="#">SET_COUNT Procedure</a> .                                                                                                              |

**Return Values**

The metadata for the specified object as XML or DDL.

**Usage Notes**

- These functions allow you to fetch metadata for objects with a single call. They encapsulate calls to `OPEN`, `SET_FILTER`, and so on. The function you use depends on the characteristics of the object type and on whether you want XML, SXML, or DDL.
  - `GET_xxx` is used to fetch named objects, especially schema objects (tables, views).
  - `GET_DEPENDENT_xxx` is used to fetch dependent objects (audits, object grants).
  - `GET_GRANTED_xxx` is used to fetch granted objects (system grants, role grants).
- For some object types you can use more than one function. For example, you can use `GET_xxx` to fetch an index by name, or `GET_DEPENDENT_xxx` to fetch the same index by specifying the table on which it is defined.
- `GET_xxx` only returns a single named object.
- For `GET_DEPENDENT_xxx` and `GET_GRANTED_xxx`, an arbitrary number of dependent or granted objects can match the input criteria. You can specify an object count when fetching these objects. (The default count of 10000 should be adequate in most cases.)
- If the DDL transform is specified, session-level transform parameters are inherited.
- If you invoke these functions from SQL\*Plus, you should set the `PAGESIZE` to 0 and set `LONG` to some large number to get complete, uninterrupted output.

**Exceptions**

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- `OBJECT_NOT_FOUND`. The specified object was not found in the database.

### Examples

Example: Fetch the XML Representation of SCOTT.EMP

To generate complete, uninterrupted output, set the `PAGESIZE` to 0 and set `LONG` to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
SELECT DBMS_METADATA.GET_XML('TABLE','EMP','SCOTT')
FROM DUAL;
```

Example: Fetch the DDL for all Complete Tables in the Current Schema, Filter Out Nested Tables and Overflow Segments

This example fetches the DDL for all "complete" tables in the current schema, filtering out nested tables and overflow segments. The example uses `SET_TRANSFORM_PARAM` (with the handle value = `DBMS_METADATA.SESSION_TRANSFORM` meaning "for the current session") to specify that storage clauses are not to be returned in the SQL DDL. Afterwards, the example resets the session-level parameters to their defaults.

To generate complete, uninterrupted output, set the `PAGESIZE` to 0 and set `LONG` to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
EXECUTE
DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'STORAGE',false);
SELECT DBMS_METADATA.GET_DDL('TABLE',u.table_name)
FROM USER_ALL_TABLES u
WHERE u.nested='NO'
AND (u.iot_type is null or u.iot_type='IOT');
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'DEFAULT');
```

Example: Fetch the DDL For All Object Grants On HR.EMPLOYEES

```
SELECT DBMS_METADATA.GET_DEPENDENT_DDL('OBJECT_GRANT',
'EMPLOYEES','HR') FROM DUAL;
```

Example: Fetch the DDL For All System Grants Granted To SCOTT

```
SELECT DBMS_METADATA.GET_GRANTED_DDL('SYSTEM_GRANT','SCOTT')
FROM DUAL;
```

## 110.6.6 GET\_QUERY Function

This function returns the text of the queries that are used by `FETCH_XXX`. This function assists in debugging.

### See Also:

For more information about related subprograms:

- [Subprograms for Retrieving Multiple Objects From the Database](#)

## Syntax

```
DBMS_METADATA.GET_QUERY (  
    handle IN NUMBER)  
RETURN VARCHAR2;
```

## Parameters

**Table 110-10 GET\_QUERY Function Parameters**

| Parameter | Description                                                                             |
|-----------|-----------------------------------------------------------------------------------------|
| handle    | The handle returned from OPEN. It cannot be the handle for a heterogeneous object type. |

## Return Values

The text of the queries that will be used by `FETCH_XXX`.

## Exceptions

- INVALID\_ARGVAL. A NULL or invalid value was supplied for the `handle` parameter.

## 110.6.7 OPEN Function

The `DBMS_METADATA.OPEN` function specifies the type of object to be retrieved, the version of its metadata, and the object model.

The return value is an opaque context handle for the set of objects to be used in subsequent calls.

## Syntax

```
DBMS_METADATA.OPEN (  
    object_type IN VARCHAR2,  
    version      IN VARCHAR2 DEFAULT 'COMPATIBLE',  
    model        IN VARCHAR2 DEFAULT 'ORACLE',  
    network_link IN VARCHAR2 DEFAULT NULL)  
RETURN NUMBER;
```

## Parameters

**Table 110-11 Open Function Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_type  | <p>The type of object to be retrieved. The table <code>DBMS_METADATA: Object Types</code> lists the valid type names and their meanings. These object types are supported for the <code>ORACLE</code> model of metadata (see <code>model</code> in this table).</p> <p>The Attributes column in the <code>DBMS_METADATA: Object Types</code> table specifies some object type attributes:</p> <ul style="list-style-type: none"> <li>• Schema objects, such as tables, belong to schemas.</li> <li>• Named objects have unique names (if they are schema objects, the name is unique to the schema).</li> <li>• Dependent objects, such as indexes, are defined with reference to a base schema object.</li> <li>• Granted objects are granted or assigned to a user or role and therefore have a named grantee.</li> <li>• Heterogeneous object types denote a collection of related objects of different types. See the table "Object Types Returned for the Heterogeneous Object Type" for a listing of object types returned for the heterogeneous object type.</li> </ul> <p>These attributes are relevant when choosing object selection criteria. See "<a href="#">SET_FILTER Procedure</a>" for more information.</p> |
| version      | <p>The version of metadata to be extracted. Database objects or attributes that are incompatible with the version will not be extracted. Legal values for this parameter are as follows:</p> <p><code>COMPATIBLE</code> (default)—the version of the metadata corresponds to the database compatibility level.</p> <p><code>LATEST</code>—the version of the metadata corresponds to the database version.</p> <p>A specific database version. The value cannot be lower than 9.2.0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| model        | <p>Specifies which view to use, because the API can support multiple views on the metadata. Only the <code>ORACLE</code> model is supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| network_link | <p>The name of a database link to the database whose metadata is to be retrieved. If <code>NULL</code> (the default), then metadata is retrieved from the database on which the caller is running</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The table "`DBMS_METADATA: Object Types`" provides the name, meaning, attributes, and notes for the `DBMS_METADATA` package object types. In the attributes column, `S` represents a schema object, `N` represents a named object, `D` represents a dependent object, `G` represents a granted object, and `H` represents a heterogeneous object.

**Table 110-12 DBMS\_METADATA: Object Types**

| Type Name                   | Meaning                              | Attributes       | Notes              |
|-----------------------------|--------------------------------------|------------------|--------------------|
| <code>AQ_QUEUE</code>       | queues                               | <code>SND</code> | Dependent on table |
| <code>AQ_QUEUE_TABLE</code> | additional metadata for queue tables | <code>ND</code>  | Dependent on table |
| <code>AQ_TRANSFORM</code>   | transforms                           | <code>SN</code>  | None               |
| <code>ASSOCIATION</code>    | associate statistics                 | <code>D</code>   | None               |

**Table 110-12 (Cont.) DBMS\_METADATA: Object Types**

| Type Name             | Meaning                            | Attributes | Notes                                                                                                                                                                                                                     |
|-----------------------|------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUDIT                 | audits of SQL statements           | DG         | Modeled as dependent, granted object. The base object name is the statement audit option name (for example, ALTER SYSTEM). There is no base object schema. The grantee is the user or proxy whose statements are audited. |
| AUDIT_OBJ             | audits of schema objects           | D          | None                                                                                                                                                                                                                      |
| CLUSTER               | clusters                           | SN         | None                                                                                                                                                                                                                      |
| COMMENT               | comments                           | D          | None                                                                                                                                                                                                                      |
| CONSTRAINT            | constraints                        | SND        | Does not include: <ul style="list-style-type: none"> <li>primary key constraint for IOT</li> <li>column NOT NULL constraints</li> <li>certain REF SCOPE and WITH ROWID constraints for tables with REF columns</li> </ul> |
| CONTEXT               | application contexts               | N          | None                                                                                                                                                                                                                      |
| DATABASE_EXPORT       | all metadata objects in a database | H          | Corresponds to a full database export                                                                                                                                                                                     |
| DB_LINK               | database links                     | SN         | Modeled as schema objects because they have owners. For public links, the owner is PUBLIC. For private links, the creator is the owner.                                                                                   |
| DEFAULT_ROLE          | default roles                      | G          | Granted to a user by ALTER USER                                                                                                                                                                                           |
| DIMENSION             | dimensions                         | SN         | None                                                                                                                                                                                                                      |
| DIRECTORY             | directories                        | N          | None                                                                                                                                                                                                                      |
| FGA_POLICY            | fine-grained audit policies        | D          | Not modeled as named object because policy names are not unique.                                                                                                                                                          |
| FUNCTION              | stored functions                   | SN         | None                                                                                                                                                                                                                      |

**Table 110-12 (Cont.) DBMS\_METADATA: Object Types**

| Type Name    | Meaning                                   | Attributes | Notes                          |
|--------------|-------------------------------------------|------------|--------------------------------|
| XS_NAMESPACE | Real Application Security (RAS) namespace | N          | Corresponds to RAS namespaces. |

The following table lists the types of objects returned for the major heterogeneous object types. For SCHEMA\_EXPORT, certain object types are only returned if the INCLUDE\_USER filter is specified at TRUE. In the table, such object types are marked INCLUDE\_USER.

**Table 110-13 Object Types Returned for the Heterogeneous Object Type**

## Return Values

An opaque handle to the class of objects. This handle is used as input to `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, `GET_QUERY`, `SET_PARSE_ITEM`, `FETCH_xxx`, and `CLOSE`.

## Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OBJECT_PARAM`. The `version` or `model` parameter was not valid for the `object_type`.

## 110.6.8 OPENW Function

This function specifies the type of object to be submitted and the object model. The return value is an opaque context handle.

## Syntax

```
DBMS_METADATA.OPENW
(object_type IN VARCHAR2,
 version     IN VARCHAR2 DEFAULT 'COMPATIBLE',
 model       IN VARCHAR2 DEFAULT 'ORACLE')
RETURN NUMBER;
```

## Parameters

**Table 110-14 OPENW Function Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object_type</code> | The type of object to be submitted. Valid types names and their meanings are listed in <a href="#">Table 110-12</a> . The type cannot be a heterogeneous object type.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>version</code>     | The version of DDL to be generated by the <code>CONVERT</code> function. DDL clauses that are incompatible with the version will not be generated. The legal values for this parameter are as follows: <ul style="list-style-type: none"> <li>• <code>COMPATIBLE</code> - This is the default. The version of the DDL corresponds to the database compatibility level. Database compatibility must be set to 9.2.0 or higher.</li> <li>• <code>LATEST</code> - The version of the DDL corresponds to the database version.</li> <li>• A specific database version. The value cannot be lower than 9.2.0.</li> </ul> |
| <code>model</code>       | Specifies which view to use. Only the Oracle proprietary ( <code>ORACLE</code> ) view is supported by <code>DBMS_METADATA</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Return Values

An opaque handle to write context. This handle is used as input to the `ADD_TRANSFORM`, `CONVERT`, `PUT`, and `CLOSE` procedures.

### Exceptions

- `INVALID_ARGVAL`. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OBJECT_PARAM`. The `model` parameter was not valid for the `object_type`.

## 110.6.9 PUT Function

This function submits an XML document containing object metadata to the database to create the object.

### See Also:

For more information about related subprograms:

- [Subprograms for Submitting XML to the Database](#)

### Syntax

```
DBMS_METADATA.PUT (  
    handle      IN          NUMBER,  
    document    IN          sys.XMLType,  
    flags       IN          NUMBER,  
    results     IN OUT NOCOPY sys.ku$_SubmitResults)  
RETURN BOOLEAN;
```

```
DBMS_METADATA.PUT (  
    handle      IN          NUMBER,  
    document    IN          CLOB,  
    flags       IN          NUMBER,  
    results     IN OUT NOCOPY sys.ku$_SubmitResults)  
RETURN BOOLEAN;
```

### Parameters

**Table 110-15** PUT Function Parameters

| Parameter | Description                                                                                |
|-----------|--------------------------------------------------------------------------------------------|
| handle    | The handle returned from <code>OPENW</code> .                                              |
| document  | The XML document containing object metadata for the type of the <code>OPENW</code> handle. |
| flags     | Reserved for future use                                                                    |
| results   | Detailed results of the operation.                                                         |

### Return Values

`TRUE` if all SQL operations succeeded; `FALSE` if there were any errors.

## Usage Notes

The `PUT` function converts the XML document to DDL just as `CONVERT` does (applying the specified transforms in turn) and then submits each resultant DDL statement to the database. As with `CONVERT`, the DDL transform must be specified. The DDL statements and associated parse items are returned in the `sys.ku$_SubmitResults` nested table. With each DDL statement is a nested table of error lines containing any errors or exceptions raised by the statement.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in `OPENW`.

## Exceptions

- `INVALID_ARGVAL`. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INCONSISTENT_OPERATION`. The DDL transform was not specified.
- `INCOMPATIBLE_DOCUMENT`. The version of the XML document is not compatible with this version of the software.

## 110.6.10 SET\_COUNT Procedure

This procedure specifies the maximum number of objects to be retrieved in a single `FETCH_XXX` call.

By default, each call to `FETCH_XXX` returns one object. You can use the `SET_COUNT` procedure to override this default. If `FETCH_XXX` is called from a client, specifying a count value greater than 1 can result in fewer server round trips and, therefore, improved performance.

For heterogeneous object types, a single `FETCH_XXX` operation only returns objects of a single object type.

- [Subprograms for Retrieving Multiple Objects From the Database](#)

## Syntax

```
DBMS_METADATA.SET_COUNT (
    handle          IN NUMBER,
    value           IN NUMBER,
    object_type_path IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 110-16 SET\_COUNT Procedure Parameters**

| Parameter | Description                                  |
|-----------|----------------------------------------------|
| handle    | The handle returned from <code>OPEN</code> . |

**Table 110-16 (Cont.) SET\_COUNT Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value            | The maximum number of objects to retrieve.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| object_type_path | <p>A path name designating the object types to which the count value applies. By default, the count value applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, behavior can be either of the following:</p> <ul style="list-style-type: none"> <li>If object_type_path is omitted, then the count applies to all object types within the heterogeneous collection.</li> <li>If object_type_path is specified, then the count only applies to the specific node (or set of nodes) within the tree of object types forming the heterogeneous collection.</li> </ul> |

### Exceptions

- INVALID\_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INVALID\_OPERATION. SET\_COUNT was called after the first call to FETCH\_xxx for the OPEN context. After the first call to FETCH\_xxx is made, no further calls to SET\_COUNT for the current OPEN context are permitted.
- INCONSISTENT\_ARGS. object\_type parameter is not consistent with handle.

## 110.6.11 SET\_FILTER Procedure

This procedure specifies restrictions on the objects to be retrieved, for example, the object name or schema.

### See Also:

For more information about related subprograms:

- [Subprograms for Retrieving Multiple Objects From the Database](#)

### Syntax

```
DBMS_METADATA.SET_FILTER (
    handle          IN NUMBER,
    name            IN VARCHAR2,
    value           IN VARCHAR2,
    object_type_path IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_FILTER (
    handle          IN NUMBER,
    name            IN VARCHAR2,
    value           IN BOOLEAN DEFAULT TRUE,
    object_type_path IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_FILTER (
    handle          IN NUMBER,
    name            IN VARCHAR2,
```

```
value          IN NUMBER,
object_type_path IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 110-17 SET\_FILTER Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle           | The handle returned from OPEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| name             | <p>The name of the filter. For each filter, <a href="#">Table 110-18</a> lists the object_type it applies to, its name, its datatype (text or Boolean), and its meaning or effect (including its default value, if any).</p> <p>The Datatype column of <a href="#">Table 110-18</a> also indicates whether a text filter is an expression filter. An expression filter is the right-hand side of a SQL comparison (that is, a SQL comparison operator (=, !=, and so on.)) and the value compared against. The value must contain parentheses and quotation marks where appropriate. Note that in PL/SQL and SQL*Plus, two single quotes (<i>not</i> a double quote) are needed to represent an apostrophe. For example, an example of a NAME_EXPR filter in PL/SQL is as follows:</p> <pre>'IN ('DEPT','EMP')'</pre> <p>The filter value is combined with a particular object attribute to produce a WHERE condition in the query that fetches the objects. In the preceding example, the filter is combined with the attribute corresponding to an object name; objects named 'DEPT' and 'EMP' are selected.</p> |
| value            | The value of the filter. Text, Boolean, and Numeric filters are supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| object_type_path | <p>A path name designating the object types to which the filter applies. By default, the filter applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, you can use this parameter to specify a filter for a specific node or set of nodes within the tree of object types that form the heterogeneous collection. See <a href="#">Table 110-19</a> for a listing of some of the values for this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

[Table 110-18](#) describes the object type, name, datatype, and meaning of the filters available with the SET\_FILTER procedure.

**Table 110-18 SET\_FILTER: Filters**

| Object Type   | Name              | Datatype        | Meaning                                                                                                                                                                                                                                   |
|---------------|-------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Named objects | NAME              | Text            | Objects with this exact name are selected.                                                                                                                                                                                                |
| Named objects | NAME_EXPR         | Text expression | <p>The filter value is combined with the object attribute corresponding to the object name to produce a WHERE condition in the query that fetches the objects.</p> <p>By default, all named objects of object_type are selected.</p>      |
| Named objects | EXCLUDE_NAME_EXPR | Text expression | <p>The filter value is combined with the attribute corresponding to the object name to specify objects that are to be excluded from the set of objects fetched.</p> <p>By default, all named objects of the object type are selected.</p> |

**Table 110-18 (Cont.) SET\_FILTER: Filters**

| Object Type                                                           | Name               | Datatype        | Meaning                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------|--------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE_EXPORT                                                          | EXCLUDE_TABLES     | Boolean         | If TRUE, all paths associated with tables are excluded from the set of objects fetched. If FALSE (the default), all paths associated with tables are fetched.                                                                                                                                                              |
| Schema objects                                                        | SCHEMA             | Text            | Objects in this schema are selected. If the object type is SYNONYM, then specify PUBLIC to select public synonyms.                                                                                                                                                                                                         |
| Schema objects                                                        | SCHEMA_EXPR        | Text expression | The filter value is combined with the attribute corresponding to the object's schema.<br>The default is determined as follows:<br>- if BASE_OBJECT_SCHEMA is specified, then objects in that schema are selected;<br>- otherwise, objects in the current schema are selected.                                              |
| PACKAGE, TYPE                                                         | SPECIFICATION      | Boolean         | If TRUE, retrieve the package or type specification. Defaults to TRUE.                                                                                                                                                                                                                                                     |
| PACKAGE, TYPE                                                         | BODY               | Boolean         | If TRUE, retrieve the package or type body. Defaults to TRUE.                                                                                                                                                                                                                                                              |
| TABLE, CLUSTER, INDEX, TABLE_DATA, TABLE_EXPORT, TRANSPORTABLE_EXPORT | TABLESPACE         | Text            | Objects in this tablespace (or having a partition in this tablespace) are selected.                                                                                                                                                                                                                                        |
| TABLE, CLUSTER, INDEX, TABLE_DATA, TABLE_EXPORT, TRANSPORTABLE_EXPORT | TABLESPACE_EXPR    | Text expression | The filter value is combined with the attribute corresponding to the object's tablespace (or in the case of a partitioned table or index, the partition's tablespaces). By default, objects in all tablespaces are selected.                                                                                               |
| TABLE, objects dependent on tables                                    | PRIMARY            | Boolean         | If TRUE, retrieve primary tables (that is, tables for which the secondary object bit in obj\$ is clear. Defaults to TRUE.                                                                                                                                                                                                  |
| TABLE, objects dependent on tables                                    | SECONDARY          | Boolean         | If TRUE, retrieve secondary tables (that is, tables for which the secondary object bit in obj\$ is set). Defaults to TRUE.                                                                                                                                                                                                 |
| Dependent Objects                                                     | BASE_OBJECT_NAME   | Text            | Objects are selected that are defined or granted on objects with this name. Specify SCHEMA for triggers on schemas. Specify DATABASE for database triggers. Column-level comments cannot be selected by column name; the base object name must be the name of the table, view, or materialized view containing the column. |
| Dependent Objects                                                     | BASE_OBJECT_SCHEMA | Text            | Objects are selected that are defined or granted on objects in this schema. If BASE_OBJECT_NAME is specified with a value other than SCHEMA or DATABASE, this defaults to the current schema.                                                                                                                              |

**Table 110-18 (Cont.) SET\_FILTER: Filters**

| Object Type                           | Name                          | Datatype        | Meaning                                                                                                                                                                                                                 |
|---------------------------------------|-------------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dependent Objects                     | BASE_OBJECT_NAME_EXPR         | Text expression | The filter value is combined with the attribute corresponding to the name of the base object.<br>Not valid for schema and database triggers.                                                                            |
| Dependent Objects                     | EXCLUDE_BASE_OBJECT_NAME_EXPR | Text expression | The filter value is combined with the attribute corresponding to the name of the base object to specify objects that are to be excluded from the set of objects fetched.<br>Not valid for schema and database triggers. |
| Dependent Objects                     | BASE_OBJECT_SCHEMA_EXPR       | Text expression | The filter value is combined with the attribute corresponding to the schema of the base object.                                                                                                                         |
| Dependent Objects                     | BASE_OBJECT_TYPE              | Text            | The object type of the base object.                                                                                                                                                                                     |
| Dependent Objects                     | BASE_OBJECT_TYPE_EXPR         | Text expression | The filter value is combined with the attribute corresponding to the object type of the base object.<br>By default no filtering is done on object type.                                                                 |
| Dependent Objects                     | BASE_OBJECT_TABLESPACE        | Text            | The tablespace of the base object.                                                                                                                                                                                      |
| Dependent Objects                     | BASE_OBJECT_TABLESPACE_EXPR   | Text expression | The filter value is combined with the attribute corresponding to the tablespaces of the base object. By default, no filtering is done on the tablespace.                                                                |
| INDEX, TRIGGER                        | SYSTEM_GENERATED              | Boolean         | If TRUE, select indexes or triggers even if they are system-generated. If FALSE, omit system-generated indexes or triggers. Defaults to TRUE.                                                                           |
| Granted Objects                       | GRANTEE                       | Text            | Objects are selected that are granted to this user or role. Specify PUBLIC for grants to PUBLIC.                                                                                                                        |
| Granted Objects                       | PRIVNAME                      | Text            | The name of the privilege or role to be granted. For TABLESPACE_QUOTA, only UNLIMITED can be specified.                                                                                                                 |
| Granted Objects                       | GRANTEE_EXPR                  | Text expression | The filter value is combined with the attribute corresponding to the grantee name.                                                                                                                                      |
| Granted Objects                       | EXCLUDE_GRANTEE_EXPR          | Text expression | The filter value is combined with the attribute corresponding to the grantee name to specify objects that are to be excluded from the set of objects fetched.                                                           |
| OBJECT_GRANT                          | GRANTOR                       | Text            | Object grants are selected that are granted by this user.                                                                                                                                                               |
| SYNONYM,<br>JAVA_SOURCE,<br>XMLSCHEMA | LONGNAME                      | Text            | A name longer than 30 characters. Objects with this exact name are selected. If the object name is 30 characters or less, the NAME filter must be used.                                                                 |
| SYNONYM,<br>JAVA_SOURCE,<br>XMLSCHEMA | LONGNAME_EXPR                 | Text            | The filter value is combined with the attribute corresponding to the object's long name. By default, no filtering is done on the long name of an object.                                                                |

**Table 110-18 (Cont.) SET\_FILTER: Filters**

| Object Type   | Name          | Datatype        | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All objects   | CUSTOM_FILTER | Text            | <p>The text of a WHERE condition. The condition is appended to the query that fetches the objects. By default, no custom filter is used.</p> <p>The other filters are intended to meet the needs of the majority of users. Use CUSTOM_FILTER when no defined filters exists for your purpose. Of necessity such a filter depends on the detailed structure of the UDTs and views used in the query. Because filters may change from version to version, upward compatibility is not guaranteed.</p> |
| All objects   | EDITION       | Text            | <p>The edition filter is accepted for any object type, but affects only objects that support editions. The filter is only accepted for local objects (that is, the network_link parameter is not specified in the OPEN call). The edition name must be a valid edition name. If an edition is not specified, the edition of the active session is used.</p>                                                                                                                                         |

Objects normally fetched after this object type will not be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Heterogeneous objects | INCLUDE_PATH_EXPR,<br>EXCLUDE_PATH_EXPR | Text expression | For these two filters, the filter value is combined with the attribute corresponding to an object type path name to produce a WHERE condition in the query that fetches the object types belonging to the heterogeneous collection. Objects of types satisfying this condition are included (INCLUDE_PATH_EXPR) or excluded (EXCLUDE_PATH_EXPR) from the set of object types fetched. Path names in the filter value do not have to be fully qualified. See <a href="#">Table 110-19</a> for valid path names that can be used with these filters.<br><br>BEGIN_WITH, BEGIN_AFTER, END_BEFORE, END_WITH, INCLUDE_PATH_EXPR, and EXCLUDE_PATH_EXPR all restrict the set of object types in the heterogeneous collection. By default, objects of all object types in the heterogeneous collection are retrieved. |

#### Usage Notes

- Each call to SET\_FILTER causes a WHERE condition to be added to the underlying query that fetches the set of objects. The WHERE conditions are concatenated with the AND keyword so that you can use multiple SET\_FILTER calls to refine the set of objects to be returned. For example to specify that you want the object named EMP in schema SCOTT, do the following:

```
SET_FILTER(handle, 'SCHEMA', 'SCOTT');
SET_FILTER(handle, 'NAME', 'EMP');
```

- You can use the same text expression filter multiple times with different values. All the filter conditions will be applied to the query. For example, to get objects with names between Felix and Oscar, do the following:

```
SET_FILTER(handle, 'NAME_EXPR', '>=' 'FELIX');
SET_FILTER(handle, 'NAME_EXPR', '<=' 'OSCAR');
```

- With `SET_FILTER`, you can specify the schema of objects to be retrieved, but security considerations may override this specification. If the caller is `SYS` or has the `SELECT_CATALOG_ROLE` role, then any object can be retrieved; otherwise, only the following can be retrieved:
  - Schema objects owned by the current user
  - Public synonyms
  - System privileges granted to the current user or to `PUBLIC`
  - Grants on objects for which the current user is owner, grantor, or grantee (either explicitly or as `PUBLIC`).
  - `SCHEMA_EXPORT` where the `name` is the current user
  - `TABLE_EXPORT` where `SCHEMA` is the current user

If you request objects that you are not privileged to retrieve, no exception is raised; the object is not retrieved, as if it did not exist.

In stored procedures, functions, and definers-rights packages, roles (such as `SELECT_CATALOG_ROLE`) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker's possession of `SELECT_CATALOG_ROLE`), you must make the program invokers-rights.

- For heterogeneous object types, the `BEGIN_WITH` and `BEGIN_AFTER` filters allow restart on an object type boundary. Appropriate filter values are returned by the `FETCH_XML_CLOB` procedure.

Filters on heterogeneous objects provide default values for filters on object types within the collection. You can override this default for a particular object type by specifying the appropriate filter for the specific object type path. For example, for `SCHEMA_EXPORT` the `NAME` filter specifies the schema to be fetched including all the tables in the schema, but you can further restrict this set of tables by supplying a `NAME_EXPR` filter explicitly for the `TABLE` object type path. [Table 110-19](#) lists valid object type path names for the major heterogeneous object types along with an explanation of the scope of each path name. (The same information is available in the following catalog views:

`DATABASE_EXPORT_OBJECTS`, `SCHEMA_EXPORT_OBJECTS`, and `TABLE_EXPORT_OBJECTS`.) See [Table 110-18](#) for filters defined for each path name. These path names are valid in the `INCLUDE_PATH_EXPR` and `EXCLUDE_PATH_EXPR` filters. Path names marked with an asterisk (\*) are *only* valid in those filters; they cannot be used as values of the `SET_FILTER` `object_type_path` parameter.

**Table 110-19 Object Type Path Names for Heterogeneous Object Types**

| Heterogeneous Type | Path Name (*=valid only in xxx_PATH_EXPR) | Scope                                             |
|--------------------|-------------------------------------------|---------------------------------------------------|
| TABLE_EXPORT       | AUDIT_OBJ                                 | Object audits on the selected tables              |
| TABLE_EXPORT       | COMMENT                                   | Table and column comments for the selected tables |

**Table 110-19 (Cont.) Object Type Path Names for Heterogeneous Object Types**

| Heterogeneous Type | Path Name (*=valid only in xxx_PATH_EXPR) | Scope                                                                                                 |
|--------------------|-------------------------------------------|-------------------------------------------------------------------------------------------------------|
| TABLE_EXPORT       | CONSTRAINT                                | Constraints (including referential constraints) on the selected tables                                |
| TABLE_EXPORT       | *GRANT                                    | Object grants on the selected tables                                                                  |

| TABLE_EXPORT       | TRIGGER                                   | Triggers on the selected tables                                                                       |
| SCHEMA_EXPORT      | ASSOCIATION                               | Statistics type associations for objects in the selected schemas                                      |
| SCHEMA_EXPORT      | AUDIT_OBJ                                 | Audits on all objects in the selected schemas                                                         |
| SCHEMA_EXPORT      | CLUSTER                                   | Clusters in the selected schemas and their indexes                                                    |
| SCHEMA_EXPORT      | COMMENT                                   | Comments on all objects in the selected schemas                                                       |
| SCHEMA_EXPORT      | CONSTRAINT                                | Constraints (including referential constraints) on all objects in the selected schemas                |
| SCHEMA_EXPORT      | DB_LINK                                   | Private database links in the selected schemas                                                        |
| SCHEMA_EXPORT      | DEFAULT_ROLE                              | Default roles granted to users associated with the selected schemas                                   |
| SCHEMA_EXPORT      | DIMENSION                                 | Dimensions in the selected schemas                                                                    |
| SCHEMA_EXPORT      | FUNCTION                                  | Functions in the selected schemas and their dependent grants and audits                               |
| SCHEMA_EXPORT      | *GRANT                                    | Grants on objects in the selected schemas                                                             |
| SCHEMA_EXPORT      | INDEX                                     | Indexes (including domain indexes) on tables and clusters in the selected schemas                     |
| SCHEMA_EXPORT      | INDEXTYPE                                 | Indextypes in the selected schemas and their dependent grants and audits                              |
| SCHEMA_EXPORT      | JAVA_SOURCE                               | Java sources in the selected schemas and their dependent grants and audits                            |
| SCHEMA_EXPORT      | JOB                                       | Jobs in the selected schemas                                                                          |
| SCHEMA_EXPORT      | LIBRARY                                   | External procedure libraries in the selected schemas                                                  |
| SCHEMA_EXPORT      | MATERIALIZED_VIEW                         | Materialized views in the selected schemas                                                            |
| SCHEMA_EXPORT      | MATERIALIZED_VIEW_LOG                     | Materialized view logs on tables in the selected schemas                                              |
| SCHEMA_EXPORT      | OBJECT_GRANT                              | Grants on objects in the selected schemas                                                             |
| SCHEMA_EXPORT      | OPERATOR                                  | Operators in the selected schemas and their dependent grants and audits                               |
| SCHEMA_EXPORT      | PACKAGE                                   | Packages (both specification and body) in the selected schemas, and their dependent grants and audits |
| SCHEMA_EXPORT      | PACKAGE_BODY                              | Package bodies in the selected schemas                                                                |
| SCHEMA_EXPORT      | PACKAGE_SPEC                              | Package specifications in the selected schemas                                                        |

**Table 110-19 (Cont.) Object Type Path Names for Heterogeneous Object Types**

| Heterogeneous Type | Path Name (*=valid only in xxx_PATH_EXPR) | Scope                                                                                                                                        |
|--------------------|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| SCHEMA_EXPORT      | PASSWORD_HISTORY                          | The password history for users associated with the selected schemas                                                                          |
| SCHEMA_EXPORT      | PROCEDURE                                 | Procedures in the selected schemas and their dependent grants and audits                                                                     |
| SCHEMA_EXPORT      | REF_CONSTRAINT                            | Referential (foreign key) constraints on tables in the selected schemas                                                                      |
| SCHEMA_EXPORT      | REFRESH_GROUP                             | Refresh groups in the selected schemas                                                                                                       |
| SCHEMA_EXPORT      | SEQUENCE                                  | Sequences in the selected schemas and their dependent grants and audits                                                                      |
| SCHEMA_EXPORT      | STATISTICS                                | Statistics on tables and indexes in the selected schemas                                                                                     |
| SCHEMA_EXPORT      | SYNONYM                                   | Private synonyms in the selected schemas                                                                                                     |
| SCHEMA_EXPORT      | TABLE                                     | Tables in the selected schemas and their dependent objects (indexes, constraints, triggers, grants, audits, comments, table data, and so on) |
| SCHEMA_EXPORT      | TABLE_DATA                                | Row data for tables in the selected schemas                                                                                                  |
| SCHEMA_EXPORT      | TABLESPACE_QUOTA                          | Tablespace quota granted to users associated with the selected schemas                                                                       |
| SCHEMA_EXPORT      | TRIGGER                                   | Triggers on tables in the selected schemas                                                                                                   |
| SCHEMA_EXPORT      | XS_SECURITY_CLASS                         | Oracle Real Application Security (RAS) security classes                                                                                      |
| SCHEMA_EXPORT      | XS_DATA_SECURITY                          | Oracle Real Application Security (RAS) data security policies                                                                                |
| SCHEMA_EXPORT      | XS_ACL                                    | Oracle Real Application Security (RAS) access control lists (ACLs)                                                                           |
| SCHEMA_EXPORT      | TYPE                                      | Types (both specification and body) in the selected schemas, and their dependent grants and audits                                           |
| SCHEMA_EXPORT      | TYPE_BODY                                 | Type bodies in the selected schemas                                                                                                          |
| SCHEMA_EXPORT      | TYPE_SPEC                                 | Type specifications in the selected schemas                                                                                                  |
| SCHEMA_EXPORT      | USER                                      | User definitions for users associated with the selected schemas                                                                              |
| SCHEMA_EXPORT      | VIEW                                      | Views in the selected schemas and their dependent objects (grants, constraints, comments, audits)                                            |
| DATABASE_EXPORT    | ASSOCIATION                               | Statistics type associations for objects in the database                                                                                     |
| DATABASE_EXPORT    | AUDIT                                     | Audits of SQL statements                                                                                                                     |
| DATABASE_EXPORT    | AUDIT_OBJ                                 | Audits on all objects in the database                                                                                                        |
| DATABASE_EXPORT    | CLUSTER                                   | Clusters and their indexes                                                                                                                   |
| DATABASE_EXPORT    | COMMENT                                   | Comments on all objects                                                                                                                      |
| DATABASE_EXPORT    | CONSTRAINT                                | Constraints (including referential constraints)                                                                                              |
| DATABASE_EXPORT    | CONTEXT                                   | Application contexts                                                                                                                         |
| DATABASE_EXPORT    | DB_LINK                                   | Private and public database links                                                                                                            |
| DATABASE_EXPORT    | DEFAULT_ROLE                              | Default roles granted to users in the database                                                                                               |

**Table 110-19 (Cont.) Object Type Path Names for Heterogeneous Object Types**

| Heterogeneous Type | Path Name (*=valid only in xxx_PATH_EXPR) | Scope                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATABASE_EXPORT    | FGA_POLICY                                | Fine-grained audit policies                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DATABASE_EXPORT    | FUNCTION                                  | Functions                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DATABASE_EXPORT    | * GRANT                                   | Object and system grants                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| DATABASE_EXPORT    | INDEX                                     | Indexes (including domain indexes) on tables and clusters                                                                                                                                                                                                                                                                                                                                                                                                    |
| DATABASE_EXPORT    | INDEXTYPE                                 | Indextypes and their dependent grants and audits                                                                                                                                                                                                                                                                                                                                                                                                             |
| DATABASE_EXPORT    | JAVA_SOURCE                               | Java sources and their dependent grants and audits                                                                                                                                                                                                                                                                                                                                                                                                           |
| DATABASE_EXPORT    | JOB                                       | Jobs                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DATABASE_EXPORT    | LIBRARY                                   | External procedure libraries                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DATABASE_EXPORT    | MATERIALIZED_VIEW                         | Materialized views                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DATABASE_EXPORT    | MATERIALIZED_VIEW_LOG                     | Materialized view logs                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DATABASE_EXPORT    | OBJECT_GRANT                              | All object grants in the database                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DATABASE_EXPORT    | OPERATOR                                  | Operators and their dependent grants and audits                                                                                                                                                                                                                                                                                                                                                                                                              |
| DATABASE_EXPORT    | PACKAGE                                   | Packages (both specification and body) and their dependent grants and audits                                                                                                                                                                                                                                                                                                                                                                                 |
| DATABASE_EXPORT    | PACKAGE_BODY                              | Package bodies                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DATABASE_EXPORT    | PACKAGE_SPEC                              | Package specifications                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DATABASE_EXPORT    | PASSWORD_HISTORY                          | Password histories for database users                                                                                                                                                                                                                                                                                                                                                                                                                        |

| DATABASE_EXPORT    | ROLE_GRANT                                | Role grants to users in the database                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DATABASE_EXPORT    | ROLLBACK_SEGMENT                          | Rollback segments                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DATABASE_EXPORT    | *SCHEMA (named object)                    | Database schemas including for each schema all related and dependent objects: user definitions and their attributes (default roles, role grants, tablespace quotas, and so on), objects in the schema (tables, view, packages, types, and so on), and their dependent objects (grants, audits, indexes, constraints, and so on). The NAME and NAME_EXPR filters can be used with this object type path name to designate the database schemas to be fetched. |

**Table 110-19 (Cont.) Object Type Path Names for Heterogeneous Object Types**

| Heterogeneous Type | Path Name (*=valid only in xxx_PATH_EXPR) | Scope                                                                                                                |
|--------------------|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| DATABASE_EXPORT    | SEQUENCE                                  | Sequences                                                                                                            |
| DATABASE_EXPORT    | STATISTICS                                | Statistics on tables and indexes                                                                                     |
| DATABASE_EXPORT    | SYNONYM                                   | Public and private synonyms                                                                                          |
| DATABASE_EXPORT    | SYSTEM_GRANT                              | System privilege grants                                                                                              |
| DATABASE_EXPORT    | TABLE                                     | Tables and their dependent objects (indexes, constraints, triggers, grants, audits, comments, table data, and so on) |
| DATABASE_EXPORT    | TABLE_DATA                                | Row data for all tables                                                                                              |

#### Exceptions

- **INVALID\_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- **INVALID\_OPERATION.** SET\_FILTER was called after the first call to FETCH\_xxx for the OPEN context. After the first call to FETCH\_xxx is made, no further calls to SET\_FILTER are permitted.
- **INCONSISTENT\_ARGS.** The arguments are inconsistent. Possible inconsistencies include the following:
  - The filter name is not valid for the object type associated with the OPEN context.
  - The filter name is not valid for the object\_type\_path.
  - The object\_type\_path is not part of the collection designated by handle .
  - The filter value is the wrong datatype.

## 110.6.12 SET\_PARSE\_ITEM Procedure

This procedure is used for both retrieval and submission. This procedure enables output parsing and specifies an object attribute to be parsed and returned.

### See Also:

### Syntax

The following syntax applies when SET\_PARSE\_ITEM is used for object retrieval:

```
DBMS_METADATA.SET_PARSE_ITEM (
    handle          IN  NUMBER,
    name            IN  VARCHAR2,
    object_type     IN  VARCHAR2 DEFAULT NULL);
```

The following syntax applies when SET\_PARSE\_ITEM is used for XML submission:

```
DBMS_METADATA.SET_PARSE_ITEM (
    handle          IN  NUMBER,
    name            IN  VARCHAR2);
```

### Parameters

**Table 110-20 SET\_PARSE\_ITEM Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle returned from OPEN (or OPENW).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| name        | The name of the object attribute to be parsed and returned. See <a href="#">Table 110-21</a> for the attribute object type, name, and meaning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| object_type | <p>Designates the object type to which the parse item applies (this is an object type name, not a path name). By default, the parse item applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, behavior can be either of the following:</p> <ul style="list-style-type: none"> <li>• If object_type is omitted, then the parse item applies to all object types within the heterogeneous collection</li> <li>• If object_type is specified, then the parse item only applies to that specific object type within the collection</li> </ul> <p>This parameter only applies when SET_PARSE_ITEM is used for object retrieval.</p> |

[Table 110-21](#) describes the object type, name, and meaning of the items available in the SET\_PARSE\_ITEM procedure.

Because new items are occasionally added, you can query the `DBMS_METADATA_PARSE_ITEMS` view to see a complete list of valid parse items or to find valid parse items for a specific object type.

**Table 110-21 SET\_PARSE\_ITEM: Parse Items**

| Object Type                                                          | Name               | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All objects                                                          | VERB               | <p>If <code>FETCH_XML_CLOB</code> is called, no value is returned.</p> <p>If <code>FETCH_DDL</code> is called, then for every row in the <code>sys.ku\$_ddls</code> nested table returned by <code>FETCH_DDL</code> the verb in the corresponding <code>ddlText</code> is returned. If the <code>ddlText</code> is a SQL DDL statement, then the SQL verb (for example, <code>CREATE</code>, <code>GRANT</code>, <code>AUDIT</code>) is returned. If the <code>ddlText</code> is a procedure call (for example, <code>DBMS_AQADM.CREATE_QUEUE_TABLE()</code>) then the <code>package.procedure-name</code> is returned.</p> |
| All objects                                                          | OBJECT_TYPE        | <p>If <code>FETCH_XML_CLOB</code> is called, an object type name from <a href="#">Table 110-12</a> is returned.</p> <p>If <code>FETCH_DDL</code> is called and the <code>ddlText</code> is a SQL DDL statement whose verb is <code>CREATE</code> or <code>ALTER</code>, the object type as used in the DDL statement is returned (for example, <code>TABLE</code>, <code>PACKAGE_BODY</code>, and so on). Otherwise, an object type name from <a href="#">Table 110-12</a> is returned.</p>                                                                                                                                 |
| Schema objects                                                       | SCHEMA             | The object schema is returned. If the object is not a schema object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Named objects                                                        | NAME               | The object name is returned. If the object is not a named object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| TABLE,<br>TABLE_DATA,<br>INDEX                                       | TABSPACE           | The name of the object's tablespace or, if the object is a partitioned table, the default tablespace is returned. For a <code>TABLE_DATA</code> object, this is always the tablespace where the rows are stored.                                                                                                                                                                                                                                                                                                                                                                                                            |
| TRIGGER                                                              | ENABLE             | If the trigger is enabled, <code>ENABLE</code> is returned. If the trigger is disabled, <code>DISABLE</code> is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| OBJECT_GRANT,<br>TABLESPACE_QUOTA                                    | GRANTOR            | The grantor is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Dependent objects<br>(including domain<br>index secondary<br>tables) | BASE_OBJECT_NAME   | The name of the base object is returned. If the object is not a dependent object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Dependent objects<br>(including domain<br>index secondary<br>tables) | BASE_OBJECT_SCHEMA | The schema of the base object is returned. If the object is not a dependent object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Dependent objects<br>(including domain<br>index secondary<br>tables) | BASE_OBJECT_TYPE   | The object type of the base object is returned. If the object is not a dependent object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Granted objects                                                      | GRANTEE            | The grantee is returned. If the object is not a granted object, no value is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Usage Notes

These notes apply when using `SET_PARSE_ITEM` to retrieve objects.

By default, the `FETCH_xxx` routines return an object's metadata as XML or creation DDL. By calling `SET_PARSE_ITEM` you can request that individual attributes of the object be returned as well.

You can call `SET_PARSE_ITEM` multiple times to ask for multiple items to be parsed and returned. Parsed items are returned in the `sys.ku$_parsed_items` nested table.

For `TABLE_DATA` objects, the following parse item return values are of interest:

| If Object Is         | NAME, SCHEMA               | BASE_OBJECT_NAME,<br>BASE_OBJECT_SCHEMA                                  |
|----------------------|----------------------------|--------------------------------------------------------------------------|
| nonpartitioned table | table name, schema         | table name, schema                                                       |
| table partition      | partition name, schema     | table name, schema                                                       |
| nested table         | storage table name, schema | name and schema of top-level table ( <i>not</i> the parent nested table) |

Tables are not usually thought of as dependent objects. However, secondary tables for domain indexes are dependent on the domain indexes. Consequently, the `BASE_OBJECT_NAME`, `BASE_OBJECT_SCHEMA` and `BASE_OBJECT_TYPE` parse items for secondary `TABLE` objects return the name, schema, and type of the domain index.

#### See Also:

- ["FETCH\\_xxx Functions and Procedures"](#)
- *Oracle Database Utilities* for more information about using the metadata APIs.

By default, the `CONVERT` and `PUT` procedures simply transform an object's XML metadata to DDL. By calling `SET_PARSE_ITEM` you can request that individual attributes of the object be returned as well.

#### Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OPERATION`. `SET_PARSE_ITEM` was called after the first call to `FETCH_xxx` for the `OPEN` context. After the first call to `FETCH_xxx` is made, no further calls to `SET_PARSE_ITEM` are permitted.
- `INCONSISTENT_ARGS`. The attribute `name` is not valid for the object type associated with the `OPEN` context.

## 110.6.13 SET\_TRANSFORM\_PARAM and SET\_REMAP\_PARAM Procedures

These procedures are used for both retrieval and submission. `SET_TRANSFORM_PARAM` and `SET_REMAP_PARAM` specify parameters to the XSLT stylesheet identified by `transform_handle`.

Use them to modify or customize the output of the transform.

## Syntax

```
DBMS_METADATA.SET_TRANSFORM_PARAM (
    transform_handle    IN NUMBER,
    name                IN VARCHAR2,
    value               IN VARCHAR2,
    object_type         IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_TRANSFORM_PARAM (
    transform_handle    IN NUMBER,
    name                IN VARCHAR2,
    value               IN BOOLEAN DEFAULT TRUE,
    object_type         IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_TRANSFORM_PARAM (
    transform_handle    IN NUMBER,
    name                IN VARCHAR2,
    value               IN NUMBER,
    object_type         IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_REMAP_PARAM (
    transform_handle    IN NUMBER,
    name                IN VARCHAR2,
    old_value           IN VARCHAR2,
    new_value           IN VARCHAR2,
    object_type         IN VARCHAR2 DEFAULT NULL);
```

## Parameters

[Table 110-22](#) describes the parameters for the `SET_TRANSFORM_PARAM` and `SET_REMAP_PARAM` procedures.

Because new parameters are occasionally added, you might want to query the `DBMS_METADATA_TRANSFORM_PARAMS` view to see all the valid transform parameters for each transform or to find valid transform parameters for specific object types.

**Table 110-22 SET\_TRANSFORM\_PARAM and SET\_REMAP\_PARAM Parameters**

| Parameters                    | Description                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>transform_handle</code> | <p>Either (1) the handle returned from <code>ADD_TRANSFORM</code>, or (2) the enumerated constant <code>SESSION_TRANSFORM</code> that designates the DDL transform for the whole session.</p> <p>Note that the handle returned by <code>OPEN</code> is not a valid transform handle.</p> <p>For <code>SET_REMAP_PARAM</code>, the transform handle must designate the <code>MODIFY</code> transform.</p> |

**Table 110-22 (Cont.) SET\_TRANSFORM\_PARAM and SET\_REMAP\_PARAM Parameters**

| Parameters  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name        | <p>The name of the transform parameter.</p> <p>For descriptions of the parameters available for each transform on the SET_TRANSFORM_PARAM procedure, see the following:</p> <p><a href="#">Table 110-23</a> - DDL transform</p> <p><a href="#">Table 110-24</a> - MODIFY transform</p> <p><a href="#">Table 110-26</a> - SXML transform</p> <p><a href="#">Table 110-27</a> - MODIFYXML transform</p> <p><a href="#">Table 110-28</a> - SXMLDDL transform</p> <p>For descriptions of the parameters available for the MODIFY transform on the SET_REMAP_PARAM procedure, see <a href="#">Table 110-25</a>.</p> <p>For descriptions of the parameters available for the ALTERXML transform, see <a href="#">Table 110-4</a>.</p> |
| value       | The value of the transform. This parameter is valid only for SET_TRANSFORM_PARAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| old_value   | The old value for the remapping. This parameter is valid only for SET_REMAP_PARAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| new_value   | The new value for the remapping. This parameter is valid only for SET_REMAP_PARAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| object_type | <p>Designates the object type to which the transform or remap parameter applies. By default, it applies to the same object type as the transform. In cases where the transform applies to all object types within a heterogeneous collection, the following apply:</p> <ul style="list-style-type: none"> <li>• If object_type is omitted, the parameter applies to all applicable object types within the heterogeneous collection.</li> <li>• If object_type is specified, the parameter only applies to that object type.</li> </ul> <p>This allows a caller who has added a transform to a heterogeneous collection to specify different transform parameters for different object types within the collection.</p>         |

[Table 110-23](#) describes the object type, name, datatype, and meaning of the parameters for the DDL transform in the SET\_TRANSFORM\_PARAM procedure.

**Table 110-23 SET\_TRANSFORM\_PARAM: Transform Parameters for the DDL Transform**

| Object Type                                                                               | Name             | Datatype | Meaning                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------------------------------------------|------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USER, TABLE, CLUSTER, VIEW, MATERIALIZED_VIEW PROCEDURE, FUNCTION, PACKAGE, TYPE, TRIGGER | COLLATION_CLAUSE | Text     | <p>There are three possible values:</p> <ul style="list-style-type: none"> <li>• NEVER — Collation clauses are never generated.</li> <li>• ALWAYS — Collation clauses are always generated.</li> <li>• NON_DEFAULT — Collation clauses other than USING_NLS_COMP are generated.</li> </ul> |

**Table 110-23 (Cont.) SET\_TRANSFORM\_PARAM: Transform Parameters for the DDL Transform**

| Object Type       | Name                          | Datatype | Meaning                                                                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE             | OMIT_ENCRYPTION_CLAUSE        | BOOLEAN  | <p>If set to Y, directs Data Pump to suppress column encryption clauses. Columns encrypted in the source database are not encrypted in imported tables. Defaults to N.</p> <p>If set to N, directs Data Pump to create column encryption clauses, as in the source database.</p>                                                |
| TABLE             | DWCS_CVT_IOTS                 | BOOLEAN  | <p>If set to Y, directs Data Pump to transform Index Organized tables to heap organized tables by suppressing the ORGANIZATION INDEX clause when creating the table. Defaults to N.</p> <p>If set to N, the generated DDL retains the table characteristics of the source object.</p>                                           |
| TABLE, CONSTRAINT | DWCS_CVT_CONSTRAINTS          | BOOLEAN  | <p>If set to Y, directs Data Pump to create pk/fk/uk constraints as disabled. Defaults to N.</p> <p>If set to N, directs Data Pump to create pk/fk/uk constraints based on the source database status.</p>                                                                                                                      |
| TABLE, CONSTRAINT | CONSTRAINT_USE_DEFAULT_IN_DEX | BOOLEAN  | <p>This transform parameter affects the generation of index relating the pk/uk constraint. If set to Y, forces the name of an index automatically created to enforce the constraint to be identical to the constraint name. Defaults to N.</p> <p>If set to N, the index is created as it was named on the source database.</p> |
| TABLE, CONSTRAINT | CONSTRAINT_NAME_FROM_INDEX    | BOOLEAN  | <p>This transform parameter affects the generation of pk/uk constraints which reference user created indexes. If set to Y, forces the name of the constraint to match the name of the index. Defaults to N.</p> <p>If set to N, the constraint is created as it was named on the source database.</p>                           |
| All objects       | PRETTY                        | BOOLEAN  | <p>If TRUE, format the output with indentation and line feeds. Defaults to TRUE.</p>                                                                                                                                                                                                                                            |
| All objects       | SQLTERMINATOR                 | BOOLEAN  | <p>If TRUE, append a SQL terminator (; or /) to each DDL statement. Defaults to FALSE.</p>                                                                                                                                                                                                                                      |
| TABLE             | CONSTRAINTS                   | BOOLEAN  | <p>If TRUE, include all non-referential table constraints in the DDL. If FALSE, omit them. Defaults to TRUE.</p>                                                                                                                                                                                                                |
| TABLE             | REF_CONSTRAINTS               | BOOLEAN  | <p>If TRUE, include all referential constraints (foreign keys) in the DDL. If FALSE, omit them. Defaults to TRUE.</p>                                                                                                                                                                                                           |

**Table 110-23 (Cont.) SET\_TRANSFORM\_PARAM: Transform Parameters for the DDL Transform**

| Object Type                                                                                                                                                                                                                                                                  | Name                 | Datatype | Meaning                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE                                                                                                                                                                                                                                                                        | CONSTRAINTS_AS_ALTER | BOOLEAN  | If TRUE, include table constraints as separate ALTER TABLE (and, if necessary, CREATE INDEX) statements. If FALSE, specify table constraints as part of the CREATE TABLE statement. Defaults to FALSE. Requires that CONSTRAINTS be TRUE. |
| <div>  <b>Note:</b><br/>           The CONSTRAINTS_AS_ALTER parameter has no effect when an index and a constraint are created for a table in two separate DDL statements.         </div> |                      |          |                                                                                                                                                                                                                                           |
| TABLE, TYPE                                                                                                                                                                                                                                                                  | OID                  | BOOLEAN  | If TRUE, include the Object ID (OID) clause in the DDL. If FALSE, omit it. Defaults to FALSE.                                                                                                                                             |
| TABLE                                                                                                                                                                                                                                                                        | SIZE_BYTE_KEYWORD    | BOOLEAN  | If TRUE, include the BYTE keyword as part of the size specification of CHAR and VARCHAR2 columns that use byte semantics. If FALSE, omit the keyword. Defaults to FALSE.                                                                  |
| TABLE, INDEX                                                                                                                                                                                                                                                                 | PARTITIONING         | BOOLEAN  | If TRUE, include partitioning clauses in the DDL. If FALSE, omit them. Defaults to TRUE.                                                                                                                                                  |
| INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE, TABLESPACE                                                                                                                                                                                                              | SEGMENT_ATTRIBUTES   | BOOLEAN  | If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the DDL. If FALSE, omit them. Defaults to TRUE.                                                                             |
| INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE                                                                                                                                                                                                                          | STORAGE              | BOOLEAN  | If TRUE, include storage clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.                                                                                                             |
| INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE                                                                                                                                                                                                                          | TABLESPACE           | BOOLEAN  | If TRUE, include tablespace clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.                                                                                                          |
| TYPE, PACKAGE                                                                                                                                                                                                                                                                | SPECIFICATION        | BOOLEAN  | If TRUE, include the type or package specification in the DDL. If FALSE, omit it. Defaults to TRUE.                                                                                                                                       |
| TYPE, PACKAGE                                                                                                                                                                                                                                                                | BODY                 | BOOLEAN  | If TRUE, include the type body or package body in the DDL. If FALSE, omit it. Defaults to TRUE.                                                                                                                                           |

**Table 110-23 (Cont.) SET\_TRANSFORM\_PARAM: Transform Parameters for the DDL Transform**

| Object Type                                               | Name        | Datatype | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------|-------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VIEW                                                      | FORCE       | BOOLEAN  | If TRUE, use the <code>FORCE</code> keyword in the <code>CREATE VIEW</code> statement. If FALSE, do not use the <code>FORCE</code> keyword in the <code>CREATE VIEW</code> statement. Defaults to TRUE.                                                                                                                                                                                                                                                                                                                                        |
| OUTLINE                                                   | INSERT      | BOOLEAN  | If TRUE, include the <code>INSERT</code> statements into the <code>OL\$</code> dictionary tables that will create the outline and its hints. If FALSE, omit a <code>CREATE OUTLINE</code> statement. Defaults to FALSE.<br><br>Note: This object type is being deprecated.                                                                                                                                                                                                                                                                     |
| All objects                                               | DEFAULT     | BOOLEAN  | Calling <code>SET_TRANSFORM_PARAM</code> with this parameter set to TRUE has the effect of resetting all parameters for the transform to their default values. Setting this FALSE has no effect. There is no default.                                                                                                                                                                                                                                                                                                                          |
| All objects                                               | INHERIT     | BOOLEAN  | If TRUE, inherits session-level parameters. Defaults to FALSE. If an application calls <code>ADD_TRANSFORM</code> to add the DDL transform, then by default the only transform parameters that apply are those explicitly set for that transform handle. This has no effect if the transform handle is the session transform handle.                                                                                                                                                                                                           |
| ROLE                                                      | REVOKE_FROM | Text     | The name of a user from whom the role must be revoked. If this is a non-null string and if the <code>CREATE ROLE</code> statement grants you the role, a <code>REVOKE</code> statement is included in the DDL after the <code>CREATE ROLE</code> statement.<br><br>Note: When you issue a <code>CREATE ROLE</code> statement, Oracle may grant you the role. You can use this transform parameter to undo the grant.<br><br>Defaults to null string.                                                                                           |
| TABLESPACE                                                | REUSE       | BOOLEAN  | If TRUE, include the <code>REUSE</code> parameter for datafiles in a tablespace to indicate that existing files can be reused. If FALSE, omit the <code>REUSE</code> parameter.<br><br>Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                      |
| CLUSTER, INDEX,<br>ROLLBACK_SEGMENT,<br>TABLE, TABLESPACE | PCTSPACE    | NUMBER   | A number representing the percentage by which space allocation for the object type is to be modified. The value is the number of one-hundredths of the current allocation. For example, 100 means 100%.<br><br>If the object type is <code>TABLESPACE</code> , the following size values are affected:<br>- in file specifications, the value of <code>SIZE</code><br>- <code>MINIMUM EXTENT</code><br>- <code>EXTENT MANAGEMENT LOCAL UNIFORM SIZE</code><br>For other object types, <code>INITIAL</code> and <code>NEXT</code> are affected. |

**Table 110-23 (Cont.) SET\_TRANSFORM\_PARAM: Transform Parameters for the DDL Transform**

| Object Type | Name                     | Datatype | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE       | LOB_STORAGE              | Text     | <p>Specifies the storage type to use for LOB segments. The options are as follows:</p> <ul style="list-style-type: none"> <li>• SECUREFILE - LOB storage is returned as SECUREFILE</li> <li>• BASICFILE - LOB storage is returned as BASICFILE</li> <li>• DEFAULT - The keyword (SECUREFILE or BASICFILE) is omitted in the LOB STORE AS clause.</li> <li>• NO_CHANGE - LOB segments are created with the same storage they had in the source database. This is the default.</li> </ul> <p>Specifying this transform changes the LOB storage for all tables in the job, including tables that provide storage for materialized views.</p> |
| TABLE       | TABLE_COMPRESSION_CLAUSE | Text     | <p>Specifies a table compression clause (for example, COMPRESS BASIC) to use when the table is created.</p> <p>Specify NONE to omit the table compression clause. The table will have the default compression for the tablespace.</p> <p>Specifying this transform changes the compression type for all tables in the job, including tables that provide storage for materialized views.</p>                                                                                                                                                                                                                                              |

Table 110-24 describes the object type, name, datatype, and meaning of the parameters for the MODIFY transform in the SET\_TRANSFORM\_PARAM procedure.

**Table 110-24 SET\_TRANSFORM\_PARAM: Transform Parameters for the MODIFY Transform**

| Object Type | Name       | Datatype | Meaning                                                                                                                                                                                                                                                          |
|-------------|------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All objects | OBJECT_ROW | NUMBER   | <p>A number designating the object row for an object. The object in the document that corresponds to this number will be copied to the output document.</p> <p>This parameter is additive.</p> <p>By default, all objects are copied to the output document.</p> |

Table 110-25 describes the object type, name, datatype, and meaning of the parameters for the MODIFY transform in the SET\_REMAP\_PARAM procedure.

**Table 110-25 SET\_REMAP\_PARAM: Transform Parameters for the MODIFY Transform**

| Object Type                                                                                                                        | Name             | Datatype | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|-----------------------------------------------------------------|--------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG | TABLESPACE         | Boolean  | If TRUE, include tablespace clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.                                         |
| TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG | STORAGE            | Boolean  | If TRUE, include storage clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.                                            |
| TABLE                                                           | REF_CONSTRAINTS    | Boolean  | If TRUE, include all referential constraints (foreign keys) in the DDL. If FALSE, omit them. Defaults to TRUE.                                                           |
| INDEX                                                           | PRESERVE_LOCAL     | Boolean  | If PARTITIONING is FALSE and PRESERVE_LOCAL is TRUE and the index is a locally partitioned index, include the LOCAL keyword in the DDL. Defaults to FALSE.               |
| TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG | SEGMENT_ATTRIBUTES | Boolean  | If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the DDL. If FALSE, omit them. Defaults to TRUE.            |
| TABLESPACE                                                      | REUSE              | Boolean  | If TRUE, include the REUSE parameter for datafiles in a tablespace to indicate that existing files can be reused. If FALSE, omit the REUSE parameter. Defaults to FALSE. |
| TABLE, INDEX                                                    | PARTITIONING       | Boolean  | If TRUE, include partitioning clauses in the DDL. If FALSE, omit them. Defaults to TRUE.                                                                                 |
| TABLE                                                           | CONSTRAINTS        | Boolean  | If TRUE, include all non-referential table constraints in the output SXML. If FALSE, omit them. Defaults to TRUE.                                                        |

### Exceptions

- **INVALID\_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- **INVALID\_OPERATION.** Either SET\_TRANSFORM\_PARAM or SET\_REMAP\_PARAM was called after the first call to FETCH\_xxx for the OPEN context. After the first call to FETCH\_xxx is made, no further calls to SET\_TRANSFORM\_PARAM or SET\_REMAP\_PARAM are permitted.
- **INCONSISTENT\_ARGS.** The arguments are inconsistent. This can mean the following:
  - The transform parameter name is not valid for the object type associated with the OPEN context or for the transform associated with the transform handle.
  - The transform applies to all object types in a heterogeneous collection, but object\_type is not part of the collection.

## Usage Notes

XSLT allows parameters to be passed to stylesheets. You call `SET_TRANSFORM_PARAM` or `SET_REMAP_PARAM` to specify the value of a parameter to be passed to the stylesheet identified by `transform_handle`.

Normally, if you call `SET_TRANSFORM_PARAMETER` multiple times for the same parameter name, each call overrides the prior call. For example, the following sequence simply sets the `STORAGE` transform parameter to `TRUE`.

```
SET_TRANSFORM_PARAM(tr_handle, 'STORAGE', false);  
SET_TRANSFORM_PARAM(tr_handle, 'STORAGE', true);
```

However, some transform parameters are additive which means that all specified parameter values are applied to the document, not just the last one. For example, the `OBJECT_ROW` parameter to the `MODIFY` transform is additive. If you specify the following, then both specified rows are copied to the output document.

```
SET_TRANSFORM_PARAM(tr_handle, 'OBJECT_ROW', 5);  
SET_TRANSFORM_PARAM(tr_handle, 'OBJECT_ROW', 8);
```

The `REMAP_TABLESPACE` parameter is also additive. If you specify the following, then tablespaces `TBS1` and `TBS3` are changed to `TBS2` and `TBS4`, respectively.

```
SET_REMAP_PARAM(tr_handle, 'REMAP_TABLESPACE', 'TBS1', 'TBS2');  
SET_REMAP_PARAM(tr_handle, 'REMAP_TABLESPACE', 'TBS3', 'TBS4');
```

The order in which the transformations are performed is undefined. For example, if you specify the following, the result is undefined.

```
SET_REMAP_PARAM(tr_handle, 'REMAP_TABLESPACE', 'TBS1', 'TBS2');  
SET_REMAP_PARAM(tr_handle, 'REMAP_TABLESPACE', 'TBS2', 'TBS3');
```

### Note:

The number of remap parameters that can be specified for a `MODIFY` transform is limited to ten. That is, you can specify up to ten `REMAP_DATAFILE` parameters, up to ten `REMAP_SCHEMA` parameters and so on. Additional instances are ignored. To work around this, you can perform another `DBMS_METADATA.ADD_TRANSFORM` and specify additional remap parameters.

The `GET_DDL`, `GET_DEPENDENT_DDL`, and `GET_GRANTED_DDL` functions allow the casual browser to extract the creation DDL for an object. So that you can specify transform parameters, this package defines an enumerated constant `SESSION_TRANSFORM` as the handle of the DDL transform at the session level. You can call `SET_TRANSFORM_PARAM` using `DBMS_METADATA.SESSION_TRANSFORM` as the transform handle to set transform parameters for the whole session. `GET_DDL`, `GET_DEPENDENT_DDL`, and `GET_GRANTED_DDL` inherit these parameters when they invoke the DDL transform.

**Note:**

The enumerated constant must be prefixed with the package name  
`DBMS_METADATA.SESSION_TRANSFORM`.

# DBMS\_METADATA\_DIFF

The `DBMS_METADATA_DIFF` package contains the interfaces for comparing two metadata documents in SXML format.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Browsing APIs for Fetching and Comparing Objects](#)
- [Summary of DBMS\\_METADATA\\_DIFF Subprograms](#)

## See Also:

*Oracle Database Utilities* for more information and for examples of using the `DBMS_METADATA_DIFF` package.

## 111.1 DBMS\_METADATA\_DIFF Overview

You can use the interfaces contained in the `DBMS_METADATA_DIFF` package to compare two metadata documents in SXML format.

The result of the comparison is an SXML difference document. This document can be converted to other formats using the `DBMS_METADATA` submit interface and the `CONVERT` API.

## 111.2 DBMS\_METADATA\_DIFF Security Model

The browsing interface of the `DBMS_METADATA_DIFF` package actually uses the `DBMS_METADATA` package to fetch the metadata to be compared. Therefore, the security model used for `DBMS_METADATA` also applies to `DBMS_METADATA_DIFF`. (Note, however, that `DBMS_METADATA_DIFF` does not support all object types.)

## See Also:

[DBMS\\_METADATA](#) for information about the `DBMS_METADATA` security model

## 111.3 DBMS\_METADATA\_DIFF — Browsing APIs for Fetching and Comparing Objects

These functions allow you to compare the metadata for two objects with a single call.

### Syntax

```
DBMS_METADATA_DIFF.COMPARE_SXML(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

```
DBMS_METADATA_DIFF.COMPARE_ALTER(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

```
DBMS_METADATA_DIFF.COMPARE_ALTER_XML(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

### Parameters

**Table 111-1 COMPARE\_xxx Function Parameters**

| Parameters  | Description                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_type | The type of object to be compared. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW. |
| name1       | The name of the first object in the comparison.                                                                                                                                                                                                                                                          |
| name2       | The name of the second object in the comparison.                                                                                                                                                                                                                                                         |
| schema1     | The schema of the first object in the comparison. The default is the current user.                                                                                                                                                                                                                       |
| schema2     | The schema of the second object in the comparison. The default is the value of schema1.                                                                                                                                                                                                                  |

**Table 111-1 (Cont.) COMPARE\_xxx Function Parameters**

| Parameters                 | Description                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>network_link1</code> | The name of a database link to the database on which the first object resides. If NULL (the default), then the object is assumed to be in the database on which the caller is running. |
| <code>network_link2</code> | The name of a database link to the database on which the second object resides. The default is the value of <code>network_link1</code> .                                               |

### Return Values

`DBMS_METADATA_DIFF.COMPARE_xxx` returns the differences between two objects.

### Exceptions

- `INVALID_ARGVAL`  
A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `OBJECT_NOT_FOUND`  
The specified object was not found in the database.

### Usage Notes

These functions encapsulate calls to both `DBMS_METADATA` and `DBMS_METADATA_DIFF` functions and procedures to fetch the metadata for each of the two objects and compare them.

Which function you use depends on the comparison format you want:

- `COMPARE_SXML` returns an SXML difference document.
- `COMPARE_ALTER` returns a set of ALTER statements for making the first object like the second object.
- `COMPARE_ALTER_XML` returns an ALTER\_XML document.

## 111.4 Summary of DBMS\_METADATA\_DIFF Subprograms

The `DBMS_METADATA_DIFF` subprograms provide comparison functionality for different object types.

These subprograms are used to:

- Specify the type of objects to be compared
- Specify the SXML documents to be compared
- Show the differences between the compared documents
- Clean up after the comparison

Table 111-2 provides a summary of `DBMS_METADATA_DIFF` subprograms.

**Table 111-2 DBMS\_METADATA\_DIFF Package Subprograms**

| Subprogram                                          | Description                                                                                             |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">OPENC Function</a>                      | Specifies the type of objects to be compared                                                            |
| <a href="#">ADD_DOCUMENT Procedure</a>              | Specifies an SXML document to be compared                                                               |
| <a href="#">FETCH_CLOB Functions and Procedures</a> | Returns a CLOB showing the differences between the two documents specified by <code>ADD_DOCUMENT</code> |
| <a href="#">CLOSE Procedure</a>                     | Invalidates the handle returned by <code>OPENC</code> and cleans up associated state                    |

## 111.4.1 OPENC Function

This function specifies the type of objects to be compared. The return value is an opaque context handle.

### Syntax

```
DBMS_METADATA_DIFF.OPENC (  
  object_type IN VARCHAR2)  
RETURN NUMBER;
```

### Parameters

**Table 111-3 OPENC Function Parameters**

| Parameters               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object_type</code> | The type of object to be compared. Valid type names are <code>CLUSTER</code> , <code>CONTEXT</code> , <code>DB_LINK</code> , <code>FGA_POLICY</code> , <code>INDEX</code> , <code>MATERIALIZED_VIEW</code> , <code>MATERIALIZED_VIEW_LOG</code> , <code>QUEUE</code> , <code>QUEUE_TABLE</code> , <code>RLS_CONTEXT</code> , <code>RLS_GROUP</code> , <code>RLS_POLICY</code> , <code>ROLE</code> , <code>SEQUENCE</code> , <code>SYNONYM</code> , <code>TABLE</code> , <code>TABLESPACE</code> , <code>TRIGGER</code> , <code>TYPE</code> , <code>TYPE_SPEC</code> , <code>TYPE_BODY</code> , <code>USER</code> , and <code>VIEW</code> . |

### Return Values

The opaque handle that is returned is used as input to `ADD_DOCUMENT`, `FETCH_XXX` and `CLOSE`.

### Exceptions

- `INVALID_ARGVAL`  
A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

## 111.4.2 ADD\_DOCUMENT Procedure

This procedure specifies an SXML document that is to be compared.

### Syntax

```
DBMS_METADATA_DIFF.ADD_DOCUMENT(  
  handle IN NUMBER, document IN sys.XMLType);
```

```
DBMS_METADATA_DIFF.ADD_DOCUMENT(  
handle IN NUMBER, document IN CLOB);
```

### Parameters

**Table 111-4** ADD\_DOCUMENT Procedure Parameters

| Parameter | Description                                                                     |
|-----------|---------------------------------------------------------------------------------|
| handle    | The handle returned from OPENC                                                  |
| document  | A document to be compared. The document must be of the type specified in OPENC. |

### Usage Notes

Because the comparison interface allows you to compare exactly two SXML documents, a program must call `ADD_DOCUMENT` exactly twice for each `OPENC` handle. In the comparison result, the document specified by the first call is document 1, and the document specified by the second call is document 2.

### Exceptions

- INVALID\_ARGVAL

A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

## 111.4.3 FETCH\_CLOB Functions and Procedures

The `FETCH_CLOB` functions and procedures return a CLOB showing the differences between the two documents specified by `ADD_DOCUMENT`.

### Syntax

```
DBMS_METADATA_DIFF.FETCH_CLOB(  
handle IN NUMBER)  
RETURN CLOB;
```

```
DBMS_METADATA_DIFF.FETCH_CLOB(  
  
handle IN NUMBER,  
doc IN OUT NOCOPY CLOB);
```

```
DBMS_METADATA_DIFF.FETCH_CLOB(  
handle IN NUMBER,  
doc IN OUT NOCOPY CLOB  
diffs OUT BOOLEAN);
```

### Parameters

**Table 111-5** FETCH\_CLOB Subprogram Parameters

| Parameter | Description                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------|
| handle    | The handle returned from <code>OPENC</code> .                                                 |
| doc       | A CLOB containing the differences between documents 1 and 2.                                  |
| diffs     | <code>TRUE</code> if the documents are different or <code>FALSE</code> if they are identical. |

### Return Values

The differences between documents 1 and 2.

### Exceptions

- `INVALID_ARGVAL`

A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

## 111.4.4 CLOSE Procedure

This procedure invalidates the handle returned by `OPENC` and cleans up associated state.

### Syntax

```
DBMS_METADATA_DIFF.CLOSE(  
  handle IN NUMBER);
```

### Parameters

**Table 111-6** CLOSE Function Parameters

| Parameters | Description                                 |
|------------|---------------------------------------------|
| handle     | The handle returned from <code>OPENC</code> |

### Exceptions

- `INVALID_ARGVAL`

A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

# DBMS\_MGD\_ID\_UTL

The `DBMS_MGD_ID_UTL` package contains various utility functions and procedures.

These consist of the following utility subprograms:

- A logging utility that sets and gets Java and PL/SQL logging levels.
- A proxy utility consisting of two procedures used to set and unset the host and port of the proxy server.
- A metadata utility consisting of functions and procedures used for managing metadata.

## See Also:

*Oracle Database Development Guide* for more information.

This chapter describes each of these utility subprograms and contains the following topics:

- [Security Model](#)
- [Constants](#)
- [Exceptions](#)
- [Summary of DBMS\\_MGD\\_ID\\_UTL Subprograms](#)

The examples in this chapter assume that the user has run the following set of commands before running the contents of each script:

```
SQL> connect / as sysdba;
Connected.
SQL> create user mgduser identified by password;
SQL> grant connect, resource to mgduser;
SQL> connect mgduser
Enter password: mgduserpassword
Connected.
SQL> set serveroutput on;
```

## 112.1 DBMS\_MGD\_ID\_UTL Security Model

You must run the `catmgd.sql` script to load the `DBMS_MGD_ID_UTL` package and Identity Code Package schema objects in the `MGDSYS` schema.

`DBMS_MGD_ID_UTL` is a `MGDSYS`-owned package. Any `DBMS_MGD_ID_UTL` subprogram called from an anonymous PL/SQL block is run using the privileges of the current user.

A user must be granted `connect` and `resource` roles to use the `DBMS_MGD_ID_UTL` package and its subprograms.

`EXECUTE` privilege is granted to `PUBLIC` for these ADTs: `MGD_ID`, `MGD_ID_COMPONENT`, `MGD_ID_COMPONENT_VARRAY`, and for this package `DBMS_MGD_ID_UTL`.

SELECT or READ privilege is granted to PUBLIC for these read-only views: MGD\_ID\_CATEGORY and MGD\_ID\_SCHEME and for these metadata views: USER\_MGD\_ID\_CATEGORY and USER\_MGD\_ID\_SCHEME, and for table MGD\_ID\_XML\_VALIDATOR, and for sequence MGD\$SEQUENCE\_CATEGORY.

INSERT, UPDATE and DELETE privilege is granted to PUBLIC for these metadata views: USER\_MGD\_ID\_CATEGORY and USER\_MGD\_ID\_SCHEME.

Public synonyms, by the same name, are created for these ADTs: MGD\_ID, MGD\_ID\_COMPONENT, MGD\_ID\_COMPONENT\_VARRAY and for this package DBMS\_MGD\_ID\_UTL, as well as for these read-only views: MGD\_ID\_CATEGORY and MGD\_ID\_SCHEME and for these metadata views: USER\_MGD\_ID\_CATEGORY and USER\_MGD\_ID\_SCHEME, and for table MGD\_ID\_XML\_VALIDATOR.

## 112.2 DBMS\_MGD\_ID\_UTL Constants

The DBMS\_MGD\_ID\_UTL package defines several constants for specifying parameter values.

These constants are shown in the following tables.

**Table 112-1 DBMS\_MGD\_ID\_UTL Constants — Installed Category IDs and Names**

| Name                       | Value |
|----------------------------|-------|
| EPC_ENCODING_CATEGORY_ID   | 1     |
| EPC_ENCODING_CATEGORY_NAME | EPC   |

**Table 112-2 DBMS\_MGD\_ID\_UTL Constants — Logging Levels**

| Name                      | Value |
|---------------------------|-------|
| LOGGING_LEVEL_OF<br>F     | 0     |
| LOGGING_LEVEL_SE<br>VERE  | 1     |
| LOGGING_LEVEL_WA<br>RNING | 2     |
| LOGGING_LEVEL_IN<br>FO    | 3     |
| LOGGING_LEVEL_FI<br>NE    | 4     |
| LOGGING_LEVEL_FI<br>NER   | 5     |
| LOGGING_LEVEL_FI<br>NEST  | 6     |
| LOGGING_LEVEL_AL<br>L     | 7     |

## 112.3 DBMS\_MGD\_ID\_UTL Exceptions

The table in this topic lists the DBMS\_MGD\_ID\_UTL exceptions.

**Table 112-3 Exceptions Raised by DBMS\_MGD\_ID\_UTL Package**

| Name                        | Error Code | Description                                                                  |
|-----------------------------|------------|------------------------------------------------------------------------------|
| TDTJavaException            | -55200     | During the tag data translation, a Java exception was raised.                |
| TDTCategoryNotFound         | -55201     | The specified category was not found.                                        |
| TDTSchemeNotFound           | -55202     | During the tag data translation, the specified scheme was not found.         |
| TDTLevelNotFound            | -55203     | During the tag data translation, the specified level was not found.          |
| TDTOptionNotFound           | -55204     | During the tag data translation, the specified option was not found.         |
| TDTFieldValidationException | -55205     | During the tag data translation, the validation operation failed on a field. |
| TDTUndefinedField           | -55206     | During the tag data translation, an undefined field was detected.            |
| TDTRuleEvaluationFailed     | -55207     | During the tag data translation, the rule evaluation operation failed.       |
| TDTTooManyMatchingLevels    | -55208     | During the tag data translation, too many matching levels were found.        |

## 112.4 Summary of DBMS\_MGD\_ID\_UTL Subprograms

This table describes the utility subprograms in the DBMS\_MGD\_ID\_UTL package.

All the values and names passed to the procedures defined in the DBMS\_MGD\_ID\_UTL package are case insensitive unless otherwise mentioned. To preserve the case, enclose the values with double quotation marks.

**Table 112-4 DBMS\_MGD\_ID\_UTL Package Subprograms**

| Subprogram                                       | Description                                                                                        |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">ADD_SCHEME Procedure</a>             | Adds a tag data translation scheme to an existing category                                         |
| <a href="#">CREATE_CATEGORY Function</a>         | Creates a new category or a new version of a category                                              |
| <a href="#">EPC_TO_ORACLE_SCHEME Function</a>    | Converts the EPCglobal tag data translation (TDT) XML to Oracle tag data translation XML           |
| <a href="#">GET_CATEGORY_ID Function</a>         | Returns the category ID given the category name and the category version                           |
| <a href="#">GET_COMPONENTS Function</a>          | Returns all relevant separated component names separated by semicolon (;) for the specified scheme |
| <a href="#">GET_ENCODINGS Function</a>           | Returns a list of semicolon (;) separated encodings (formats) for the specified scheme             |
| <a href="#">GET_JAVA_LOGGING_LEVEL Function</a>  | Returns an integer representing the current Java trace logging level                               |
| <a href="#">GET_PLSQL_LOGGING_LEVEL Function</a> | Returns an integer representing the current PL/SQL trace logging level                             |
| <a href="#">GET_SCHEME_NAMES Function</a>        | Returns a list of semicolon (;) separated scheme names for the specified category                  |
| <a href="#">GET_TDT_XML Function</a>             | Returns the Oracle tag data translation XML for the specified scheme                               |

**Table 112-4 (Cont.) DBMS\_MGD\_ID\_UTL Package Subprograms**

| Subprogram                                        | Description                                                                                                          |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">GET_VALIDATOR Function</a>            | Returns the Oracle Database tag data translation schema                                                              |
| <a href="#">REFRESH_CATEGORY Function</a>         | Refreshes the metadata information on the Java stack for the specified category                                      |
| <a href="#">REMOVE_CATEGORY Procedure</a>         | Removes a category including all the related TDT XML if the value of <code>category_version</code> parameter is NULL |
| <a href="#">REMOVE_PROXY Procedure</a>            | Unsets the host and port of the proxy server                                                                         |
| <a href="#">REMOVE_SCHEME Procedure</a>           | Removes a tag data translation scheme from a category                                                                |
| <a href="#">SET_JAVA_LOGGING_LEVEL Procedure</a>  | Sets the Java logging level                                                                                          |
| <a href="#">SET_PLSQL_LOGGING_LEVEL Procedure</a> | Sets the PL/SQL tracing logging level                                                                                |
| <a href="#">SET_PROXY Procedure</a>               | Sets the host and port of the proxy server for Internet access                                                       |
| <a href="#">VALIDATE_SCHEME Function</a>          | Validates the input tag data translation XML against the Oracle tag data translation schema                          |

## 112.4.1 ADD\_SCHEME Procedure

This procedure adds a tag data translation scheme to an existing category.

### Syntax

```
DBMS_MGD_ID_UTL.ADD_SCHEME (  
    category_id IN  VARCHAR2,  
    tdt_xml      IN  CLOB);
```

### Parameters

**Table 112-5 ADD\_SCHEME Procedure Parameters**

| Parameter                | Description              |
|--------------------------|--------------------------|
| <code>category_id</code> | Category ID              |
| <code>tdt_xml</code>     | Tag data translation XML |

### Examples

This example performs the following actions:

1. Creates a category.
2. Adds a contractor scheme and an employee scheme to the `MGD_SAMPLE_CATEGORY` category.
3. Validates the `MGD_SAMPLE_CATEGORY` scheme.
4. Tests the tag translation of the contractor scheme and the employee scheme.
5. Removes the contractor scheme.
6. Tests the tag translation of the contractor scheme and this returns the expected exception for the removed contractor scheme.
7. Tests the tag translation of the employee scheme and this returns the expected values.

## 8. Removes the MGD\_SAMPLE\_CATEGORY category.

```

## 112.4.2 CREATE\_CATEGORY Function

This function creates a new category or a new version of a category.

### Syntax

```

DBMS_MGD_ID_UTL.CREATE_CATEGORY (
  category_name      IN  VARCHAR2,
  category_version   IN  VARCHAR2,
  agency             IN  VARCHAR2,

```

```
URI          IN VARCHAR2)
RETURN VARCHAR2;
```

**Parameters**

**Table 112-6 CREATE\_CATEGORY Function Parameters**

| Parameter        | Description                                                                        |
|------------------|------------------------------------------------------------------------------------|
| category_name    | Name of category                                                                   |
| category_version | Category version                                                                   |
| agency           | Organization that owns the category. For example, EPCglobal owns the category EPC. |
| URI              | URI that provides additional information about the category                        |

**Usage Notes**

The return value is the category ID.

**Examples**

See the [ADD\\_SCHEME Procedure](#) for an example of creating the MGD\_SAMPLE\_CATEGORY category.

### 112.4.3 EPC\_TO\_ORACLE\_SCHEME Function

This function converts the EPCglobal tag data translation (TDT) XML to Oracle Database tag data translation XML.

**Syntax**

```
DBMS_MGD_ID_UTL.EPC_TO_ORACLE_SCHEME (
    xml_scheme IN CLOB)
RETURN CLOB;
```

**Parameters**

**Table 112-7 EPC\_TO\_ORACLE\_SCHEME Function Parameters**

| Parameter  | Description                            |
|------------|----------------------------------------|
| xml_scheme | Name of EPC tag scheme to be converted |

**Usage Notes**

The return value is the contents of the CLOB containing the Oracle Datanase tag data translation XML.

**Examples**

The following example converts standard EPCglobal Tag Data Translation (TDT) files into Oracle Database TDT files:

```
--Contents of MGD_ID_DOC2.sql
-----
-- EPC_TO_ORACLE_SCHEME  --
-----
```

```

call DBMS_MGD_ID_UTL.set_proxy('www-proxy.example.com', '80');

BEGIN
  DBMS_JAVA.set_output(1000000);
  DBMS_OUTPUT.ENABLE(1000000);
  DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_SEVERE);
END;
/

## 112.4.4 GET\_CATEGORY\_ID Function

This function returns the category ID for a given category name and category version.

### Syntax

```
DBMS_MGD_ID_UTL.GET_CATEGORY_ID (
    category_name      IN  VARCHAR2,
    category_version   IN  VARCHAR2)
RETURN VARCHAR2;
```

### Parameters

**Table 112-8** GET\_CATEGORY\_ID Function Parameters

| Parameter        | Description      |
|------------------|------------------|
| category_name    | Name of category |
| category_version | Category version |

### Usage Notes

- If the value of `category_version` is NULL, then the ID of the latest version of the specified category is returned.
- The return value is the category ID for the specified category name.

### Examples

The following example returns a category ID given a category name and its version:

```
-- Contents of get_category1.sql file
SELECT DBMS_MGD_ID_UTL.get_category_id('EPC', NULL) FROM DUAL;

SQL> @get_category1.sql
.
.
.
```

```
DBMS_MGD_ID_UTL.GET_CATEGORY_ID('EPC',NULL)-----  
-----1  
.  
.  
.
```

### 112.4.5 GET\_COMPONENTS Function

This function returns all relevant separated component names separated by semicolon (;) for the specified scheme.

#### Syntax

```
DBMS_MGD_ID_UTL.GET_COMPONENTS (  
    category_id IN VARCHAR2,  
    scheme_name IN VARCHAR2)  
RETURN VARCHAR2;
```

#### Parameters

**Table 112-9 GET\_COMPONENTS Function Parameters**

| Parameter   | Description    |
|-------------|----------------|
| category_id | Category ID    |
| scheme_name | Name of scheme |

#### Usage Notes

The return value contains the component names separated by a semicolon (;) for the specified scheme.

#### Examples

The following example gets the components:

```
--Contents of get_components.sql  
DECLARE  
    id          mgd_id;  
    getcomps    VARCHAR2(1000);  
    getencodings VARCHAR2(1000);  
    getschemenames VARCHAR2(1000);  
BEGIN  
    DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);  
    DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));  
    getcomps := DBMS_MGD_ID_UTL.get_components(1,'SGTIN-64');  
    dbms_output.put_line('Component names are: ' || getcomps);  
    getencodings := DBMS_MGD_ID_UTL.get_encodings(1,'SGTIN-64');  
    dbms_output.put_line('Encodings are: ' || getencodings);  
    getschemenames := DBMS_MGD_ID_UTL.get_scheme_names(1);  
    dbms_output.put_line('Scheme names are: ' || getschemenames);  
END;  
/  
SHOW ERRORS;

Encodings are: ONS_HOSTNAME,LEGACY,TAG_ENCODING,PURE_IDENTITY,BINARY
Scheme names are:
GIAI-64,GIAI-96,GID-96,GRAI-64,GRAI-96,SGLN-64,SGLN-96,SGTIN-64,SGTIN-96,SSCC-64
,SSCC-96,USDOD-64,USDOD-96
PL/SQL procedure successfully completed.
.
.
.
```

## 112.4.6 GET\_ENCODING Function

This function returns a list of semicolon (;) separated encodings (formats) for the specified scheme.

### Syntax

```
DBMS_MGD_ID_UTL.GET_ENCODINGS (
    category_id IN VARCHAR2,
    scheme_name IN VARCHAR2)
RETURN VARCHAR2;
```

### Parameters

**Table 112-10 GET\_ENCODING Function Parameters**

| Parameter   | Description    |
|-------------|----------------|
| category_id | Category ID    |
| scheme_name | Name of scheme |

### Usage Notes

The return value contains the encodings separated by a semicolon (;) for the specified scheme.

### Examples

See the [GET\\_COMPONENTS Function](#) for an example.

## 112.4.7 GET\_JAVA\_LOGGING\_LEVEL Function

This function returns an integer representing the current trace logging level.

### Syntax

```
DBMS_MGD_ID_UTL.GET_JAVA_LOGGING_LEVEL
RETURN INTEGER;
```

### Usage Notes

The return value is the integer value denoting the current Java logging level.

### Examples

The following example gets the Java logging level.

```
--Contents of getjavalogginglevel.sql
DECLARE
```

```

        loglevel    NUMBER;
BEGIN
    DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
    loglevel := DBMS_MGD_ID_UTL.get_java_logging_level();
    dbms_output.put_line('Java logging level = ' || loglevel);
END;
/
SHOW ERRORS;

SQL> @getjavalogginglevel.sql
.
.
.
Java logging level = 0
PL/SQL procedure successfully completed.
.
.
.
```

## 112.4.8 GET\_PLSQL\_LOGGING\_LEVEL Function

This function returns an integer representing the current PL/SQL trace logging level.

### Syntax

```

DBMS_MGD_ID_UTL.GET_PLSQL_LOGGING_LEVEL
RETURN INTEGER;
```

```
PRAGMA restrict_references(get_plsql_logging_level, WNDS);
```

### Usage Notes

The return value is the integer value denoting the current PL/SQL logging level.

### Examples

The following example gets the PL/SQL logging level.

```

--Contents of getplsqllogginglevel.sql
DECLARE
    loglevel    NUMBER;
BEGIN
    DBMS_MGD_ID_UTL.set_plsql_logging_level(0);
    loglevel := DBMS_MGD_ID_UTL.get_plsql_logging_level();
    dbms_output.put_line('PL/SQL logging level = ' || loglevel);
END;
/
SHOW ERRORS;

SQL> @getplsqllogginglevel.sql
.
.
.
PL/SQL logging level = 0
PL/SQL procedure successfully completed.
.
.
.
```

## 112.4.9 GET\_SCHEME\_NAMES Function

This function returns a list of semicolon (;) separated scheme names for the specified category.

### Syntax

```
DBMS_MGD_ID_UTL.GET_SCHEME_NAMES (  
    category_id IN VARCHAR2)  
RETURN VARCHAR2;
```

### Parameters

**Table 112-11** GET\_SCHEME\_NAMES Function Parameters

| Parameter   | Description |
|-------------|-------------|
| category_id | Category ID |

### Usage Notes

The return value contains the scheme names for the specified category ID.

### Examples

See the [GET\\_COMPONENTS Function](#) for an example.

## 112.4.10 GET\_TDT\_XML Function

This function returns the Oracle Database tag data translation XML for the specified scheme.

### Syntax

```
DBMS_MGD_ID_UTL.GET_TDT_XML (  
    category_id IN VARCHAR2,  
    scheme_name IN VARCHAR2)  
RETURN CLOB;
```

### Parameters

**Table 112-12** GET\_TDT\_XML Function Parameters

| Parameter   | Description    |
|-------------|----------------|
| category_id | Category ID    |
| scheme_name | Name of scheme |

### Usage Notes

The return value contains the Oracle Database tag data translation XML for the specified scheme.

### Examples

The following example gets the Oracle Database TDT XML for the specified scheme:

```
--Contents of get_tdtxml.sql
DECLARE
    gettdtxml          CLOB;

BEGIN
    gettdtxml := DBMS_MGD_ID_UTL.get_tdt_xml(1,'SGTIN-64');
    dbms_output.put_line('Length of tdt XML is '||DBMS_LOB.GETLENGTH(gettdtxml));
    dbms_output.put_line(DBMS_LOB.SUBSTR(gettdtxml, DBMS_LOB.GETLENGTH(gettdtxml), 1));
END;
/

## 112.4.11 GET\_VALIDATOR Function

This function returns the Oracle Database tag data translation schema.

### Syntax

```
DBMS_MGD_ID_UTL.GET_VALIDATOR
RETURN CLOB;
```

### Usage Notes

The return value contains the Oracle Database tag data translation schema.

### Examples

This example returns the Oracle Database TDT schema.

```
--Contents of get_validator.sql
DECLARE
    getvalidator          CLOB;
BEGIN
    getvalidator := DBMS_MGD_ID_UTL.get_validator;
    dbms_output.put_line('Length of validated oracle scheme xml is '||DBMS_LOB.GETLENGTH(getvalidator));

## 112.4.12 REFRESH\_CATEGORY Function

This function refreshes the metadata information on the Java stack for the specified category.

This function must be called before using MGD\_ID functions.

### Syntax

```

DBMS_MGD_ID_UTL.REFRESH_CATEGORY (
    category_id IN VARCHAR2);

```

## Parameters

**Table 112-13 REFRESH\_CATEGORY Function Parameters**

| Parameter   | Description |
|-------------|-------------|
| category_id | Category ID |

## Examples

The following example refreshes the metadata information for the EPC category ID.

```
--Contents of tostring3.sql
call DBMS_MGD_ID_UTL.set_proxy('www-proxy.example.com', '80');
DECLARE
id          MGD_ID;
BEGIN
  DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
  DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));
  dbms_output.put_line('..Testing to_string');
  DBMS_OUTPUT.PUT_LINE('test to_string');
  id := mgd_id('EPC', NULL, 'urn:epc:id:gid:0037000.30241.1041970', 'scheme=GID-96');
  DBMS_OUTPUT.PUT_LINE('mgd_id object as a string');
  DBMS_OUTPUT.PUT_LINE(id.to_string);
END;
/
SHOW ERRORS;
call DBMS_MGD_ID_UTL.remove_proxy();

SQL> @tostring3.sql
..Testing to_string
test to_string
mgd_id object as a string
category_id =1;schemes = GID-96;objectclass = 30241;generalmanager =
0037000;scheme = GID-96;1 = 1;serial = 1041970

PL/SQL procedure successfully completed.
```

## 112.4.13 REMOVE\_CATEGORY Procedure

This procedure removes a category including all the related TDT XML.

This procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

### Syntax

Removes a category based on the specified category ID.

```
DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
  category_id IN VARCHAR2);
```

Removes a category based on the specified category name and category version.

```
DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
  category_name IN VARCHAR2,
  category_version IN VARCHAR2);
```

## Parameters

**Table 112-14 REMOVE\_CATEGORY Procedure Parameters**

| Parameter        | Description      |
|------------------|------------------|
| category_id      | Category ID      |
| category_name    | Name of category |
| category_version | Category version |

## Usage Notes

If the value of `category_version` is NULL, all versions for the specified category will be removed.

## Examples

See the [ADD\\_SCHEME Procedure](#) for an example of removing a category.

## 112.4.14 REMOVE\_PROXY Procedure

This procedure unsets the host and port of the proxy server.

## Syntax

```
DBMS_MGD_ID_UTL.REMOVE_PROXY;
```

## Examples

See the [REFRESH\\_CATEGORY Function](#) for an example.

## 112.4.15 REMOVE\_SCHEME Procedure

This procedure removes a tag data translation scheme from a category.

## Syntax

```
DBMS_MGD_ID_UTL.REMOVE_SCHEME (  
    category_id IN VARCHAR2,  
    scheme_name IN VARCHAR2);
```

## Parameters

**Table 112-15 REMOVE\_SCHEME Procedure Parameters**

| Parameter   | Description    |
|-------------|----------------|
| category_id | Category ID    |
| scheme_name | Name of scheme |

## Examples

See the [ADD\\_SCHEME Procedure](#) for an example of removing a scheme.

## 112.4.16 SET\_JAVA\_LOGGING\_LEVEL Procedure

This procedure sets the Java trace logging level.

### Syntax

```
DBMS_MGD_ID_UTL.SET_JAVA_LOGGING_LEVEL (  
    logginglevel IN INTEGER);
```

### Parameters

**Table 112-16 SET\_JAVA\_LOGGING\_LEVEL Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| logginglevel | Logging level. The Java logging level can be one of the following values in descending order: <ul style="list-style-type: none"><li>LOGGING_LEVEL_OFF CONSTANT INTEGER := 0</li><li>LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1</li><li>LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2</li><li>LOGGING_LEVEL_INFO CONSTANT INTEGER := 3</li><li>LOGGING_LEVEL_FINE CONSTANT INTEGER := 4</li><li>LOGGING_LEVEL_FINER CONSTANT INTEGER := 5</li><li>LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6</li><li>LOGGING_LEVEL_ALL CONSTANT INTEGER := 7</li></ul> |

### Examples

See the [GET\\_JAVA\\_LOGGING\\_LEVEL Function](#) for an example.

## 112.4.17 SET\_PLSQL\_LOGGING\_LEVEL Procedure

This procedure sets the PL/SQL trace logging level.

### Syntax

```
DBMS_MGD_ID_UTL.SET_PLSQL_LOGGING_LEVEL (  
    level IN INTEGER);  
  
PRAGMA restrict_references(set_plsql_logging_level, WNDS);
```

## Parameters

**Table 112-17 SET\_PLSQL\_LOGGING\_LEVEL Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| level     | Logging level. The PL/SQL logging level can be one of the following values in descending order: <ul style="list-style-type: none"><li>LOGGING_LEVEL_OFF CONSTANT INTEGER := 0</li><li>LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1</li><li>LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2</li><li>LOGGING_LEVEL_INFO CONSTANT INTEGER := 3</li><li>LOGGING_LEVEL_FINE CONSTANT INTEGER := 4</li><li>LOGGING_LEVEL_FINER CONSTANT INTEGER := 5</li><li>LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6</li><li>LOGGING_LEVEL_ALL CONSTANT INTEGER := 7</li></ul> |

## Examples

See the [GET\\_PLSQL\\_LOGGING\\_LEVEL Function](#) for an example.

## 112.4.18 SET\_PROXY Procedure

This procedure sets the host and port of the proxy server for Internet access.

This procedure must be called if the database server accesses the Internet using a proxy server. Internet access is necessary because some rules need to look up the Object Naming Service (ONS) table to get the company prefix index.

You do not need to call this procedure if you are only using schemes that do not contain any rules requiring Internet access.

## Syntax

```
DBMS_MGD_ID_UTL.SET_PROXY (  
    proxt_host    IN  VARCHAR2,  
    proxy_port    IN  VARCHAR2);
```

## Parameters

**Table 112-18 SET\_PROXY Procedure Parameters**

| Parameter  | Description      |
|------------|------------------|
| proxy_host | Name of host     |
| proxy_port | Host port number |

## Examples

See the [REFRESH\\_CATEGORY Function](#) for an example.

# 112.4.19 VALIDATE\_SCHEME Function

This function validates the input tag data translation XML against the Oracle Database tag data translation schema.

## Syntax

```
DBMS_MGD_ID_UTL.VALIDATE_SCHEME (  
    xml_scheme IN CLOB)  
RETURN VARCHAR2;
```

## Parameters

**Table 112-19** VALIDATE\_SCHEME Function Parameters

| Parameter  | Description             |
|------------|-------------------------|
| xml_scheme | Scheme to be validated. |

## Usage Notes

The return value contains the components names for the specified scheme.

## Examples

See the [ADD\\_SCHEME Procedure](#) or the [EPC\\_TO\\_ORACLE\\_SCHEME Function](#) for an example.

# DBMS\_MGWADM

DBMS\_MGWADM defines the Messaging Gateway administrative interface. The package and object types are owned by SYS.

**Note:**

You must run the `catmgw.sql` script to load the Messaging Gateway packages and types into the database.

**See Also:**

*Oracle Database Advanced Queuing User's Guide* contains information on loading database objects and using DBMS\_MGWADM

This chapter contains the following topics:

- [Security Model](#)
- [Deprecated Subprograms](#)
- [Constants](#)
- [Data Structures](#)
- [Summary of DBMS\\_MGWADM Subprograms](#)

## 113.1 DBMS\_MGWADM Security Model

A user with administrative privilege can run all procedures in DBMS\_MGWADM.

## 113.2 DBMS\_MGWADM Deprecated Subprograms

Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with Oracle Database 11g Release 1 having been superseded by improved technology:

- [ADD\\_SUBSCRIBER Procedure](#) - use instead [CREATE\\_JOB Procedure](#)
- [ALTER\\_PROPAGATION\\_SCHEDULE Procedure](#) - use instead [ALTER\\_JOB Procedure](#)
- [ALTER\\_SUBSCRIBER Procedure](#) - use instead [ALTER\\_JOB Procedure](#)
- [DB\\_CONNECT\\_INFO Procedure](#) - use instead [ALTER\\_AGENT Procedures](#)
- [DISABLE\\_PROPAGATION\\_SCHEDULE Procedure](#) - use instead [DISABLE\\_JOB Procedure](#)

- [ENABLE\\_PROPAGATION\\_SCHEDULE Procedure](#) - use instead [ENABLE\\_JOB Procedure](#)
- [REMOVE\\_SUBSCRIBER Procedure](#) - use instead [REMOVE\\_JOB Procedure](#)
- [RESET\\_SUBSCRIBER Procedure](#) - use instead [RESET\\_JOB Procedure](#)
- [SCHEDULE\\_PROPAGATION Procedure](#) - use instead [CREATE\\_JOB Procedure](#)
- [UNSCHEDULE\\_PROPAGATION Procedure](#) - use instead [REMOVE\\_JOB Procedure](#)

## 113.3 DBMS\_MGWADM Constants

The DBMS\_MGWADM package defines various constants for specifying parameter values.

- [Table 113-1](#)
- [Table 113-2](#)
- [Table 113-3](#)
- [Table 113-4](#)
- [Table 113-5](#)
- [Table 113-6](#)
- [Table 113-7](#)
- [Table 113-8](#)
- [Table 113-9](#)
- [Table 113-10](#)
- [Table 113-11](#)

**Table 113-1 DBMS\_MGWADM Constants—Cleanup Actions**

| Name                      | Type                    | Description                                                                                                                |
|---------------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------|
| CLEAN_STARTUP_STATE       | CONSTANT BINARY_INTEGER | Sets the Messaging Gateway agent to a known state so that it can be started                                                |
| CLEAN_LOG_QUEUES          | CONSTANT BINARY_INTEGER | Messaging Gateway agent will clean log queues for all configured messaging system links                                    |
| RESET_SUB_MISSING_LOG_REC | CONSTANT BINARY_INTEGER | Messaging Gateway agent recovers a Messaging Gateway subscriber that has failed due to a missing log record                |
| RESET_SUB_MISSING_MESSAGE | CONSTANT BINARY_INTEGER | Messaging Gateway agent recovers a Messaging Gateway subscriber that has failed due to a missing persistent source message |

**Table 113-2 DBMS\_MGWADM Constants—Force Values**

| Name     | Type                    | Description                           |
|----------|-------------------------|---------------------------------------|
| FORCE    | CONSTANT BINARY_INTEGER | Represents a forced action            |
| NO_FORCE | CONSTANT BINARY_INTEGER | Represents a normal, nonforced action |

**Table 113-3 DBMS\_MGWADM Constants—Logging Levels**

| Name                | Type                    | Description                                                              |
|---------------------|-------------------------|--------------------------------------------------------------------------|
| BASIC_LOGGING       | CONSTANT BINARY_INTEGER | The standard (the least) information written to the log file             |
| TRACE_DEBUG_LOGGING | CONSTANT BINARY_INTEGER | The greatest information written to the log file                         |
| TRACE_HIGH_LOGGING  | CONSTANT BINARY_INTEGER | The third level of detail of logging information written to the log file |
| TRACE_LITE_LOGGING  | CONSTANT BINARY_INTEGER | The second level detail of logging information written to the log file   |

**Table 113-4 DBMS\_MGWADM Constants—Named Property Constants**

| Name               | Type              | Description                                                                                      |
|--------------------|-------------------|--------------------------------------------------------------------------------------------------|
| MGWPROP_PREFIX     | CONSTANT VARCHAR2 | A constant (MGWPROP\$_) for the reserved property name prefix                                    |
| MGWPROP_REMOVE     | CONSTANT VARCHAR2 | A constant (MGWPROP\$_REMOVE) for the reserved property name used to remove an existing property |
| MGWPROP_REMOVE_ALL | CONSTANT VARCHAR2 | A constant (MGWPROP\$_REMOVE_ALL) for the reserved property name used to remove all properties   |

**Table 113-5 DBMS\_MGWADM Constants—Other Constants**

| Name                 | Type                    | Description                                                                                                                                                                        |
|----------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JMS_CONNECTION       | CONSTANT BINARY_INTEGER | Used to indicate that JMS connections will be used to access JMS destinations in a domain-independent manner that supports a unified messaging model                               |
| JMS_QUEUE_CONNECTION | CONSTANT BINARY_INTEGER | Used to indicate that JMS queue connections will be used to access JMS destinations                                                                                                |
| JMS_TOPIC_CONNECTION | CONSTANT BINARY_INTEGER | Used to indicate that JMS topic connections will be used to access JMS destinations                                                                                                |
| NO_CHANGE            | CONSTANT VARCHAR2       | Indicates that an existing value should be preserved (not changed). This is used for certain APIs where the desire is to change one or more parameters but leave others unchanged. |
| DEFAULT_AGENT        | CONSTANT VARCHAR2       | Name of the Messaging Gateway default agent                                                                                                                                        |

**Table 113-6 DBMS\_MGWADM Constants—Propagation Types**

| Name                 | Type                    | Description                                                                                                                                                                                                                                         |
|----------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INBOUND_PROPAGATION  | CONSTANT BINARY_INTEGER | Represents the propagation type for non-Oracle to Oracle Database Advanced Queuing propagation. The propagation source is a queue in a foreign (non-Oracle) messaging system and the destination is a local Oracle Database Advanced Queuing queue. |
| OUTBOUND_PROPAGATION | CONSTANT BINARY_INTEGER | Represents the propagation type for Oracle Database Advanced Queuing to non-Oracle propagation. The propagation source is a local Oracle Database Advanced Queuing queue and the destination is a queue in a foreign (non-Oracle) messaging system. |

**Table 113-7 DBMS\_MGWADM Constants—Queue Domain Types**

| Name         | Type                    | Description                                                                                     |
|--------------|-------------------------|-------------------------------------------------------------------------------------------------|
| DOMAIN_QUEUE | CONSTANT BINARY_INTEGER | Represents a queue destination. A JMS queue (point-to-point model) is classified as a queue.    |
| DOMAIN_TOPIC | CONSTANT BINARY_INTEGER | Represents a topic destination. A JMS topic (publish-subscribe model) is classified as a topic. |

**Table 113-8 DBMS\_MGWADM Constants—Shutdown Modes**

| Name               | Type                    | Description                            |
|--------------------|-------------------------|----------------------------------------|
| SHUTDOWN_IMMEDIATE | CONSTANT BINARY_INTEGER | Represents the immediate shutdown mode |
| SHUTDOWN_NORMAL    | CONSTANT BINARY_INTEGER | Represents the normal shutdown mode    |

**Table 113-9 DBMS\_MGWADM Constants—WebSphere MQ Interface Types**

| Name                         | Type                    | Description                                                              |
|------------------------------|-------------------------|--------------------------------------------------------------------------|
| MQSERIES_BASE_JAVA_INTERFACE | CONSTANT BINARY_INTEGER | Represents the Base Java interface for the WebSphere MQ messaging system |

**Table 113-10 DBMS\_MGWADM Constants—target\_type Argument of SET\_OPTION and REMOVE\_OPTION Procedures**

| Name            | Type                 | Description                                                 |
|-----------------|----------------------|-------------------------------------------------------------|
| AGENT_JAVA_PROP | CONSTANT PLS_INTEGER | Used for an agent option used to set a Java System property |
| MSGLINK_OPTION  | CONSTANT PLS_INTEGER | Used for a messaging system link option                     |
| JOB_OPTION      | CONSTANT PLS_INTEGER | Used for a propagation job option                           |

**Table 113-11 DBMS\_MGWADM Constants—conntype Argument of CREATE\_AGENT and ALTER\_AGENT Procedures**

| Name      | Type              | Description                          |
|-----------|-------------------|--------------------------------------|
| JDBC_OCI  | CONSTANT VARCHAR2 | Used to specify the JDBC OCI driver  |
| JDBC_THIN | CONSTANT VARCHAR2 | Used to specify the JDBC Thin driver |

## 113.4 DBMS\_MGWADM Data Structures

The DBMS\_MGWADM package defines several OBJECT types.

### DBMS\_MGWADM Object Types

- [SYS.MGW\\_MQSERIES\\_PROPERTIES Object Type](#)
- [SYS.MGW\\_PROPERTIES Object Type](#)
- [SYS.MGW\\_PROPERTY Object Type](#)
- [SYS.MGW\\_TIBRV\\_PROPERTIES Object Type](#)

### 113.4.1 DBMS\_MGWADM SYS.MGW\_MQSERIES\_PROPERTIES Object Type

This type specifies basic properties for a WebSphere MQ messaging system link.

#### Syntax

```
TYPE SYS.MGW_MQSERIES_PROPERTIES IS OBJECT (  
    queue_manager    VARCHAR2 (64),  
    hostname         VARCHAR2 (64),  
    port             INTEGER,  
    channel          VARCHAR2 (64),  
    interface_type   INTEGER,  
    username         VARCHAR2 (64),  
    password         VARCHAR2 (64),  
    inbound_log_queue VARCHAR2 (64),  
    outbound_log_queue VARCHAR2 (64),  
  
    -- Methods  
    STATIC FUNCTION construct  
    RETURN SYS.MGW_MQSERIES_PROPERTIES,  
  
    STATIC FUNCTION alter_construct  
    RETURN SYS.MGW_MQSERIES_PROPERTIES );
```

#### Attributes

**Table 113-12 SYS.MGW\_MQSERIES\_PROPERTIES Attributes**

| Attribute     | Description                                |
|---------------|--------------------------------------------|
| queue_manager | The name of the WebSphere MQ queue manager |

**Table 113-12 (Cont.) SYS.MGW\_MQSERIES\_PROPERTIES Attributes**

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hostname          | The host on which the WebSphere MQ messaging system resides. If hostname is NULL, then a WebSphere MQ bindings connection is used. If not NULL, then a client connection is used and requires that a port and channel be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| port              | The port number. This is used only for client connections; that is, when hostname is not NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| channel           | The channel used when establishing a connection to the queue manager. This is used only for client connections; that is, when hostname is not NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| interface_type    | <p>The type of messaging interface to use. Values:</p> <ul style="list-style-type: none"> <li>• DBMS_MGWADM.MQSERIES_BASE_JAVA_INTERFACE if the WebSphere MQ Base Java interface should be used.</li> <li>• DBMS_MGWADM.JMS_CONNECTION if the link is to be used to access JMS destinations in a unified, domain-independent manner.</li> <li>• DBMS_MGWADM.JMS_QUEUE_CONNECTION if the link is to be used for accessing JMS queues</li> <li>• DBMS_MGWADM.JMS_TOPIC_CONNECTION if the link is to be used for accessing JMS topics.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                |
| username          | The username used for authentication to the WebSphere MQ messaging system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| password          | The password used for authentication to the WebSphere MQ messaging system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| inbound_log_queue | <p>The name of the WebSphere MQ queue used for propagation recovery purposes when this messaging link is used for inbound propagation; that is, when queues associated with this link serve as a propagation source:</p> <ul style="list-style-type: none"> <li>• For MQSERIES_BASE_JAVA_INTERFACE, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools.</li> <li>• For the JMS_CONNECTION interface and the JMS_QUEUE_CONNECTION interface, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools.</li> <li>• For JMS_TOPIC_CONNECTION interface, this specifies the name of a WebSphere MQ JMS topic. The physical WebSphere MQ queue used by subscribers of that topic must be created using WebSphere MQ administration tools. By default, the physical queue used is SYSTEM.JMS.D.SUBSCRIBER.QUEUE.</li> </ul> |

**Table 113-12 (Cont.) SYS.MGW\_MQSERIES\_PROPERTIES Attributes**

| Attribute          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

#### Methods

**Table 113-13 SYS.MGW\_MQSERIES\_PROPERTIES Methods**

| Method          | Description                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| construct       | Constructs a new <code>SYS.MGW_MQSERIES_PROPERTIES</code> instance. All attributes are assigned a value of <code>NULL</code> .                                                                                                                                                                                              |
| alter_construct | Constructs a new <code>SYS.MGW_MQSERIES_PROPERTIES</code> instance for altering the properties of an existing messaging link. All attributes having a <code>VARCHAR2</code> datatype are assigned a value of <code>DBMS_MGWADM.NO_CHANGE</code> . Attributes of other datatypes are assigned a value of <code>NULL</code> . |

## 113.4.2 DBMS\_MGWADM SYS.MGW\_PROPERTIES Object Type

This type specifies an array of properties.

#### Syntax

```
TYPE SYS.MGW_PROPERTIES AS VARRAY (2000) OF SYS.MGW_PROPERTY;
```

#### Attributes

**Table 113-14 SYS.MGW\_PROPERTIES Attributes**

| Attribute | Description    |
|-----------|----------------|
| name      | Property name  |
| value     | Property value |

#### Usage Notes

Unless noted otherwise, Messaging Gateway uses named properties as follows:

- Names with the `MGWPROP$_` prefix are reserved. They are used for special purposes and are invalid when used as a normal property name.
- A property name can exist only once in a property list; that is, a list can contain only one value for a given name. The name is case-insensitive.
- In general, a property list is order-independent, and the property names may appear in any order. An alter property list is an exception.
- You can use a new property list to alter an existing property list. Each new property modifies the original list in one of the following ways: adds a new property, modifies a property, removes a property, or removes all properties.

The alter list is processed in order, from the first element to the last element. Thus the order in which the elements appear in the alter list is meaningful, especially when the alter list is used to remove properties from an existing list.

The property name and value are used to determine how that element affects the original list. The following rules apply:

- Add or modify property

```
MGW_PROPERTY.NAME = property_name
MGW_PROPERTY.VALUE = property_value
```

If a property of the given name already exists, then the current value is replaced with the new value; otherwise the new property is added to the end of the list.

- Remove property

```
MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE'
MGW_PROPERTY.VALUE = name_of_property_to_remove
```

No action is taken if the property name does not exist in the original list.

- Remove all properties

```
MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE_ALL'
MGW_PROPERTY.VALUE = not used
```

## 113.4.3 DBMS\_MGWADM SYS.MGW\_PROPERTY Object Type

This type specifies a named property which is used to specify optional properties for messaging links, foreign queues, and subscribers.

### Syntax

```
TYPE SYS.MGW_PROPERTY IS OBJECT(
    name  VARCHAR2(500),
    value VARCHAR2(4000),

-- Methods
STATIC FUNCTION construct    --- (1)
RETURN SYS.MGW_PROPERTY,
```

```
STATIC FUNCTION construct( --- (2)
    p_name   IN VARCHAR2,
    p_value  IN VARCHAR2)
RETURN SYS.MGW_PROPERTY );
```

### Attributes

**Table 113-15** SYS.MGW\_PROPERTY Attributes

| Attribute | Description    |
|-----------|----------------|
| name      | Property name  |
| value     | Property value |

### Methods

**Table 113-16** SYS.MGW\_PROPERTY Methods

| Method            | Description                                                                         |
|-------------------|-------------------------------------------------------------------------------------|
| construct --- (1) | Constructs a new MGW_PROPERTY instance. All attributes are assigned a value of NULL |
| construct --- (2) | Constructs a new MGW_PROPERTY instance initialized using the given parameters       |

#### See Also:

"The DBMS\_MGWADM package defines constants to represent the reserved property names on [Table 113-4](#)

## 113.4.4 SYS.MGW\_TIBRV\_PROPERTIES Object Type

A type that specifies basic properties for a TIB/Rendezvous messaging system link. The Messaging Gateway agent creates a TIB/Rendezvous transport of type `TibrvRvdTransport` for each Messaging Gateway link.

### Syntax

```
TYPE SYS.MGW_TIBRV_PROPERTIES IS OBJECT(
    service   VARCHAR2(128),
    daemon    VARCHAR2(128),
    network   VARCHAR2(256),
    cm_name   VARCHAR2(256),
    cm_ledger VARCHAR2(256),

    -- Methods
    STATIC FUNCTION construct
    RETURN SYS.MGW_TIBRV_PROPERTIES,

    STATIC FUNCTION alter_construct
    RETURN SYS.MGW_TIBRV_PROPERTIES );
```

## Attributes

**Table 113-17 SYS.MGW\_TIBRV\_PROPERTIES Attributes**

| Attribute | Description                                         |
|-----------|-----------------------------------------------------|
| service   | The service parameter for the rvd transport         |
| daemon    | The daemon parameter for the rvd transport          |
| network   | The network parameter for the rvd transport         |
| cm_name   | The CM correspondent name. Reserved for future use. |
| cm_ledger | The CM ledger file name. Reserved for future use.   |

## Methods

**Table 113-18 SYS.MGW\_TIBRV\_PROPERTIES Methods**

| Method          | Description                                                                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| construct       | Constructs a new SYS.MGW_TIBRV_PROPERTIES instance. All attributes will be assigned a value of NULL.                                                                                                                                                                                                |
| alter_construct | Constructs a new SYS.MGW_TIBRV_PROPERTIES instance. This function is useful for altering the properties of an existing messaging link. All attributes having a VARCHAR2 datatype will be assigned a value of DBMS_MGWADM.NO_CHANGE. Attributes of other datatypes will be assigned a value of NULL. |

# 113.5 Summary of DBMS\_MGWADM Subprograms

This table lists the DBMS\_MGWADM subprograms and briefly describes them.

**Table 113-19 DBMS\_MGWADM Package Subprograms**

| Subprogram                                                        | Description                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_SUBSCRIBER Procedure</a>                          | Adds a subscriber used to consume messages from a source queue for propagation to a destination                     |
| <a href="#">ALTER_AGENT Procedures</a>                            | Alters Messaging Gateway agent parameters                                                                           |
| <a href="#">ALTER_JOB Procedure</a>                               | Alters the properties of a propagation job                                                                          |
| <a href="#">ALTER_MSGSYSTEM_LINK Procedure for TIB/Rendezvous</a> | Alters the properties of a TIB/Rendezvous messaging system link                                                     |
| <a href="#">ALTER_MSGSYSTEM_LINK Procedure for WebSphere MQ</a>   | Alters the properties of a WebSphere MQ messaging system link                                                       |
| <a href="#">ALTER_PROPAGATION_SCHEDULE Procedure</a>              | Alters a propagation schedule                                                                                       |
| <a href="#">ALTER_SUBSCRIBER Procedure</a>                        | Alters the parameters of a subscriber used to consume messages from a source queue for propagation to a destination |
| <a href="#">CLEANUP_GATEWAY Procedures</a>                        | Cleans up Messaging Gateway                                                                                         |
| <a href="#">CREATE_AGENT Procedure</a>                            | Creates a Messaging Gateway agent that will be used to process propagation jobs                                     |

**Table 113-19 (Cont.) DBMS\_MGWADM Package Subprograms**

| Subprogram                                                          | Description                                                                                              |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">CREATE_JOB Procedure</a>                                | Creates a job used to propagate message from a source to a destination                                   |
| <a href="#">CREATE_MSGSYSTEM_LINK Procedures for TIB/Rendezvous</a> | Creates a messaging system link to a TIB/Rendezvous messaging system                                     |
| <a href="#">CREATE_MSGSYSTEM_LINK Procedures for WebSphere MQ</a>   | Creates a messaging system link to a WebSphere MQ messaging system                                       |
| <a href="#">DB_CONNECT_INFO Procedure</a>                           | Configures connection information used by the Messaging Gateway agent for connections to Oracle Database |
| <a href="#">DISABLE_JOB Procedure</a>                               | Disables a propagation job                                                                               |
| <a href="#">DISABLE_PROPAGATION_SCHEDULE Procedure</a>              | Disables a propagation schedule                                                                          |
| <a href="#">ENABLE_JOB Procedure</a>                                | Enables a propagation job                                                                                |
| <a href="#">ENABLE_PROPAGATION_SCHEDULE Procedure</a>               | Enables a propagation schedule                                                                           |
| <a href="#">REGISTER_FOREIGN_QUEUE Procedure</a>                    | Registers a non-Oracle queue entity in Messaging Gateway                                                 |
| <a href="#">REMOVE_AGENT Procedure</a>                              | Removes a Messaging Gateway agent                                                                        |
| <a href="#">REMOVE_JOB Procedure</a>                                | Removes a propagation job                                                                                |
| <a href="#">REMOVE_MSGSYSTEM_LINK Procedure</a>                     | Removes a messaging system link for a non-Oracle messaging system                                        |
| <a href="#">REMOVE_OPTION Procedure</a>                             | Removes a Messaging Gateway configuration option                                                         |
| <a href="#">REMOVE_SUBSCRIBER Procedure</a>                         | Removes a subscriber used to consume messages from a source queue for propagation to a destination       |
| <a href="#">RESET_JOB Procedure</a>                                 | Resets the propagation error state for a propagation job                                                 |
| <a href="#">RESET_SUBSCRIBER Procedure</a>                          | Resets the propagation error state for a subscriber                                                      |
| <a href="#">SCHEDULE_PROPAGATION Procedure</a>                      | Schedules message propagation from a source to a destination                                             |
| <a href="#">SET_LOG_LEVEL Procedures</a>                            | Dynamically alters the Messaging Gateway agent logging level                                             |
| <a href="#">SET_OPTION Procedure</a>                                | Sets a Messaging Gateway configuration option                                                            |
| <a href="#">SHUTDOWN Procedures</a>                                 | Shuts down the Messaging Gateway agent                                                                   |
| <a href="#">STARTUP Procedures</a>                                  | Starts the Messaging Gateway agent                                                                       |
| <a href="#">UNREGISTER_FOREIGN_QUEUE Procedure</a>                  | Removes a non-Oracle queue entity in Messaging Gateway                                                   |
| <a href="#">UNSCHEDULE_PROPAGATION Procedure</a>                    | Removes a propagation schedule                                                                           |

## 113.5.1 ADD\_SUBSCRIBER Procedure

This procedure adds a subscriber used to consume messages from a source queue for propagation to a destination.

### Note:

This subprogram has been deprecated as a result of improved technology (see [CREATE\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.ADD_SUBSCRIBER(  
  subscriber_id      IN VARCHAR2,  
  propagation_type   IN BINARY_INTEGER,  
  queue_name         IN VARCHAR2,  
  destination        IN VARCHAR2,  
  rule               IN VARCHAR2 DEFAULT NULL,  
  transformation      IN VARCHAR2 DEFAULT NULL,  
  exception_queue     IN VARCHAR2 DEFAULT NULL  
  options            IN SYS.MGW_PROPERTIES DEFAULT NULL);
```

### Parameters

**Table 113-20    ADD\_SUBSCRIBER Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subscriber_id    | Specifies a user-defined name that identifies this subscriber                                                                                                                                                                                                                                                                                      |
| propagation_type | Specifies the type of message propagation.<br>DBMS_MGWADM.OUTBOUND_PROPAGATION is for Oracle Database Advanced Queuing to non-Oracle propagation.<br>DBMS_MGWADM.INBOUND_PROPAGATION is for non-Oracle to Oracle Database Advanced Queuing propagation                                                                                             |
| queue_name       | Specifies the source queue to which this subscriber is being added. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                                                                                            |
| destination      | Specifies the destination queue to which messages consumed by this subscriber are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                                                                  |
| rule             | Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. This is NULL if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                   |
| transformation   | Specifies the transformation needed to convert between the Oracle Database Advanced Queuing payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for propagation_type.<br><br>If NULL, then the Oracle Database Advanced Queuing payload type must be supported by Messaging Gateway. |

Table 113-20 (Cont.) ADD\_SUBSCRIBER Procedure Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exception_queue | Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. If <code>NULL</code> , then an exception queue is not used and propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code> .<br>The source queue and exception queue cannot be the same queue. |
| options         | Optional subscriber properties. <code>NULL</code> if there are none. Typically these are lesser used configuration properties supported by the messaging system.                                                                                                                                                                                                                                                                    |

### Usage Notes

#### See Also:

"Handling Arbitrary Payload Types Using Message Transformations", in *Oracle Database Advanced Queuing User's Guide* for more information regarding message conversion and transformation

If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Database Advanced Queuing queues. Otherwise the native Oracle Database Advanced Queuing interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `NULL`.

#### See Also:

For additional information regarding subscriber options

- "WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide*
- "TIB/Rendezvous System Properties" in *Oracle Database Advanced Queuing User's Guide*

### OUTBOUND\_PROPAGATION Subscribers

The parameters for a subscriber used for outbound propagation are interpreted as follows:

- `queue_name` specifies the local Oracle Database Advanced Queuing queue that is the propagation source. This must have a syntax of `schema.queue`.
- `destination` specifies the foreign queue to which messages are propagated. This must have a syntax of `registered_queue@message_link`.

- `rule` specifies an optional Oracle Database Advanced Queuing subscriber rule if the native Oracle Database Advanced Queuing interface is used, or a JMS selector if the Oracle JMS interface is used. If `NULL`, then no rule or selector is used.
- `transformation` specifies the transformation used to convert the Oracle Database Advanced Queuing payload to an ADT defined by Messaging Gateway.

Messaging Gateway propagation dequeues messages from the Oracle Database Advanced Queuing queue using the transformation to convert the Oracle Database Advanced Queuing payload to a known ADT defined by Messaging Gateway. The message is then enqueued in the foreign messaging system based on the Messaging Gateway ADT.

- `exception_queue` specifies the name of a local Oracle Database Advanced Queuing queue to which messages are moved if an exception occurs. This must have a syntax of `schema.queue`.

If the native Oracle Database Advanced Queuing interface is used, then a subscriber will be added to the Oracle Database Advanced Queuing queue when this procedure is called, whether or not Messaging Gateway is running. The local subscriber will be of the form `sys.aq$_agent('MGW_subscriber_id', NULL, NULL)`.

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a JMS durable subscriber with the name of `MGW_subscriber_id`. If the agent is not running when this procedure is called, then the durable subscriber will be created the next time the agent starts.

The exception queue has the following caveats:

- The user is responsible for creating the Oracle Database Advanced Queuing queue to be used as the exception queue.
- The payload type of the source and exception queue must match.
- The exception queue must be created as a queue type of `DBMS_AQADM.NORMAL_QUEUE` rather than `DBMS_AQADM.EXCEPTION_QUEUE`. Enqueue restrictions prevent Messaging Gateway propagation from using an Oracle Database Advanced Queuing queue of type `EXCEPTION_QUEUE` as a Messaging Gateway exception queue.

#### INBOUND\_PROPAGATION Subscribers

The parameters for a subscriber used for inbound propagation are interpreted as follows:

- `queue_name` specifies the foreign queue that is the propagation source. This must have a syntax of `registered_queue@message_link`.
- `destination` specifies the local Oracle Database Advanced Queuing queue to which messages are propagated. This must have a syntax of `schema.queue`.
- `rule` specifies an optional subscriber rule that is valid for the foreign messaging system. This is `NULL` if no rule is needed.
- `transformation` specifies the transformation used to convert an ADT defined by Messaging Gateway to the Oracle Database Advanced Queuing payload type.

Messaging Gateway propagation dequeues messages from the foreign messaging system and converts the message body to a known ADT defined by Messaging Gateway. The transformation is used to convert the Messaging Gateway ADT to an Oracle Database Advanced Queuing payload type when the message is enqueued to the Oracle Database Advanced Queuing queue.

- `exception_queue` specifies the name of a foreign queue to which messages are moved if an exception occurs. This must have a syntax of `registered_queue@message_link`.

Whether or not a subscriber is needed depends on the requirements of the non-Oracle messaging system. If a durable subscriber is necessary, then it will be created by the Messaging Gateway agent. If the agent is not running at the time this procedure is called, then the creation of the subscriber on the non-Oracle messaging system will occur when the agent next starts.

The exception queue has the following caveats:

- The exception queue must be a registered non-Oracle queue.
- The source and exception queues must use the same messaging system link.

## 113.5.2 ALTER\_AGENT Procedures

This procedure configures Messaging Gateway agent parameters.

### Syntax

```
DBMS_MGWADM.ALTER_AGENT (
    max_memory      IN  BINARY_INTEGER DEFAULT NULL,
    max_threads     IN  BINARY_INTEGER DEFAULT NULL,
    service         IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );

DBMS_MGWADM.ALTER_AGENT (
    agent_name      IN  VARCHAR2,
    username        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    password        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    database        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    conntype        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    max_memory      IN  PLS_INTEGER DEFAULT NULL,
    max_threads     IN  PLS_INTEGER DEFAULT NULL,
    service         IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    initfile        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
    comment         IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

### Parameters

**Table 113-21 ALTER\_AGENT Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max_memory  | The maximum heap size, in MB, used by the Messaging Gateway agent. If it is <code>NULL</code> , then the current value is unchanged.                                                                                                                                                                                                                                                                                                                                                   |
| max_threads | The number of messaging threads that the Messaging Gateway agent creates. If it is <code>NULL</code> , then the current value is unchanged. The maximum value of <code>max_threads</code> is limited to 128.                                                                                                                                                                                                                                                                           |
| service     | Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means that the Messaging Gateway agent will run on only those database instances that are assigned to the service. If <code>NULL</code> , the job class used by this agent will be altered to belong to the default service which is mapped to every instance. If <code>DBMS_MGWADM.NO_CHANGE</code> , the current value is unchanged. |
| agent_name  | Identifies the Messaging Gateway agent.<br><code>DBMS_MGWADM.DEFAULT_AGENT</code> specifies the default agent.                                                                                                                                                                                                                                                                                                                                                                         |

**Table 113-21 (Cont.) ALTER\_AGENT Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| username  | Specifies the username used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. If a username is specified then a password must also be specified.                                                                                                                          |
| password  | Specifies the password used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. A password must be specified if a username is specified.                                                                                                                                    |
| database  | Specifies the database connect string used for connections to the Oracle Database. NULL indicates that a local connection should be used. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. Oracle strongly recommends that a connect string, rather than NULL, be specified. Usually it will be a net service name from tnsnames.ora. |
| conntype  | Specifies the type of connection to the Oracle Database, DBMS_MGWADM.JDBC_OCI or DBMS_MGWADM.JDBC_THIN. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.                                                                                                                                                                              |
| initfile  | Specifies a Messaging Gateway initialization file used by this agent. NULL indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.                                                                             |
| comment   | Optional comments for this agent. NULL if a comment is not desired. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.                                                                                                                                                                                                                  |

#### Usage Notes

- Default values for these configuration parameters are set when the Messaging Gateway agent is installed.
- Changes to the `max_memory` and `max_threads` parameters take effect the next time the Messaging Gateway agent is active. If the Messaging Gateway agent is currently active, then it must be shut down and restarted for the changes to take effect.
- The `service` parameter is used to set an Oracle Scheduler job class attribute. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is NULL, the job class will belong to an internal service that is mapped to all instances.
- The `username`, `password`, and `database` parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the user and grant it the role `MGW_AGENT_ROLE`.

## 113.5.3 ALTER\_JOB Procedure

This procedure alters the properties of a propagation job.

#### Syntax

```
DBMS_MGWADM.ALTER_JOB (
  job_name      IN  VARCHAR2,
  rule          IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  transformation IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
```

```
exception_queue IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
poll_interval IN PLS_INTEGER DEFAULT 0,
options IN SYS.MGW_PROPERTIES DEFAULT NULL,
comments IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

## Parameters

**Table 113-22 ALTER\_JOB Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job_name        | Identifies the propagation job                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| rule            | Specifies an optional subscription rule used to dequeue messages from the propagation source. The syntax and interpretation of this parameter depend on the propagation type. A <code>NULL</code> value indicates that no subscription rule is needed. If <code>DBMS_MGWADM.NO_CHANGE</code> , then the current value is unchanged.                                                                                                                                                                                                                                                                                                                                                                                                              |
| transformation  | Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for <code>propagation_type</code> .<br>A <code>NULL</code> value indicates that no transformation is needed. If <code>DBMS_MGWADM.NO_CHANGE</code> , the current value is unchanged.                                                                                                                                                                                                                                                                                                                                                              |
| exception_queue | Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. In cases in which no exception queue is associated with the job, propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the propagation type.<br>A <code>NULL</code> value indicates that no exception queue is used. If <code>DBMS_MGWADM.NO_CHANGE</code> , the current value is unchanged.                                                                                                                                                                                                                                                                |
| poll_interval   | Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available.<br>Values: <code>NULL</code> , 0, or value > 0: <ul style="list-style-type: none"> <li>If zero (default), the current value will not be changed.</li> <li>If <code>NULL</code>, the current value will be reset and the Messaging Gateway default polling interval will be used. The default polling interval is 5 seconds and can be overridden by the Messaging Gateway initialization file.</li> </ul> |
| options         | Optional job properties. If <code>NULL</code> , no options will be changed. If not <code>NULL</code> , then the properties specified in this list are combined with the current optional properties to form a new set of job options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| comments        | An optional comment for this agent, or <code>NULL</code> if one is not desired. If <code>DBMS_MGWADM.NO_CHANGE</code> , the current value will not be changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Usage Notes

- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

- The subscriber rule cannot be altered when propagating from a JMS source. Instead, the propagation job must be dropped and re-created with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.
- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `DBMS_MGWADM.NO_CHANGE` (the default value).
- The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner; add a new property, replace an existing property, remove an existing property or remove all properties.

 **Note:**

- [SYS.MGW\\_PROPERTY Object Type](#) for more information about the options parameter
- [OUTBOUND\\_PROPAGATION Jobs](#) for outbound propagation parameter interpretation
- [INBOUND\\_PROPAGATION Jobs](#) for inbound propagation parameter interpretation

## 113.5.4 ALTER\_MSGSYSTEM\_LINK Procedure for TIB/Rendezvous

This procedure alters the properties of a TIB/Rendezvous messaging system link.

### Syntax

```
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (
    linkname      IN  VARCHAR2,
    properties     IN  SYS.MGW_TIBRV_PROPERTIES,
    options        IN  SYS.MGW_PROPERTIES DEFAULT NULL,
    comment        IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

### Parameters

**Table 113-23 ALTER\_MSGSYSTEM\_LINK Procedure Parameters for TIB/Rendezvous**

| Parameters | Description                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linkname   | The messaging system link name                                                                                                                                                                                  |
| properties | Basic properties for a TIB/Rendezvous messaging system link. If NULL, then no link properties will be changed.                                                                                                  |
| options    | Optional link properties. If NULL, then no options will be changed. If not NULL, then the properties specified in this list are combined with the current options properties to form a new set of link options. |
| comment    | A user-specified description, or NULL if one is not desired. If <code>DBMS_MGWADM.NO_CHANGE</code> , then the current value will not be changed.                                                                |

## Usage Notes

To retain an existing value for a messaging link property with a `VARCHAR2` datatype, specify `DBMS_MGWADM.NO_CHANGE` for that particular property. To preserve an existing value for a property of another datatype, specify `NULL` for that property.

The `options` parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

### See Also:

[SYS.MGW\\_PROPERTIES Object Type](#)

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

## 113.5.5 ALTER\_MSGSYSTEM\_LINK Procedure for WebSphere MQ

This procedure alters the properties of a WebSphere MQ messaging system link.

### Syntax

```
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (  
    linkname    IN    VARCHAR2,  
    properties  IN    SYS.MGW_MQSERIES_PROPERTIES,  
    options     IN    SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment     IN    VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE);
```

### Parameters

**Table 113-24 ALTER\_MSGSYSTEM\_LINK Procedure Parameters for WebSphere MQ**

| Parameters | Description                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linkname   | The messaging system link name                                                                                                                                                                                                   |
| properties | Basic properties for a WebSphere MQ messaging system link. If it is <code>NULL</code> , then no link properties are changed.                                                                                                     |
| options    | Optional link properties. <code>NULL</code> if no options are changed. If not <code>NULL</code> , then the properties specified in this list are combined with the current options properties to form a new set of link options. |

**Table 113-24 (Cont.) ALTER\_MSGSYSTEM\_LINK Procedure Parameters for WebSphere MQ**

| Parameters | Description                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------|
| comment    | An optional description or NULL if not desired. If DBMS_MGWADM.NO_CHANGE is specified, then the current value is not changed. |

### Usage Notes

To retain an existing value for a messaging link property with a VARCHAR2 datatype, specify DBMS\_MGWADM.NO\_CHANGE for that particular property. To preserve an existing value for a property of another datatype, specify NULL for that property.

The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

#### See Also:

[SYS.MGW\\_PROPERTIES Object Type](#)

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

#### See Also:

"WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

## 113.5.6 ALTER\_PROPAGATION\_SCHEDULE Procedure

This procedure alters a propagation schedule.

#### Note:

This subprogram has been deprecated as a result of improved technology (see [ALTER\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.ALTER_PROPAGATION_SCHEDULE (  
    schedule_id  IN VARCHAR2,  
    duration     IN NUMBER DEFAULT NULL,
```

```
next_time    IN VARCHAR2 DEFAULT NULL,  
latency      IN NUMBER DEFAULT NULL);
```

## Parameters

**Table 113-25 ALTER\_PROPAGATION\_SCHEDULE Procedure Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schedule_id</code> | Identifies the propagation schedule to be altered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>duration</code>    | Reserved for future use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>next_time</code>   | Reserved for future use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>latency</code>     | <p>Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available.</p> <p>Values: NULL or value &gt; 0. If <code>latency</code> is NULL, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds, but it can be overridden by the Messaging Gateway initialization file.</p> |

## Usage Notes

This procedure always overwrites the existing value for each parameter. If a given parameter is not specified, then the existing values are overwritten with the default value.

## 113.5.7 ALTER\_SUBSCRIBER Procedure

This procedure alters the parameters of a subscriber used to consume messages from a source queue for propagation to a destination.

### Note:

This subprogram has been deprecated as a result of improved technology (see [ALTER\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

## Syntax

```
DBMS_MGWADM.ALTER_SUBSCRIBER (  
  subscriber_id  IN VARCHAR2,  
  rule           IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  transformation IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  exception_queue IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  options        IN SYS.MGW_PROPERTIES DEFAULT NULL );
```

## Parameters

**Table 113-26 ALTER\_SUBSCRIBER Procedure Parameters**

| Parameter                  | Description                             |
|----------------------------|-----------------------------------------|
| <code>subscriber_id</code> | Identifies the subscriber to be altered |

**Table 113-26 (Cont.) ALTER\_SUBSCRIBER Procedure Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rule</code>            | Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. The syntax and interpretation of this parameter depend on the subscriber propagation type.<br><br>A <code>NULL</code> value indicates that no subscription rule is needed. If <code>DBMS_MGWADM.NO_CHANGE</code> , then the current value is unchanged.                                                                                                                                                                                               |
| <code>transformation</code>  | Specifies the transformation needed to convert between the Oracle Database Advanced Queuing payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the subscriber propagation type.<br><br>A <code>NULL</code> value indicates that no transformation is needed. If <code>DBMS_MGWADM.NO_CHANGE</code> , then the current value is unchanged.                                                                                                                                                                            |
| <code>exception_queue</code> | Specifies a queue used for exception message logging. This queue must be on the same messaging system as the propagation source. If no exception queue is associated with the subscriber, then propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the subscriber propagation type.<br><br>A <code>NULL</code> value indicates that no exception queue is used. If <code>DBMS_MGWADM.NO_CHANGE</code> , then the current value is unchanged.<br><br>The source queue and exception queue cannot be the same queue. |
| <code>options</code>         | Optional subscriber properties. If <code>NULL</code> , then no options will be changed. If not <code>NULL</code> , then the properties specified in this list are combined with the current optional properties to form a new set of subscriber options.                                                                                                                                                                                                                                                                                                        |

### Usage Notes

If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Database Advanced Queuing queues. Otherwise the native Oracle Database Advanced Queuing interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

When propagating from a JMS source, the subscriber rule cannot be altered. Instead, the subscriber must be removed and added with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `DBMS_MGWADM.NO_CHANGE` (the default value).

The `options` parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

## 113.5.8 CLEANUP\_GATEWAY Procedures

This procedure cleans up Messaging Gateway. The procedure performs cleanup or recovery actions that may be needed when Messaging Gateway is left in some abnormal or unexpected condition. The `MGW_GATEWAY` view lists Messaging Gateway status and configuration information that pertains to the cleanup actions.

### Syntax

```
DBMS_MGWADM.CLEANUP_GATEWAY (
    action          IN    BINARY_INTEGER,
    sarg            IN    VARCHAR2 DEFAULT NULL);
```

```
DBMS_MGWADM.CLEANUP_GATEWAY (
    agent_name      IN    VARCHAR2,    action          IN    BINARY_INTEGER,    sarg            IN
    VARCHAR2 DEFAULT NULL );
```

### Parameters

**Table 113-27 CLEANUP\_GATEWAY Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action     | The cleanup action to be performed. Values: <ul style="list-style-type: none"> <li>• <code>DBMS_MGWADM.CLEAN_STARTUP_STATE</code> for Messaging Gateway start up state recovery</li> <li>• <code>DBMS_MGWADM.CLEAN_LOG_QUEUES</code> for log queue cleanup</li> <li>• <code>DBMS_MGWADM.RESET_SUB_MISSING_LOG_REC</code> for propagation job recovery due to missing log record</li> <li>• <code>DBMS_MGWADM.RESET_SUB_MISSING_MESSAGE</code> for propagation job recovery due to missing message</li> </ul> |
| sarg       | Optional argument whose meaning depends on the value specified for action. This should be NULL if it is not used for the specified action.                                                                                                                                                                                                                                                                                                                                                                   |
| agent_name | Identifies the Messaging Gateway agent.<br><code>DBMS_MGWADM.DEFAULT_AGENT</code> specifies the default agent.                                                                                                                                                                                                                                                                                                                                                                                               |

## Usage Notes

### CLEAN\_STARTUP\_STATE

`sarg` is not used and must be `NULL`.

The `CLEAN_STARTUP_STATE` action recovers Messaging Gateway to a known state when the Messaging Gateway agent has crashed or some other abnormal event occurs, and Messaging Gateway cannot be restarted. This should be done only when the Messaging Gateway agent has been started but appears to have crashed or has been nonresponsive for an extended period of time.

The `CLEAN_STARTUP_STATE` action may be needed when the `MGW_GATEWAY` view shows that the `AGENT_STATUS` value is something other than `NOT_STARTED` or `START_SCHEDULED`, and the `AGENT_PING` value is `UNREACHABLE` for an extended period of time.

If the `AGENT_STATUS` value is `BROKEN`, then the Messaging Gateway agent cannot be started until the problem has been resolved and the `CLEAN_STARTUP_STATE` action used to reset the agent status. A `BROKEN` status can indicate that the Messaging Gateway start job detected a Messaging Gateway agent already running. This condition that should never occur under normal use.

Cleanup tasks include:

- Removing the Scheduler job used to start the external Messaging Gateway agent process.
- Setting certain configuration information to a known state. For example, setting the agent status to `NOT_STARTED`.

Execution of this command fails if:

- The agent status is `NOT_STARTED` or `START_SCHEDULED`.
- No shutdown attempt has been made prior to calling this procedure, except if the agent status is `STARTING`.
- The Messaging Gateway agent is successfully contacted.

The assumption is that the agent is active, and this procedure fails. If the agent does not respond after several attempts have been made, then the cleanup tasks are performed. This procedure takes at least several seconds and possibly up to one minute. This is expected behavior under conditions where this particular cleanup action is appropriate and necessary.

#### Note:

Terminate any Messaging Gateway agent process that may still be running after a `CLEAN_STARTUP_STATE` action has been successfully performed. This should be done before calling `DBMS_MGWADM.STARTUP` to start Messaging Gateway. The process is usually named `extprocmgwextproc`.

### CLEAN\_LOG\_QUEUES

`sarg` is not used and must be `NULL`.

The Messaging Gateway agent will clean log queues for all configured messaging system links. The agent will temporarily stop all propagation activity and then remove all obsolete and

bad log records from the log queues for all links. The procedure will fail if the Messaging Gateway agent is not running.

This cleanup action is automatically performed each time the Messaging Gateway agent is started.

**Note:**

The `CLEAN_LOG_QUEUES` action is performed only on agent startup. If this procedure is called when the agent is running, then the Messaging Gateway agent ignores it.

## RESET\_SUB\_MISSING\_LOG\_REC

`sarg` specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be `NULL`.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing log record. The agent will reset the source and destination log records. The procedure will fail if the Messaging Gateway agent is not running.

**Note:**

If the messages in the source queue had already been propagated to the destination queue, then this action may result in duplicate messages.

## RESET\_SUB\_MISSING\_MESSAGE

`sarg` specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be `NULL`.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing persistent source message. The agent will treat the message as a non-persistent message and continue processing that propagation job. The procedure will fail if the Messaging Gateway agent is not running.

## 113.5.9 CREATE\_AGENT Procedure

This procedure creates a Messaging Gateway agent that will be used to process propagation jobs.

### Syntax

```
DBMS_MGWADM.CREATE_AGENT (
  agent_name      IN   VARCHAR2,
  username        IN   VARCHAR2 DEFAULT NULL,
  password        IN   VARCHAR2 DEFAULT NULL,
  database        IN   VARCHAR2 DEFAULT NULL,
  conntype        IN   VARCHAR2 DEFAULT DBMS_MGWADM.JDBC_OCI,
  max_memory      IN   PLS_INTEGER DEFAULT 64,
  max_threads     IN   PLS_INTEGER DEFAULT 1,
  service         IN   VARCHAR2 DEFAULT NULL,
  initfile        IN   VARCHAR2 DEFAULT NULL,
  comment         IN   VARCHAR2  DEFAULT NULL );
```

## Parameters

**Table 113-28 CREATE\_AGENT Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| agent_name  | A name used to identify the agent                                                                                                                                                                                                                                                                                                                                                   |
| username    | Specifies the username used for connections to the Oracle Database                                                                                                                                                                                                                                                                                                                  |
| password    | Specifies the password used for connections to the Oracle Database. A password must be specified if a username is specified.                                                                                                                                                                                                                                                        |
| database    | Specifies the database connect string used for connections to the Oracle Database. <code>NULL</code> indicates that a local connection should be used. A value can be specified only if username is specified. Oracle strongly recommends that a connect string, rather than <code>NULL</code> be specified. Usually it will be a net service name from <code>tnsnames.ora</code> . |
| conntype    | Specifies the type of connection to the Oracle Database. Values: <code>DBMS_MGWADM.JDBC_OCI</code> , <code>DBMS_MGWADM.JDBC_THIN</code>                                                                                                                                                                                                                                             |
| max_memory  | Specifies the maximum heap size, in MB, used by the Messaging Gateway agent                                                                                                                                                                                                                                                                                                         |
| max_threads | Specifies the number of messaging threads that the Messaging Gateway agent creates. This determines the number of propagation jobs that the agent can concurrently process. The maximum value of <code>max_threads</code> is limited to 128.                                                                                                                                        |
| service     | Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means that the Messaging Gateway agent will only run on those database instances that are assigned to the service. If <code>NULL</code> , then the job class will belong to the default service which is mapped to every instance.  |
| initfile    | Specifies a Messaging Gateway initialization file used by this agent. <code>NULL</code> indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file.                                                                                                                                                               |
| comment     | An optional comment for this agent. <code>NULL</code> if one is not desired.                                                                                                                                                                                                                                                                                                        |

## Usage Notes

- The Messaging Gateway automatically configures a default agent when Messaging Gateway is installed. The name of the default agent is `DEFAULT_AGENT`. This procedure can be used to create additional agents.
- The `username`, `password`, and `database` parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the database user and grant it the role `MGW_AGENT_ROLE`. It is not mandatory that the connection information be specified when this procedure is called but it must be set before the agent can be started.
- The `service` parameter is used to create an Oracle Scheduler job class. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is `NULL`, the job class will belong to an internal service that is mapped to all instances.

## 113.5.10 CREATE\_JOB Procedure

This procedure creates a job used to propagate message from a source to a destination.

### Syntax

```
DBMS_MGWADM.CREATE_JOB (
    job_name          IN   VARCHAR2,
    propagation_type  IN   PLS_INTEGER,
    source            IN   VARCHAR2,
    destination       IN   VARCHAR2,
    rule             IN   VARCHAR2 DEFAULT NULL,
    transformation    IN   VARCHAR2 DEFAULT NULL,
    exception_queue   IN   VARCHAR2 DEFAULT NULL,
    poll_interval     IN   PLS_INTEGER DEFAULT NULL,
    options           IN   SYS.MGW_PROPERTIES DEFAULT NULL,
    enabled          IN   BOOLEAN DEFAULT TRUE,
    comments          IN   VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 113-29 CREATE\_JOB Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job_name         | A user defined name to identify the propagation job                                                                                                                                                                                                                                                                                                                                                             |
| propagation_type | Specifies the type of message propagation. <ul style="list-style-type: none"> <li>DBMS_MGWADM.OUTBOUND_PROPAGATION for Oracle Streams AQ to non-Oracle propagation.</li> <li>DBMS_MGWADM.INBOUND_PROPAGATION for non-Oracle to Oracle Streams AQ propagation.</li> </ul>                                                                                                                                        |
| source           | Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                                                                                                                                                             |
| destination      | Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                                                                                                                                                           |
| rule             | Specifies an optional subscription rule used to dequeue messages from the source queue. This should be NULL if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for propagation_type.                                                                                                                                                                           |
| transformation   | Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for propagation_type.<br><br>If no transformation is specified the Oracle Streams AQ payload type must be supported by Messaging Gateway.                                                                        |
| exception_queue  | Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. If NULL, an exception queue will not be used and propagation will stop if a problem occurs. The syntax and interpretation of this parameter depend on the value specified for propagation_type.<br><br>The source queue and exception queue cannot be the same queue. |

**Table 113-29 (Cont.) CREATE\_JOB Procedure Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>poll_interval</code> | Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available.<br>Values: <code>NULL</code> or value <code>&gt; 0</code> . If <code>NULL</code> , then the Messaging Gateway default polling interval will be used. The default polling interval is 5 seconds and can be overridden by the Messaging Gateway initialization file. |
| <code>options</code>       | Optional job properties, <code>NULL</code> if there are none. Typically these are lesser used configuration properties supported by the messaging system.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>enabled</code>       | Specifies whether this propagation job is enabled after creation. Values: <code>TRUE</code> , <code>FALSE</code> . <ul style="list-style-type: none"><li>If <code>TRUE</code> (default), the job will be enabled after it is created.</li><li>If <code>FALSE</code>, the job will be disabled after it is created. A propagation job must be enabled and the Messaging Gateway agent running before messages can be propagated.</li></ul>                                                                                                                                                                 |
| <code>comments</code>      | An optional comment for this job. <code>NULL</code> if one is not desired.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Usage Notes

- The job must be enabled and Messaging Gateway agent started in order for messages to be propagated.
- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.
- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `NULL`.

### OUTBOUND\_PROPAGATION Jobs

The parameters for an outbound propagation job are interpreted as follows:

- `source` specifies the local Oracle Streams AQ queue that is the propagation source. This must have syntax of `schema.queue`. This can be either a multiple consumer queue or a single consumer queue.
- `destination` specifies the non-Oracle queue to which messages are propagated. This must have syntax of `registered_queue@message_link`.
- `rule` specifies an optional Oracle Streams AQ subscriber rule if the native Oracle Stream AQ interface is used, or a JMS selector if the Oracle JMS interface is used. If `NULL`, then no rule or selector is used. This parameter must be `NULL` if the native Oracle Stream AQ interface is used and the propagation source is a single consumer queue.
- `transformation` specifies the transformation used to convert the Oracle Streams AQ payload to an ADT defined by Messaging Gateway. The full transformation name (`schema.name`) should be used if one is specified.

Messaging Gateway propagation dequeues messages from the Oracle Streams AQ queue using the transformation to convert the Oracle Streams AQ payload to a known ADT defined by Messaging Gateway. The message is then enqueued in the non-Oracle messaging system based on the Messaging Gateway ADT.

- `exception_queue` specifies the name of a local Oracle Streams AQ queue to which messages are moved if an exception occurs. The syntax must be `schema.queue`.

If the native Oracle Streams AQ interface is used and the source is a multiple consumer queue, then a subscriber will be added to the Oracle Streams AQ queue when this procedure is called, whether or not the Messaging Gateway agent is running. The local subscriber will be of the form `sys.aq$_agent('MGW_job_name', NULL, NULL)`.

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a JMS durable subscriber with the name of `MGW_job_name`. If the agent is not running when this procedure is called, then the durable subscriber will be created the next time the agent starts.

The exception queue has the following conditions:

- The user is responsible for creating the Oracle Streams AQ queue to be used as the exception queue.
- The payload type of the source queue and exception queue must match.
- The exception queue must be created as a queue type of `DBMS_AQADM.NORMAL_QUEUE`. Enqueue restrictions prevent Messaging Gateway from using an Oracle Streams AQ queue of type `DBMS_AQADM.EXCEPTION_QUEUE` as a Messaging Gateway exception queue.

#### INBOUND\_PROPAGATION Jobs

The parameters for an inbound propagation job are interpreted as follows:

- `source` specifies the non-Oracle queue that is the propagation source. The syntax must be `registered_queue@message_link`.
- `destination` specifies the local Oracle Streams AQ queue to which messages are propagated. The syntax must be `schema.queue`.
- `rule` specifies an optional subscriber rule that is valid for the non-Oracle messaging system. This should be `NULL` if no rule is needed.
- `transformation` specifies the transformation used to convert an ADT defined by Messaging Gateway to the Oracle Streams AQ payload type. The full transformation name (`schema.name`) should be used if one is specified

Messaging Gateway propagation dequeues messages from the non-Oracle messaging system and converts the message body to a known ADT defined by Messaging Gateway. The transformation is used to convert the Messaging Gateway ADT to an Oracle Streams AQ payload type when the message is enqueued to the Oracle Streams AQ queue.

- `exception_queue` specifies the name of a registered non-Oracle queue to which messages are moved if an exception occurs. The syntax must be `registered_queue@message_link`.

Whether or not a subscriber is needed for the source queue depends on the requirements of the non-Oracle messaging system. If a durable subscriber is necessary, then the Messaging Gateway agent will create it. If the agent is not running when this procedure is called, then the subscriber will be created on the non-Oracle messaging system the next time the agent starts.

The exception queue has the following conditions:

- The exception queue must be a registered non-Oracle queue.

- The source queue and exception queue must use the same messaging system link.

### 113.5.11 CREATE\_MSGSYSTEM\_LINK Procedures for TIB/Rendezvous

This procedure creates a link to a TIB/Rendezvous messaging system.

#### Syntax

```
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (  
    linkname      IN  VARCHAR2,  
    properties    IN  SYS.MGW_TIBRV_PROPERTIES,  
    options       IN  SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment       IN  VARCHAR2 DEFAULT NULL );  
  
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (  
    linkname      IN  VARCHAR2,  
    agent_name    IN  VARCHAR2,  
    properties    IN  SYS.MGW_TIBRV_PROPERTIES,  
    options       IN  SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment       IN  VARCHAR2 DEFAULT NULL );
```

#### Parameters

**Table 113-30    CREATE\_MSGSYSTEM\_LINK Procedure Parameters for TIB/Rendezvous**

| Parameter  | Description                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linkname   | A user-defined name to identify this messaging system link                                                                                                                   |
| properties | Basic properties of a TIB/Rendezvous messaging system link.                                                                                                                  |
| options    | Optional link properties. NULL if there are none. These are less frequently used configuration properties supported by the messaging system                                  |
| comment    | A user-specified description. NULL if one is not desired.                                                                                                                    |
| agent_name | Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link.<br>DBMS_MGWADM.DEFAULT_AGENT specifies the default agent. |

#### Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

 **See Also:**

"TIB/Rendezvous System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

## 113.5.12 CREATE\_MSGSYSTEM\_LINK Procedures for WebSphere MQ

This procedure creates a messaging system link to a WebSphere MQ messaging system.

### Syntax

```
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(  
    linkname      IN VARCHAR2,  
    properties    IN SYS.MGW_MQSERIES_PROPERTIES,  
    options       IN SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment       IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(  
    linkname      IN VARCHAR2,  
    agent_name    IN VARCHAR2,  
    properties    IN SYS.MGW_MQSERIES_PROPERTIES,  
    options       IN SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment       IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 113-31** CREATE\_MSGSYSTEM\_LINK Procedure Parameters for WebSphere MQ

| Parameter  | Description                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| linkname   | A user-defined name to identify the messaging system link                                                                                                                    |
| properties | Basic properties of a WebSphere MQ messaging system link                                                                                                                     |
| options    | Optional link properties. NULL if there are none. These are less frequently used configuration properties supported by the messaging system.                                 |
| comment    | A user-specified description. NULL if one is not desired                                                                                                                     |
| agent_name | Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link.<br>DBMS_MGWADM.DEFAULT_AGENT specifies the default agent. |

### Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

#### See Also:

"WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

## 113.5.13 DB\_CONNECT\_INFO Procedure

This deprecated procedure configures connection information used by the Messaging Gateway default agent for connections to Oracle Database.

### Note:

This subprogram has been deprecated as a result of improved technology (see [ALTER\\_AGENT Procedures](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.DB_CONNECT_INFO (  
    username      IN VARCHAR2,  
    password      IN VARCHAR2,  
    database      IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 113-32 DB\_CONNECT\_INFO Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| username  | The username used for connections to Oracle Database. NULL is not allowed                                                                                                                                                                                        |
| password  | The password used for connections to Oracle Database. NULL is not allowed                                                                                                                                                                                        |
| database  | The database connect string used by the Messaging Gateway agent. NULL indicates that a local connection should be used.<br>Oracle strongly recommends that a not NULL value be specified. Usually it will be a net service name from <code>tnsnames.ora</code> . |

### Usage Notes

The Messaging Gateway agent connects to Oracle Database as the user configured by this procedure. An Oracle administrator should create the user, grant it the role `MGW_AGENT_ROLE`, and then call this procedure to configure Messaging Gateway. Role `MGW_AGENT_ROLE` is used to grant this user special privileges needed to access Messaging Gateway configuration information stored in the database, enqueue or dequeue messages to and from Oracle Database Advanced Queuing queues, and perform certain Oracle Database Advanced Queuing administration tasks.

## 113.5.14 DISABLE\_JOB Procedure

This procedure disables a propagation job.

### Syntax

```
DBMS_MGWADM.DISABLE_JOB (  
    job_name      IN VARCHAR2);
```

## Parameters

**Table 113-33** DISABLE\_JOB Procedure Parameters

| Parameter | Description                    |
|-----------|--------------------------------|
| job_name  | Identifies the propagation job |

## 113.5.15 DISABLE\_PROPAGATION\_SCHEDULE Procedure

This **deprecated procedure** disables a propagation schedule.

### Note:

This subprogram has been deprecated as a result of improved technology (see [DISABLE\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

## Syntax

```
DBMS_MGWADM.DISABLE_PROPAGATION_SCHEDULE (  
    schedule_id IN VARCHAR2);
```

## Parameters

**Table 113-34** DISABLE\_PROPAGATION\_SCHEDULE Procedure Parameters

| Parameter   | Description                                        |
|-------------|----------------------------------------------------|
| schedule_id | Identifies the propagation schedule to be disabled |

## 113.5.16 ENABLE\_JOB Procedure

This procedure enables a propagation job.

## Syntax

```
DBMS_MGWADM.ENABLE_JOB (  
    job_name IN VARCHAR2 );
```

## Parameters

**Table 113-35** ENABLE\_JOB Procedure Parameters

| Parameter | Description                    |
|-----------|--------------------------------|
| job_name  | Identifies the propagation job |

## 113.5.17 ENABLE\_PROPAGATION\_SCHEDULE Procedure

This deprecated procedure enables a propagation schedule.

### Note:

This subprogram has been deprecated as a result of improved technology (see [ENABLE\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.ENABLE_PROPAGATION_SCHEDULE (
    schedule_id IN VARCHAR2 );
```

### Parameters

**Table 113-36** ENABLE\_PROPAGATION\_SCHEDULE Procedure Parameters

| Parameter   | Description                                       |
|-------------|---------------------------------------------------|
| schedule_id | Identifies the propagation schedule to be enabled |

## 113.5.18 REGISTER\_FOREIGN\_QUEUE Procedure

This procedure registers a non-Oracle queue entity in Messaging Gateway.

### Syntax

```
DBMS_MGWADM.REGISTER_FOREIGN_QUEUE (
    name           IN VARCHAR2,
    linkname       IN VARCHAR2,
    provider_queue IN VARCHAR2 DEFAULT NULL,
    domain         IN INTEGER DEFAULT NULL,
    options        IN SYS.MGW_PROPERTIES DEFAULT NULL,
    comment        IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 113-37** REGISTER\_FOREIGN\_QUEUE Procedure Parameters

| Parameters     | Description                                                                                                                                                          |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name           | The registered queue name. This name identifies the foreign queue within Messaging Gateway and need not match the name of the queue in the foreign messaging system. |
| linkname       | The link name for the messaging system on which this queue exists                                                                                                    |
| provider_queue | The message provider (native) queue name. If NULL, then the value provided for the name parameter is used as the provider queue name.                                |

**Table 113-37 (Cont.) REGISTER\_FOREIGN\_QUEUE Procedure Parameters**

| Parameters | Description                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| domain     | The domain type of the queue. NULL means the domain type is automatically determined based on the messaging system of the queue. DBMS_MGWADM.DOMAIN_QUEUE is for a queue (point-to-point model). DBMS_MGWADM.DOMAIN_TOPIC is for a topic (publish-subscribe model). |
| options    | Optional queue properties                                                                                                                                                                                                                                           |
| comment    | A user-specified description. Can be NULL.                                                                                                                                                                                                                          |

**Usage Notes**

This procedure does not create the physical queue in the non-Oracle messaging system. The non-Oracle queue must be created using the administration tools for that messaging system.

**See Also:**

For more information when registering queues for the WebSphere MQ messaging system or the TIB/Rendezvous messaging system, specifically "Optional Foreign Queue Configuration Properties" in *Oracle Database Advanced Queuing User's Guide*.

## 113.5.19 REMOVE\_AGENT Procedure

This procedure removes a Messaging Gateway agent.

**Syntax**

```
DBMS_MGWADM.REMOVE_AGENT(  
    agent_name    IN    VARCHAR2 );
```

**Parameters****Table 113-38 REMOVE\_AGENT Procedure Parameters**

| Parameters | Description                            |
|------------|----------------------------------------|
| agent_name | Identifies the Messaging Gateway agent |

**Usage Notes**

All messaging system links associated with this Messaging Gateway agent must be removed and the agent must be stopped before it can be removed. The Messaging Gateway default agent cannot be removed.

## 113.5.20 REMOVE\_JOB Procedure

This procedure removes a propagation job.

### Syntax

```
DBMS_MGWADM.REMOVE_JOB(  
    job_name    IN    VARCHAR2,    force    IN    PLS_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE);
```

### Parameters

**Table 113-39 REMOVE\_JOB Procedure Parameters**

| Parameters | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job_name   | Identifies the propagation job                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| force      | <p>Specifies whether the procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this propagation job.</p> <p>Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE</p> <ul style="list-style-type: none"><li>NO_FORCE (default) means the job is not removed if Messaging Gateway is unable to clean up successfully</li><li>FORCE means the job is removed even though all cleanup actions may not be done</li></ul> |

### Usage Notes

- The Messaging Gateway agent uses various resources of the Oracle Database and the non-Oracle messaging system for its propagation work. These resources need to be released when the job is removed. For example, Messaging Gateway may create a durable subscriber on the source queue that should be removed when the job is removed. Therefore, this procedure should normally be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this job.
- For outbound propagation, a local subscriber is removed from the Oracle Streams AQ queue when the propagation source is a multiple consumer queue.

## 113.5.21 REMOVE\_MSGSYSTEM\_LINK Procedure

This procedure removes a messaging system link for a non-Oracle messaging system.

### Syntax

```
DBMS_MGWADM.REMOVE_MSGSYSTEM_LINK(  
    linkname    IN VARCHAR2);
```

### Parameters

**Table 113-40 REMOVE\_MSGSYSTEM\_LINK Procedure Parameters**

| Parameters | Description                    |
|------------|--------------------------------|
| linkname   | The messaging system link name |

## Usage Notes

All registered queues associated with this link must be removed before the messaging system link can be removed. This procedure fails if there is a registered foreign (non-Oracle) queue that references this link.

## 113.5.22 REMOVE\_OPTION Procedure

This procedure removes a Messaging Gateway configuration option. It can be used to remove an agent option, a messaging link option, or a propagation job option.

### Syntax

```
DBMS_MGWADM.REMOVE_OPTION (  
    target_type    IN    PLS_INTEGER,  
    target_name    IN    VARCHAR2,  
    option_name    IN    VARCHAR2);
```

### Parameters

**Table 113-41 REMOVE\_OPTION Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| target_type | Specifies the target type of the Messaging Gateway entity: <ul style="list-style-type: none"><li>DBMS_MGWADM.AGENT_JAVA_PROP to remove a Java System property for a Messaging Gateway agent</li><li>DBMS_MGWADM.MSGLINK_OPTION to remove a messaging link option</li><li>DBMS_MGWADM.JOB_OPTION to remove a propagation job option</li></ul> |
| target_name | Name or identifier of the target. The value for this parameter depends on the value specified for target_type parameter. This must not be NULL.                                                                                                                                                                                              |
| option_name | Option name. This must not be NULL.                                                                                                                                                                                                                                                                                                          |

#### See Also:

[Table 113-10](#) regarding options for the option\_type parameter

## Usage Notes

### DBMS\_MGWADM.AGENT\_JAVA\_PROP Target

The procedure removes an agent option used to set a Java System property when the Messaging Gateway agent is started. The agent must be restarted for the change to take effect.

The parameters are interpreted as follows:

- target\_name specifies the name of the Messaging Gateway agent. DBMS\_MGWADM.DEFAULT\_AGENT can be used for the default agent.
- option\_name specifies the Java System property

- `encrypted` can be either `TRUE` or `FALSE`

#### DBMS\_MGWADM.MSGLINK\_OPTION Target

The procedure removes a single option for a Messaging Gateway messaging system link. This is equivalent to calling `DBMS_MGWADM.ALTER_MSGSYSTEM_LINK` and using the `options` parameter to remove an option.

The parameters are interpreted as follows:

- `target_name` specifies the name of the message system link
- `option_name` specifies the option to set
- `encrypted` must be `FALSE`

#### DBMS\_MGWADM.JOB\_OPTION Target

The procedure removes a single option for a Messaging Gateway propagation job. This is equivalent to calling `DBMS_MGWADM.ALTER_JOB` and using the `options` parameter to remove an option.

The parameters are interpreted as follows:

- `target_name` specifies the name of the propagation job
- `option_name` specifies the option to set
- `encrypted` must be `FALSE`

## 113.5.23 REMOVE\_SUBSCRIBER Procedure

This procedure removes a subscriber used to consume messages from a source queue for propagation to a destination.

### Note:

This subprogram has been deprecated as a result of improved technology (see [REMOVE\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.REMOVE_SUBSCRIBER (  
    subscriber_id IN VARCHAR2,  
    force          IN BINARY_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE );
```

### Parameters

**Table 113-42 REMOVE\_SUBSCRIBER Procedure Parameters**

| Parameter                  | Description                             |
|----------------------------|-----------------------------------------|
| <code>subscriber_id</code> | Identifies the subscriber to be removed |

**Table 113-42 (Cont.) REMOVE\_SUBSCRIBER Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| force     | <p>Specifies whether this procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this subscriber.</p> <p>Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE</p> <ul style="list-style-type: none"><li>• NO_FORCE means the subscriber is not removed if Messaging Gateway is unable to clean up successfully (default)</li><li>• FORCE means the subscriber is removed even though all cleanup actions may not be done</li></ul> |

**Usage Notes**

- The Messaging Gateway agent uses various resources of Oracle Database and the non-Oracle messaging system for its propagation work. These resources are typically associated with each subscriber and need to be released when the subscriber is no longer needed. Therefore, this procedure should only be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this subscriber.
- For outbound propagation, a local subscriber is removed from the Oracle Database Advanced Queuing queue.

## 113.5.24 RESET\_JOB Procedure

This procedure resets the propagation error state for a propagation job.

**Syntax**

```
DBMS_MGWADM.RESET_JOB (  
    job_name    IN    VARCHAR2);
```

**Parameters****Table 113-43 RESET\_JOB Procedure Parameters**

| Parameter | Description                    |
|-----------|--------------------------------|
| job_name  | Identifies the propagation job |

**Usage Notes**

This procedure can be used to reset a propagation job that has been set to a failed state and propagation activities have been stopped. The administrator should correct the problem and then call this procedure to allow the agent to retry the propagation job. The `STATUS` field of the `MGW_JOBS` view indicates the job status.

## 113.5.25 RESET\_SUBSCRIBER Procedure

This procedure resets the propagation error state for a subscriber.

### Note:

This subprogram has been deprecated as a result of improved technology (see [RESET\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.RESET_SUBSCRIBER (  
    subscriber_id IN VARCHAR2 );
```

### Parameters

**Table 113-44** RESET\_SUBSCRIBER Procedure Parameters

| Parameter     | Description               |
|---------------|---------------------------|
| subscriber_id | Identifies the subscriber |

## 113.5.26 SCHEDULE\_PROPAGATION Procedure

This procedure schedules message propagation from a source to a destination.

The schedule must be enabled and Messaging Gateway started in order for messages to be propagated.

### Note:

This subprogram has been deprecated as a result of improved technology (see [CREATE\\_JOB Procedure](#)), and is retained only for reasons of backward compatibility.

### Syntax

```
DBMS_MGWADM.SCHEDULE_PROPAGATION (  
    schedule_id      IN VARCHAR2,  
    propagation_type IN BINARY_INTEGER,  
    source           IN VARCHAR2,  
    destination      IN VARCHAR2,  
    start_time       IN DATE DEFAULT SYSDATE,  
    duration         IN NUMBER DEFAULT NULL,  
    next_time        IN VARCHAR2 DEFAULT NULL,  
    latency          IN NUMBER DEFAULT NULL);
```

## Parameters

**Table 113-45 SCHEDULE\_PROPAGATION Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>schedule_id</code>      | Specifies a user-defined name that identifies the schedule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>propagation_type</code> | Specifies the type of message propagation.<br>DBMS_MGWADM.OUTBOUND_PROPAGATION is for Oracle Database Advanced Queuing to non-Oracle propagation.<br>DBMS_MGWADM.INBOUND_PROPAGATION is for non-Oracle to Oracle Database Advanced Queuing propagation.                                                                                                                                                                                                                                                                                                                                                                  |
| <code>source</code>           | Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>destination</code>      | Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>start_time</code>       | Reserved for future use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>duration</code>         | Reserved for future use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>next_time</code>        | Reserved for future use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>latency</code>          | Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available.<br>Values: NULL or value > 0. If <code>latency</code> is NULL, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds but it can be overridden by the Messaging Gateway initialization file. |

## Usage Notes

For outbound propagation, parameters are interpreted as follows:

- `source` specifies the local Oracle Database Advanced Queuing queue from which messages are propagated. This must have a syntax of `schema.queue`.
- `destination` specifies the foreign queue to which messages are propagated. This must have a syntax of `registered_queue@message_link`.

For inbound propagation, parameters are interpreted as follows:

- `source` specifies the foreign queue from which messages are propagated. This must have a syntax of `registered_queue@message_link`.
- `destination` specifies the local Oracle Database Advanced Queuing queue to which messages are propagated. This must have a syntax of `schema.queue`.

The schedule is set to an enabled state when it is created.

## 113.5.27 SET\_LOG\_LEVEL Procedures

This procedure dynamically alters the Messaging Gateway agent logging level. The Messaging Gateway agent must be running.

### Syntax

```
DBMS_MGWADM.SET_LOG_LEVEL (
    log_level    IN    BINARY_INTEGER);

DBMS_MGWADM.SET_LOG_LEVEL (
    agent_name   IN    VARCHAR2,
    log_level    IN    BINARY_INTEGER);
```

### Parameters

**Table 113-46 SET\_LOG\_LEVEL Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_level  | Level at which the Messaging Gateway agent logs information. DBMS_MGWADM.BASIC_LOGGING generates the least information while DBMS_MGWADM.TRACE_DEBUG_LOGGING generates the most information. |
| agent_name | Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.                                                                                               |

## 113.5.28 SET\_OPTION Procedure

This procedure sets a Messaging Gateway configuration option. It can be used to set an agent option, a messaging link option, or a propagation job option.

### Syntax

```
DBMS_MGWADM.SET_OPTION (
    target_type  IN    PLS_INTEGER,
    target_name  IN    VARCHAR2,
    option_name  IN    VARCHAR2,
    option_value IN    VARCHAR2,
    encrypted    IN    BOOLEAN DEFAULT FALSE );
```

## Parameters

**Table 113-47 SET\_OPTION Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                         |
