| quote                | Specifies the quote character for the fields, the quote characters are removed during loading when specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <code>quote: character</code><br>Default value: <code>Null</code> meaning no quote                                                                                                                                                                  |
| recorddelimiter      | Specifies the record delimiter.<br>By default, DBMS_CLOUD tries to automatically find the correct newline character as the delimiter. It first searches the file for the Windows newline character <code>"\r\n"</code> . If it finds the Windows newline character, this is used as the record delimiter for the file. If a Windows newline character is not found, it searches for the UNIX/Linux newline character <code>"\n"</code> and if it finds one it uses it as the record delimiter for the file.<br>Specify this argument explicitly if you want to override the default behavior, for example:<br><br><pre>format =&gt; json_object('recorddelimiter'<br/>VALUE ''\r\n'')</pre><br>To indicate that there is no record delimiter you can specify a <code>recorddelimiter</code> that does not occur in the input file. For example, to indicate that there is no delimiter, specify the control character 0x01 (SOH) as a value for the <code>recorddelimiter</code> and set the <code>recorddelimiter</code> value to <code>"0x'01'"</code> (this character does not occur in JSON text). For example:<br><br><pre>format =&gt; '{"recorddelimiter" :<br/>"0x'01'"}</pre> | <code>recorddelimiter: character</code><br>Default value: <code>newline</code>                                                                                                                                                                      |

| Format Option       | Description                                                                                                                                                                                                                                                                           | Syntax                                                                                                                                                                  |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rejectlimit         | The operation will error out after specified number of rows are rejected.                                                                                                                                                                                                             | rejectlimit: <i>number</i><br>Default value: 0                                                                                                                          |
| removequotes        | Removes any quotes that are around any field in the source file.                                                                                                                                                                                                                      | removequotes: true<br>Default value: False                                                                                                                              |
| skipheaders         | Specifies how many rows should be skipped from the start of the file.                                                                                                                                                                                                                 | skipheaders: <i>number</i><br>Default value: 0 if not specified, 1 if specified without a value                                                                         |
| territory           | Specifies a territory name to further determine input data characteristics.                                                                                                                                                                                                           | territory: <i>string</i><br>Default value: Null<br>See <i>Locale Data in Oracle Database Globalization Support Guide</i> for a listing of Oracle-supported territories. |
| timestampformat     | Specifies the timestamp format in the source file. The format option AUTO searches for the following formats:<br><br>YYYY-MM-DD HH:MI:SS.FF<br>YYYY-MM-DD HH:MI:SS.FF3<br>MM/DD/YYYY HH:MI:SS.FF3                                                                                     | timestampformat : <i>string</i><br>Default value: Database timestamp format<br>The string can contain wildcard characters such as "\$".                                 |
| timestamppltzformat | Specifies the timestamp with local timezone format in the source file. The format option AUTO searches for the following formats:<br><br>DD Mon YYYY HH:MI:SS.FF TZR<br>MM/DD/YYYY HH:MI:SS.FF TZR<br>YYYY-MM-DD HH:MI:SS+/-TZR<br>YYYY-MM-DD HH:MI:SS.FF3<br>DD.MM.YYYY HH:MI:SS TZR | timestamppltzformat : <i>string</i><br>Default value: Database timestamp with local timezone format                                                                     |
| timestamptzformat   | Specifies the timestamp with timezone format in the source file. The format option AUTO searches for the following formats:<br><br>DD Mon YYYY HH:MI:SS.FF TZR<br>MM/DD/YYYY HH:MI:SS.FF TZR<br>YYYY-MM-DD HH:MI:SS+/-TZR<br>YYYY-MM-DD HH:MI:SS.FF3<br>DD.MM.YYYY HH:MI:SS TZR       | timestamptzformat: <i>string</i><br>Default value: Database timestamp with timezone format                                                                              |
| trimspaces          | Specifies how the leading and trailing spaces of the fields are trimmed.<br>See the description of trim_spec.                                                                                                                                                                         | trimspaces: rtrim  ltrim  notrim <br>ltrim  ldrtrim<br>Default value: notrim                                                                                            |
| truncatecol         | If the data in the file is too long for a field, then this option will truncate the value of the field rather than reject the row.                                                                                                                                                    | truncatecol: true<br>Default value: False                                                                                                                               |
| type                | Specifies the source file type.<br>See the description of CSV in field_definitions Clause<br>See <a href="#">DBMS_CLOUD Package Format Options for Avro or Parquet</a> for type values avro or parquet.                                                                               | type: csv csv with embedded csv<br>without embedded<br>csv is the same as csv without embedded.<br>Default value: Null                                                  |

## 37.8 DBMS\_CLOUD Avro and Parquet Support

This section covers the DBMS\_CLOUD Avro and Parquet support provided with Oracle Database.

### Topics

- [DBMS\\_CLOUD Package Format Options for Avro or Parquet](#)
- [DBMS\\_CLOUD Package Avro to Oracle Data Type Mapping](#)
- [DBMS\\_CLOUD Package Parquet to Oracle Data Type Mapping](#)
- [DBMS\\_CLOUD Package Avro and Parquet Complex Types](#)
- [DBMS\\_CLOUD Package Avro and Parquet to Oracle Column Name Mapping](#)

### 37.8.1 DBMS\_CLOUD Package Format Options for Avro or Parquet

The format argument in DBMS\_CLOUD specifies the format of source files.

The two ways to specify the format argument are:

```
format => '{"format_option" : "format_value" }'
```

And:

```
format => json_object('format_option' value 'format_value')
```

Examples:

```
format => json_object('type' VALUE 'CSV')
```

To specify multiple format options, separate the values with a ",".

For example:

```
format => json_object('ignoremissingcolumns' value 'true', 'removequotes' value 'true',  
'dateformat' value 'YYYY-MM-DD-HH24-MI-SS', 'blankasnull' value 'true')
```

| Format Option | Description              | Syntax                |
|---------------|--------------------------|-----------------------|
| type          | Specifies the file type. | type : avro   parquet |

| Format Option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Syntax                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| schema        | <p>When schema is set to <code>first</code> or <code>all</code>, the external table columns and data types are automatically derived from the Avro or Parquet file metadata.</p> <p>The column names will match those found in Avro or Parquet. The data types are converted from Avro or Parquet data types to Oracle data types. All columns are added to the table.</p> <p>The value <code>first</code> specifies to use the metadata from the first Avro or Parquet file in the <code>file_uri_list</code> to auto generate the columns and their data types. Use <code>first</code> if all of the files have the same schema.</p> <p>The value <code>all</code> specifies to use the metadata from all Avro or Parquet files in the <code>file_uri_list</code> to auto generate the columns and their data types. Use <code>all</code> (slower) if the files may have different schemas.</p> <p><b>Default:</b> If <code>column_list</code> is specified, then the <code>schema</code> value, if specified is ignored. If <code>column_list</code> is not specified then the <code>schema</code> default value is <code>first</code>.</p> <p><b>Note:</b> For Avro or Parquet format files the <code>schema</code> format option is not available and the <code>column_list</code> parameter must be specified for partitioned external tables using the <code>DBMS_CLOUD.CREATE_EXTERNAL_PART_TABLE</code> procedure.</p> | <code>schema:first   all</code> |

## 37.8.2 DBMS\_CLOUD Package Avro to Oracle Data Type Mapping

Describes the mapping of Avro data types to Oracle data types.

### Note:

Complex types, such as maps, arrays, and structs are supported starting with Oracle Database 19c. See [DBMS\\_CLOUD Package Avro and Parquet Complex Types](#) for information on using Avro complex types.

| Avro Type        | Oracle Type       |
|------------------|-------------------|
| INT              | NUMBER(10)        |
| LONG             | NUMBER(19)        |
| BOOL             | NUMBER(1)         |
| UTF8 BYTE_ARRAY  | RAW(2000)         |
| FLT              | BINARY_FLOAT      |
| DBL              | BINARY_DOUBLE     |
| DECIMAL(p)       | NUMBER(p)         |
| DECIMAL(p,s)     | NUMBER(p,s)       |
| DATE             | DATE              |
| STRING           | VARCHAR2          |
| TIME_MILLIS      | VARCHAR2(20 BYTE) |
| TIME_MICROS      | VARCHAR2(20 BYTE) |
| TIMESTAMP_MILLIS | TIMESTAMP(3)      |

| Avro Type        | Oracle Type                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------|
| TIMESTAMP_MICROS | TIMESTAMP(6)                                                                                             |
| ENUM             | VARCHAR2( <i>n</i> ) Where: " <i>n</i> " is the actual maximum length of the AVRO ENUM's possible values |
| DURATION         | RAW(2000)                                                                                                |
| FIXED            | RAW(2000)                                                                                                |
| NULL             | VARCHAR2(1) BYTE                                                                                         |

See [DBMS\\_CLOUD Package Avro and Parquet Complex Types](#) for information on using Avro complex types.

### 37.8.3 DBMS\_CLOUD Package Parquet to Oracle Data Type Mapping

Describes the mapping of Parquet data types to Oracle data types.

#### Note:

Complex types, such as maps, arrays, and structs are supported starting with Oracle Database 19c. See [DBMS\\_CLOUD Package Avro and Parquet Complex Types](#) for information on using Parquet complex types.

| Parquet Type         | Oracle Type         |
|----------------------|---------------------|
| UINT_64              | NUMBER(20)          |
| INT_64               | NUMBER(19)          |
| UINT_32              | NUMBER(10)          |
| INT_32               | NUMBER(10)          |
| UINT_16              | NUMBER(5)           |
| INT_16               | NUMBER(5)           |
| UINT_8               | NUMBER(3)           |
| INT_8                | NUMBER(3)           |
| BOOL                 | NUMBER(1)           |
| UTF8 BYTE_ARRAY      | VARCHAR2(4000 BYTE) |
| FLT                  | BINARY_FLOAT        |
| DBL                  | BINARY_DOUBLE       |
| DECIMAL(p)           | NUMBER(p)           |
| DECIMAL(p,s)         | NUMBER(p,s)         |
| DATE                 | DATE                |
| STRING               | VARCHAR2(4000)      |
| TIME_MILLIS          | VARCHAR2(20 BYTE)   |
| TIME_MILLIS_UTC      | VARCHAR2(20 BYTE)   |
| TIME_MICROS          | VARCHAR2(20 BYTE)   |
| TIME_MICROS_UTC      | VARCHAR2(20 BYTE)   |
| TIMESTAMP_MILLIS     | TIMESTAMP(3)        |
| TIMESTAMP_MILLIS_UTC | TIMESTAMP(3)        |
| TIMESTAMP_MICROS     | TIMESTAMP(6)        |
| TIMESTAMP_MICROS_UTC | TIMESTAMP(6)        |

| Parquet Type    | Oracle Type  |
|-----------------|--------------|
| TIMESTAMP_NANOS | TIMESTAMP(9) |

See [DBMS\\_CLOUD Package Avro and Parquet Complex Types](#) for information on using Parquet complex types.

## 37.8.4 DBMS\_CLOUD Package Avro and Parquet Complex Types

Describes the mapping of Avro and Parquet complex data types to Oracle data types.

Oracle Database supports complex data types, including the following complex types:

- struct
- list
- map
- union
- array

When you specify a source file type of Avro or Parquet and the source file includes complex columns, Oracle Database queries return JSON for the complex columns. This simplifies processing of query results; you can use Oracle's powerful JSON parsing features consistently across the file types and data types. The following table shows the format for the complex types in Oracle Database:

### Note:

The complex fields map to VARCHAR2 columns and VARCHAR2 size limits apply.

| Type                                 | Parquet       | Avro   | Oracle                 |
|--------------------------------------|---------------|--------|------------------------|
| List: sequence of values             | List          | Array  | VARCHAR2 (JSON format) |
| Map: list of objects with single key | Map           | Map    | VARCHAR2 (JSON format) |
| Union: values of different type      | Not Available | Union  | VARCHAR2 (JSON format) |
| Object: zero or more key-value pairs | Struct        | Record | VARCHAR2 (JSON format) |

## 37.8.5 DBMS\_CLOUD Package Avro and Parquet to Oracle Column Name Mapping

Describes rules for how Avro and Parquet column names are converted to Oracle column names.

The following are supported for Avro and Parquet column names, but may require use of double quotes for Oracle SQL references in external tables. Thus, for ease of use and to avoid having to use double quotes when referencing column names, if possible do not use the following in Avro and Parquet column names:

- Embedded blanks
- Leading numbers
- Leading underscores
- Oracle SQL reserved words

The following table shows various types of Avro and Parquet column names, and rules for using the column names in Oracle column names in external tables.

| Avro or Parquet Name                                                                                                                | CREATE TABLE Name       | Oracle CATALOG      | Valid SQL                                                | Notes                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------|-------------------------|---------------------|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| part, Part, or PART                                                                                                                 | part, Part, PART        | PART                | select part<br>select Part<br>select paRt<br>select PART | Oracle implicitly uppercases unquoted column names                                                                                                     |
| Ord No                                                                                                                              | "Ord No"                | Ord No              | select "Ord No"                                          | Double quotes are required when there are embedded blanks, which also preserves the character case                                                     |
| __index_key__                                                                                                                       | "__index_key__"         | __index_key__       | select<br>"__index_key__"                                | Double quotes are required when there is a leading underscore, which also preserves the character case                                                 |
| 6Way                                                                                                                                | "6Way"                  | 6Way                | select "6Way"                                            | Double quotes are required when there is a leading numeric digit, which also preserves the character case                                              |
| create, Create, or CREATE, and so on. (any case variation) partition, Partition, PARTITION, and so on (for an Oracle Reserved word) | "CREATE"<br>"PARTITION" | CREATE<br>PARTITION | select "CREATE"<br>select<br>"PARTITION"                 | Double quotes are required around Oracle SQL Reserved words. These are forced to uppercase, but must always be double-quoted when used anywhere in SQL |

| Avro or Parquet Name                                 | CREATE TABLE Name | Oracle CATALOG | Valid SQL                                                              | Notes                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------|-------------------|----------------|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rowid, Rowid, ROWid, and so on (for ROWID see notes) | rowid             |                | <pre>select "rowid" select "Rowid" select "ROWid" select "rowid"</pre> | For ROWID, any mixed or lower-case variation of ROWID preserves the case and must always be double-quoted and use the original case variations. Due to the inherent conflict with Oracle ROWID for the table, if you specify upper-case ROWID, it is automatically stored as lower-case "rowid" and must always be double-quoted when referenced. |

 **Notes:**

- In general a column name in an external table can be referenced without double quotes.
- Unless there is an embedded blank, a leading underscore ("\_") or leading numeric digit ("0" through "9") in the column name, the original case of the column name is preserved, and it must always be referenced with double quotes and using the original case (upper, lower or mixed-case) of the Avro or Parquet column name.
- After using `DBMS_CLOUD.CREATE_EXTERNAL_TABLE` to create an external table with the format specified as `avro` or `parquet`, use the `DESCRIBE` command in `SQL*Plus` to view the table's column names.
- When Oracle SQL Reserved Words are used in Avro or Parquet column names, they must always be double-quoted when referenced anywhere in SQL. See Oracle SQL Reserved Words for more information.

# DBMS\_COMPARISON

The `DBMS_COMPARISON` package provides interfaces to compare and converge database objects at different databases.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Views](#)
- [Operational Notes](#)
- [Data Structures](#)
- [Summary of DBMS\\_COMPARISON Subprograms](#)

## 38.1 DBMS\_COMPARISON Overview

The `DBMS_COMPARISON` package is an Oracle-supplied package that you can use to compare database objects at two databases. This package also enables you converge the database objects so that they are consistent at different databases. Typically, this package is used in environments that share a database object at multiple databases. When copies of the same database object exist at multiple databases, the database object is a **shared database object**. Several data dictionary views contain information about comparisons made with the `DBMS_COMPARISON` package.

Shared database objects might be maintained by data replication. For example, materialized views or Oracle Streams components might replicate the database objects and maintain them at multiple databases. A custom application might also maintain shared database objects. When a database object is shared, it can diverge at the databases that share it. You can use this package to identify differences in the shared database objects. After identifying the differences, you can optionally use this package to synchronize the shared database objects.

To compare a database object that is shared at two different databases, complete the following general steps:

1. Run the [CREATE\\_COMPARISON Procedure](#) in this package to create a **comparison**. The comparison identifies the database objects to compare and specifies parameters for the comparison.
2. Run the [COMPARE Function](#) in this package to compare the database object at the two databases and identify differences. This function returns `TRUE` when no differences are found and `FALSE` when differences are found. This function also populates data dictionary views with comparison results. Separate comparison results are generated for each execution of the `COMPARE` function.
3. If you want to examine the comparison results, query the following data dictionary views:
  - `DBA_COMPARISON_SCAN`
  - `USER_COMPARISON_SCAN`

- DBA\_COMPARISON\_SCAN\_VALUES
  - USER\_COMPARISON\_SCAN\_VALUES
  - DBA\_COMPARISON\_ROW\_DIF
  - USER\_COMPARISON\_ROW\_DIF
4. If there are differences, and you want to synchronize the database objects at the two databases, then run the `CONVERGE` procedure in this package.

After you create a comparison with the `CREATE_COMPARISON` procedure in the `DBMS_COMPARISON` package, you can run the comparison at any time using the `COMPARE` function. Each time you run the `COMPARE` function, it records comparison results in the appropriate data dictionary views. Comparison results might be modified when subprograms in this package are invoked and the scans in the comparison results are specified. For example, comparison results might be modified when you run the `RECHECK` function.

The comparison results for a single execution of the `COMPARE` function can include one or more **scans**. A scan checks for differences in some or all of the rows in a shared database object at a single point in time. You can compare database objects multiple times, and a unique scan ID identifies each scan in the comparison results.

A **bucket** is a range of rows in a database object that is being compared. Buckets improve performance by splitting the database object into ranges and comparing the ranges independently. Every comparison divides the rows being compared into an appropriate number of buckets, and each bucket is compared by a scan.

Each time the `COMPARE` function splits a bucket into smaller buckets, it performs new scans of the smaller buckets. The scan that analyzes a larger bucket is the **parent scan** of each scan that analyzes the smaller buckets into which the larger bucket was split. The **root scan** in the comparison results is the highest level parent scan. The root scan does not have a parent.

You can recheck a scan using the `RECHECK` function, and you can converge a scan using the `CONVERGE` procedure. When you want to recheck or converge all of the rows comparison results, specify the root scan ID for the comparison results in the appropriate subprogram. When you want to recheck or converge a portion of the rows in comparison results, specify the scan ID of the scan that contains the differences.

## 38.2 DBMS\_COMPARISON Security Model

Security on this package can be controlled in one of two ways.

- Granting `EXECUTE` on this package to selected users or roles.
- Granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

Each subprogram in the `DBMS_COMPARISON` package has a `comparison_name` parameter. The current user must be the owner of the specified comparison to run a subprogram in the `DBMS_COMPARISON` package.

To run the `COMPARE` function, `RECHECK` function, or `CONVERGE` procedure, the following users must have the `SELECT` or `READ` privilege on each copy of the shared database object:

- The comparison owner at the local database

- When a database link is used, the user at the remote database to which the comparison owner connects through a database link

The `CONVERGE` procedure also requires additional privileges for one of these users at the database where it makes changes to the shared database object. The user must have `INSERT`, `UPDATE`, and `DELETE` privileges on the shared database object at this database.

In addition, when the `CONVERGE` procedure is run with either the `local_converge_tag` or `remote_converge_tag` parameter set to a non-NULL value, then the following additional requirements must be met:

- If the local table "wins," then the user at the remote database to which the invoker of the `CONVERGE` procedure connects through a database link must be granted either `EXECUTE_CATALOG_ROLE` or `EXECUTE` privilege on the `DBMS_STREAMS_ADM` package.
- If the remote table "wins," then the invoker of the `CONVERGE` procedure at the local database must be granted either `EXECUTE_CATALOG_ROLE` or `EXECUTE` privilege on the `DBMS_STREAMS_ADM` package.

**Note:**

The database administrator (DBA) can assume control over some of the `DBMS_COMPARISON` functions and procedures owned by other users. This control applies to `DROP_COMPARISON` and `PURGE_COMPARISON`. This DBA override can be particularly useful in cleanup operations when comparisons created by another user need to be dropped

### 38.3 DBMS\_COMPARISON Constants

The `DBMS_COMPARISON` package defines several enumerated constants to use specifying parameter values. Enumerated constants must be prefixed with the package name. For example, `DBMS_COMPARISON.CMP_SCAN_MODE_FULL`.

Table 38-1 lists the parameters and enumerated constants.

**Table 38-1 DBMS\_COMPARISON Parameters with Enumerated Constants**

| Parameter                    | Option                                                                                 | Type                      | Description                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>comparison_mode</code> | <ul style="list-style-type: none"><li>• <code>CMP_COMPARE_MODE_OBJECT</code></li></ul> | <code>VARCHAR2(30)</code> | <code>CMP_COMPARE_MODE_OBJECT</code> is a database object. This constant can be specified as <code>'OBJECT'</code> . |

**Table 38-1 (Cont.) DBMS\_COMPARISON Parameters with Enumerated Constants**

| Parameter          | Option                                                                                                                                                         | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scan_mode          | <ul style="list-style-type: none"> <li>CMP_SCAN_MODE_FULL</li> <li>CMP_SCAN_MODE_RANDOM</li> <li>CMP_SCAN_MODE_CYCLIC</li> <li>CMP_SCAN_MODE_CUSTOM</li> </ul> | VARCHAR2 (30)  | <p>CMP_SCAN_MODE_FULL indicates that the entire database object is compared. This constant can be specified as 'FULL'.</p> <p>CMP_SCAN_MODE_RANDOM indicates that a random portion of the database object is compared. This constant can be specified as 'RANDOM'.</p> <p>CMP_SCAN_MODE_CYCLIC indicates that a portion of the database object is compared when you perform a single comparison. When you compare the database object again, another portion of the database object is compared, starting where the last comparison ended. This constant can be specified as 'CYCLIC'.</p> <p>CMP_SCAN_MODE_CUSTOM indicates that the user who runs the subprogram specifies the range to compare in the database object. This constant can be specified as 'CUSTOM'.</p> |
| converge_options   | <ul style="list-style-type: none"> <li>CMP_CONVERGE_LOCAL_WINS</li> <li>CMP_CONVERGE_REMOTE_WINS</li> </ul>                                                    | VARCHAR2 (30)  | <p>CMP_CONVERGE_LOCAL_WINS indicates that the column values at the local database replace the column values at the remote database when these column values are different. This constant can be specified as 'LOCAL'.</p> <p>CMP_CONVERGE_REMOTE_WINS indicates that the column values at the remote database replace the column values at the local database when these column values are different. This constant can be specified as 'REMOTE'.</p>                                                                                                                                                                                                                                                                                                                     |
| null_value         | <ul style="list-style-type: none"> <li>CMP_NULL_VALUE_DEF</li> </ul>                                                                                           | VARCHAR2 (100) | CMP_NULL_VALUE_DEF indicates that ORA\$STREAMS\$NV is substituted for NULL values in database objects during comparison. This constant can be specified as 'ORA\$STREAMS\$NV'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| max_num_buckets    | <ul style="list-style-type: none"> <li>CMP_MAX_NUM_BUCKETS</li> </ul>                                                                                          | INTEGER        | CMP_MAX_NUM_BUCKETS indicates that the maximum number of buckets is 1,000. This constant can be specified as 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| min_rows_in_bucket | <ul style="list-style-type: none"> <li>CMP_MIN_ROWS_IN_BUCKET</li> </ul>                                                                                       | INTEGER        | CMP_MIN_ROWS_IN_BUCKET indicates that the minimum number of rows in a bucket is 10,000. This constant can be specified as 10000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 38.4 DBMS\_COMPARISON Views

The `DBMS_COMPARISON` package uses several views.

These views are listed below:

- `DBA_COMPARISON`
- `USER_COMPARISON`
- `DBA_COMPARISON_COLUMNS`
- `USER_COMPARISON_COLUMNS`
- `DBA_COMPARISON_SCAN`
- `USER_COMPARISON_SCAN`
- `DBA_COMPARISON_SCAN_VALUES`
- `USER_COMPARISON_SCAN_VALUES`
- `DBA_COMPARISON_ROW_DIF`
- `USER_COMPARISON_ROW_DIF`

### See Also:

*Oracle Database Reference*

## 38.5 DBMS\_COMPARISON Operational Notes

The `DBMS_COMPARISON` package has certain requirements and operational notes.

These include the following:

- Oracle Database Release Requirements for the `DBMS_COMPARISON` Package
- Database Character Set Requirements for the `DBMS_COMPARISON` Package
- Database Object Requirements for the `DBMS_COMPARISON` Package
- Index Column Requirements for the `DBMS_COMPARISON` Package
- Datatype Requirements for the `DBMS_COMPARISON` Package
- Only Converge Rows That Are Not Being Updated

### Oracle Database Release Requirements for the `DBMS_COMPARISON` Package

Meet the following Oracle Database release requirements when running the subprograms in the `DBMS_COMPARISON` package:

- The local database that runs the subprograms in the `DBMS_COMPARISON` package must be an Oracle Database 11g Release 1 (11.1) database.
- The remote database must be an Oracle Database 10g Release 1 (10.1) or later database. Oracle databases before this release and non-Oracle databases are not supported.

### Database Character Set Requirements for the DBMS\_COMPARISON Package

The database character sets must be the same for the databases that contain the database objects being compared.

#### See Also:

*Oracle Database Globalization Support Guide* for information about database character sets

### Database Object Requirements for the DBMS\_COMPARISON Package

The DBMS\_COMPARISON package can compare the following types of database objects:

- Tables
- Single-table views
- Materialized views
- Synonyms for tables, single-table views, and materialized views

Database objects of different types can be compared and converged at different databases. For example, a table at one database and a materialized view at another database can be compared and converged with this package.

To run the subprograms in the DBMS\_COMPARISON package, the specified database objects must have the same shape at each database. Specifically, the database objects must have the same number of columns at each database, and the datatypes of corresponding columns must match.

If a database object being compared contains columns that do not exist in the other database object, then you can compare the database objects by excluding the extra columns during comparison creation. Use the `column_list` parameter in the `CREATE_COMPARISON` procedure to list only the columns that exist in both database objects.

#### See Also:

[CREATE\\_COMPARISON Procedure](#)

### Index Column Requirements for the DBMS\_COMPARISON Package

This section discusses number, timestamp, and interval columns. These include the following datatypes:

- Number columns are of the following datatypes: NUMBER, FLOAT, BINARY\_FLOAT, and BINARY\_DOUBLE.
- Timestamp columns are of the following datatypes: TIMESTAMP, TIMESTAMP WITH TIME ZONE, and TIMESTAMP WITH LOCAL TIME ZONE
- Interval columns are of the following datatypes: INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND.

For all scan modes to be supported by the `DBMS_COMPARISON` package, the database objects must have one of the following types of indexes:

- A single-column index on a number, timestamp, interval, or `DATE` datatype column
- A composite index that only includes number, timestamp, interval, or `DATE` datatype columns. Each column in the composite index must either have a `NOT NULL` constraint or be part of the primary key.

For the scan modes `CMP_SCAN_MODE_FULL` and `CMP_SCAN_MODE_CUSTOM` to be supported, the database objects must have one of the following types of indexes:

- A single-column index on a number, timestamp, interval, `DATE`, `VARCHAR2`, or `CHAR` datatype column
- A composite index that only includes number, timestamp, interval, `DATE`, `VARCHAR2`, or `CHAR` columns. Each column in the composite index must either have a `NOT NULL` constraint or be part of the primary key.

If the database objects do not have one of these types of indexes, then the `DBMS_COMPARISON` package does not support the database objects. For example, if the database objects only have a single index on an `NVARCHAR2` column, then the `DBMS_COMPARISON` package does not support them. Or, if the database objects have only one index, and it is a composite index that includes a `NUMBER` column and an `NCHAR` column, then the `DBMS_COMPARISON` package does not support them.

You can specify an index when you create a comparison using the `index_schema_name` and `index_name` parameters in the `CREATE_COMPARISON` procedure. If you specify an index, then make sure the columns in the index meet the requirements of the scan mode used for the comparison.

The index columns in a comparison must uniquely identify every row involved in a comparison. The following constraints satisfy this requirement:

- A primary key constraint
- A unique constraint on one or more non-`NULL` columns

If these constraints are not present on a table, then use the `index_schema_name` and `index_name` parameters in the `CREATE_COMPARISON` procedure to specify an index whose columns satisfy this requirement.

When a single index value identifies both a local row and a remote row, the two rows must be copies of the same row in the replicated tables. In addition, each pair of copies of the same row must always have the same index value.

The `DBMS_COMPARISON` package can use an index only if all of the columns in the index are included in the `column_list` parameter when the comparison is created with the `CREATE_COMPARISON` procedure.

After a comparison is created, you can determine the index column or columns for it by running the following query:

```
SELECT COLUMN_NAME, COLUMN_POSITION FROM DBA_COMPARISON_COLUMNS
WHERE COMPARISON_NAME = 'COMPARE_CUSTOM' AND
      INDEX_COLUMN      = 'Y';
```

If there are multiple index columns, then the index column with 1 for the `COLUMN_POSITION` is the lead index column in the composite index.

**See Also:**

- ["Constants"](#) for information about scan modes
- [CREATE\\_COMPARISON Procedure](#) for information about specifying an index for a comparison

**Datatype Requirements for the DBMS\_COMPARISON Package**

The DBMS\_COMPARISON package can compare data in columns of the following datatypes:

- VARCHAR2
- NVARCHAR2
- NUMBER
- FLOAT
- DATE
- BINARY\_FLOAT
- BINARY\_DOUBLE
- TIMESTAMP
- TIMESTAMP WITH TIME ZONE
- TIMESTAMP WITH LOCAL TIME ZONE
- INTERVAL YEAR TO MONTH
- INTERVAL DAY TO SECOND
- RAW
- CHAR
- NCHAR

If a column with datatype `TIMESTAMP WITH LOCAL TIME ZONE` is compared, then the two databases must use the same time zone. Also, if a column with datatype `NVARCHAR2` or `NCHAR` is compared, then the two databases must use the same national character set.

The DBMS\_COMPARISON package cannot compare data in columns of the following datatypes:

- LONG
- LONG RAW
- ROWID
- UROWID
- CLOB
- NCLOB
- BLOB
- BFILE
- User-defined types (including object types, `REFs`, varrays, and nested tables)

- Oracle-supplied types (including any types, XML types, spatial types, and media types)

You can compare database objects that contain unsupported columns by excluding the unsupported columns during comparison creation. Use the `column_list` parameter in the `CREATE_COMPARISON` procedure to list only the supported columns in a shared database object.

 **See Also:**

- [CREATE\\_COMPARISON Procedure](#)
- *Oracle Database SQL Language Reference* for more information about datatypes
- *Oracle Database Globalization Support Guide* for information about national character sets

### Only Converge Rows That Are Not Being Updated

You should only converge rows that are not being updated on either database. For example, if the shared database object is updated by replication components, then only converge rows for which replication changes have been applied and make sure no new changes are in the process of being replicated for these rows. If you compare replicated database objects, then it is typically best to compare them during a time of little or no replication activity to identify persistent differences.

 **Note:**

If a scan identifies that a row is different in the shared database object at two databases, and the row is modified after the scan, then it can result in unexpected data in the row after the `CONVERGE` procedure is run.

## 38.6 DBMS\_COMPARISON Data Structures

The `DBMS_COMPARISON` package defines a `RECORD` type.

Contains information returned by the `COMPARE` function or `CONVERGE` procedure in the `DBMS_COMPARISON` package.

 **Note:**

The `COMPARE` function only returns a value for the `scan_id` field.

## 38.6.1 COMPARISON\_TYPE Record Type

This record type contains information returned by the `COMPARE` function or `CONVERGE` procedure in the `DBMS_COMPARISON` package.

**Note:**

The `COMPARE` function only returns a value for the `scan_id` field.

**Syntax**

```
TYPE COMPARISON_TYPE IS RECORD(  
    scan_id          NUMBER,  
    loc_rows_merged  NUMBER,  
    rmt_rows_merged  NUMBER,  
    loc_rows_deleted NUMBER,  
    rmt_rows_deleted NUMBER);
```

**Table 38-2** COMPARISON\_TYPE Attributes

| Field                         | Description                                                                                                                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>scan_id</code>          | The scan ID of the scan                                                                                                          |
| <code>loc_rows_merged</code>  | The number of rows in the local database object updated with information from the database object at the remote site             |
| <code>rmt_rows_merged</code>  | The number of rows in the database object updated at the remote site with information from the database object at the local site |
| <code>loc_rows_deleted</code> | The number of rows deleted from the local database object                                                                        |
| <code>rmt_rows_deleted</code> | The number of rows deleted from the remote database object                                                                       |

## 38.7 Summary of DBMS\_COMPARISON Subprograms

This table lists the `DBMS_COMPARISON` subprograms and briefly describes them.

**Table 38-3** DBMS\_COMPARISON Package Subprograms

| Subprogram                                  | Description                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">COMPARE Function</a>            | Performs the specified comparison                                                                                                           |
| <a href="#">CONVERGE Procedure</a>          | Executes data manipulation language (DML) changes to synchronize the portion of the database object that was compared in the specified scan |
| <a href="#">CREATE_COMPARISON Procedure</a> | Creates a comparison                                                                                                                        |
| <a href="#">DROP_COMPARISON Procedure</a>   | Drops a comparison                                                                                                                          |
| <a href="#">PURGE_COMPARISON Procedure</a>  | Purges the comparison results, or a subset of the comparison results, for a comparison                                                      |
| <a href="#">RECHECK Function</a>            | Rechecks the differences in a specified scan for a comparison                                                                               |

## 38.7.1 COMPARE Function

This function performs the specified comparison.

Each time a comparison is performed, it results in at least one new scan, and each scan has a unique scan ID. You can define and name a comparison using the `CREATE_COMPARISON` procedure.

### See Also:

- ["Overview"](#)
- [CREATE\\_COMPARISON Procedure](#)

### Syntax

```
DBMS_COMPARISON.COMPARE (
    comparison_name IN   VARCHAR2,
    scan_info       OUT  COMPARISON_TYPE,
    min_value       IN   VARCHAR2  DEFAULT NULL,
    max_value       IN   VARCHAR2  DEFAULT NULL,
    perform_row_dif IN   BOOLEAN   DEFAULT FALSE)
RETURN BOOLEAN;
```

### Parameters

**Table 38-4 COMPARE Function Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comparison_name</code> | The name of the comparison.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>scan_info</code>       | Information about the compare operation returned in the <code>COMPARISON_TYPE</code> datatype.<br>See <a href="#">COMPARISON_TYPE Record Type</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>min_value</code>       | When the scan mode for the comparison is set to <code>CMP_SCAN_MODE_CUSTOM</code> , specify the minimum index column value for the range of rows that are being compared. To determine the index column for a comparison, query the <code>DBA_COMPARISON_COLUMNS</code> data dictionary view. For a composite index, specify a value for the column with <code>column_position</code> equal to 1 in the <code>DBA_COMPARISON_COLUMNS</code> view. See the index column requirements under <a href="#">DBMS_COMPARISON Operational Notes</a> .<br>If the scan mode is set to a value other than <code>CMP_SCAN_MODE_CUSTOM</code> , then this parameter must be set to <code>NULL</code> .<br>If <code>NULL</code> and the <code>scan_mode</code> parameter is set to <code>CMP_SCAN_MODE_CUSTOM</code> , then an error is raised.<br>To determine the scan mode for the comparison, query the <code>DBA_COMPARISON</code> data dictionary view.<br>See <a href="#">DBMS_COMPARISON Constants</a> for information about scan modes. |

**Table 38-4 (Cont.) COMPARE Function Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max_value       | <p>When the scan mode for the comparison is set to <code>CMP_SCAN_MODE_CUSTOM</code>, specify the maximum index column value for the range of rows that are being compared. To determine the index column for a comparison, query the <code>DBA_COMPARISON_COLUMNS</code> data dictionary view. For a composite index, specify a value for the column with <code>column_position</code> equal to 1 in the <code>DBA_COMPARISON_COLUMNS</code> view. See the index column requirements under <a href="#">DBMS_COMPARISON Operational Notes</a>.</p> <p>If the scan mode is set to a value other than <code>CMP_SCAN_MODE_CUSTOM</code>, then this parameter must be set to <code>NULL</code>.</p> <p>If <code>NULL</code> and the <code>scan_mode</code> parameter is set to <code>CMP_SCAN_MODE_CUSTOM</code>, then an error is raised.</p> <p>To determine the scan mode for the comparison, query the <code>DBA_COMPARISON</code> data dictionary view.</p> <p>See <a href="#">DBMS_COMPARISON Constants</a> for information about scan modes.</p> |
| perform_row_dif | <p>If <code>TRUE</code>, then compares each row individually in the database object being compared after reaching the smallest possible bucket for the comparison.</p> <p>If <code>FALSE</code>, then compares buckets for differences but does not compare each row individually when differences are found in the smallest possible bucket.</p> <p>See <a href="#">DBMS_COMPARISON Overview</a> for information about buckets.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Return Values

This function returns `TRUE` when no differences are found in the database objects being compared. This function returns `FALSE` when differences are found in the database objects being compared.

## 38.7.2 CONVERGE Procedure

This procedure executes data manipulation language (DML) changes to synchronize the portion of the database objects that was compared in the specified scan.

### Syntax

```
DBMS_COMPARISON.CONVERGE(
    comparison_name    IN    VARCHAR2,
    scan_id            IN    NUMBER,
    scan_info          OUT   COMPARISON_TYPE,
    converge_options    IN    VARCHAR2  DEFAULT CMP_CONVERGE_LOCAL_WINS,
    perform_commit      IN    BOOLEAN   DEFAULT TRUE,
    local_converge_tag  IN    RAW        DEFAULT NULL,
    remote_converge_tag IN    RAW        DEFAULT NULL);
```

### Parameters

**Table 38-5 CONVERGE Procedure Parameters**

| Parameter       | Description                 |
|-----------------|-----------------------------|
| comparison_name | The name of the comparison. |

**Table 38-5 (Cont.) CONVERGE Procedure Parameters**

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scan_id             | The identifier for the scan that contains the differences between the database objects being converged.<br>See <a href="#">"Overview"</a> for more information about specifying a scan ID in this parameter.                                                                                                                                                                                                                                                                                                                                                                |
| scan_info           | Information about the converge operation returned in the <code>COMPARISON_TYPE</code> datatype.<br>See <a href="#">COMPARISON_TYPE Record Type</a> .                                                                                                                                                                                                                                                                                                                                                                                                                        |
| converge_options    | Either the <code>CMP_CONVERGE_LOCAL_WINS</code> constant or the <code>CMP_CONVERGE_REMOTE_WINS</code> constant.<br>See <a href="#">"Constants"</a> for information about these constants.                                                                                                                                                                                                                                                                                                                                                                                   |
| perform_commit      | If <code>TRUE</code> , then performs a <code>COMMIT</code> periodically while making the DML changes. The <code>CONVERGE</code> procedure might perform more than one <code>COMMIT</code> when this parameter is set to <code>TRUE</code> .<br>If <code>FALSE</code> , then does not perform a <code>COMMIT</code> after making DML changes.                                                                                                                                                                                                                                |
| local_converge_tag  | The Replication tag to set in the session on the local database before performing any changes to converge the data in the database objects being converged.<br>If non- <code>NULL</code> , then this parameter setting takes precedence over the <code>local_converge_tag</code> parameter in the <code>CREATE_COMPARISON</code> procedure that created the comparison.<br>If <code>NULL</code> , then this parameter is ignored, and the <code>local_converge_tag</code> parameter in the <code>CREATE_COMPARISON</code> procedure that created the comparison is used.    |
| remote_converge_tag | The Replication tag to set in the session on the remote database before performing any changes to converge the data in the database objects being converged.<br>If non- <code>NULL</code> , then this parameter setting takes precedence over the <code>remote_converge_tag</code> parameter in the <code>CREATE_COMPARISON</code> procedure that created the comparison.<br>If <code>NULL</code> , then this parameter is ignored, and the <code>remote_converge_tag</code> parameter in the <code>CREATE_COMPARISON</code> procedure that created the comparison is used. |

#### Usage Notes

If one of the database objects being converged is a read-only materialized view, then the `converge_options` parameter must be set to ensure that the read-only materialized view "wins" in the converge operation. The `CONVERGE` procedure raises an error if it tries to make changes to a read-only materialized view.

## 38.7.3 CREATE\_COMPARISON Procedure

This procedure creates a comparison.

#### Syntax

```
DBMS_COMPARISON.CREATE_COMPARISON(
    comparison_name    IN  VARCHAR2,
    schema_name        IN  VARCHAR2,
```

```

object_name          IN  VARCHAR2,
dblink_name          IN  VARCHAR2,
index_schema_name    IN  VARCHAR2  DEFAULT NULL,
index_name           IN  VARCHAR2  DEFAULT NULL,
remote_schema_name    IN  VARCHAR2  DEFAULT NULL,
remote_object_name    IN  VARCHAR2  DEFAULT NULL,
comparison_mode       IN  VARCHAR2  DEFAULT CMP_COMPARE_MODE_OBJECT,
column_list           IN  VARCHAR2  DEFAULT '*',
scan_mode             IN  VARCHAR2  DEFAULT CMP_SCAN_MODE_FULL,
scan_percent          IN  NUMBER     DEFAULT NULL,
null_value            IN  VARCHAR2  DEFAULT CMP_NULL_VALUE_DEF,
local_converge_tag    IN  RAW        DEFAULT NULL,
remote_converge_tag   IN  RAW        DEFAULT NULL,
max_num_buckets       IN  NUMBER     DEFAULT CMP_MAX_NUM_BUCKETS,
min_rows_in_bucket    IN  NUMBER     DEFAULT CMP_MIN_ROWS_IN_BUCKET);

```

## Parameters

**Table 38-6 CREATE\_COMPARISON Procedure Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| comparison_name    | The name of the comparison.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| schema_name        | The name of the schema that contains the local database object to compare.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| object_name        | The name of the local database object to compare.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| dblink_name        | Database link to the remote database. The specified database object in the remote database is compared with the database object in the local database.<br><br>If NULL, then the comparison is configured to compare two database objects in the local database. In this case, parameters that specify the remote database object apply to the second database object in the comparison and to operations on the second database object. For example, specify the second database object in this procedure by using the remote_schema_name and remote_object_name parameters. |
| index_schema_name  | The name of the schema that contains the index.<br><br>If NULL, then the schema specified in the schema_name parameter is used.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| index_name         | The name of the index.<br><br>If NULL, then the system determines the index columns for the comparison automatically.<br><br>If the index_schema_name parameter is non-NULL, then the index_name parameter must also be non-NULL. Otherwise, an error is raised.<br><br><b>See Also:</b> "Usage Notes" for more information about specifying an index                                                                                                                                                                                                                        |
| remote_schema_name | The name of the schema that contains the database object at the remote database. Specify a non-NULL value if the schema names are different at the two databases.<br><br>If NULL, then the schema specified in the schema_name parameter is used.                                                                                                                                                                                                                                                                                                                            |

**Table 38-6 (Cont.) CREATE\_COMPARISON Procedure Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| remote_object_name | <p>The name of the database object at the remote database. Specify a non-NULL value if the database object names are different at the two databases.</p> <p>If NULL, then the database object specified in the object_name parameter is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| comparison_mode    | <p>Specify the default value CMP_COMPARE_MODE_OBJECT. Additional modes might be added in future releases.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| column_list        | <p>Specify '*' to include all of the columns in the database objects being compared.</p> <p>To compare a subset of columns in the database objects, specify a comma-delimited list of the columns to check. Any columns that are not in the list are ignored during a comparison and convergence.</p> <p>See <a href="#">"Usage Notes"</a> for information about columns that are required in the column_list parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| scan_mode          | <p>Either CMP_SCAN_MODE_FULL, CMP_SCAN_MODE_RANDOM, CMP_SCAN_MODE_CYCLIC, or CMP_SCAN_MODE_CUSTOM.</p> <p>If you specify CMP_SCAN_MODE_CUSTOM, then make sure you specify an index using the index_schema_name and index_name parameters. Specifying an index ensures that you can specify the correct min_value and max_value for the lead index column when you run the COMPARE or RECHECK function.</p> <p>See <a href="#">"Constants"</a> for information about these constants.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| scan_percent       | <p>The percentage of the database object to scan for comparison when the scan_mode parameter is set to either CMP_SCAN_MODE_RANDOM or CMP_SCAN_MODE_CYCLIC. For these scan_mode settings, a non-NULL value that is greater than 0 (zero) and less than 100 is required.</p> <p>If NULL and the scan_mode parameter is set to CMP_SCAN_MODE_FULL, then the entire database object is scanned for comparison.</p> <p>If NULL and the scan_mode parameter is set to CMP_SCAN_MODE_CUSTOM, then the portion of the database object scanned for comparison is specified when the COMPARE function is run.</p> <p>If non-NULL and the scan_mode parameter is set to either CMP_SCAN_MODE_FULL or CMP_SCAN_MODE_CUSTOM, then the scan_percent parameter is ignored.</p> <p><b>Note:</b> When the scan_percent parameter is non-NULL, and the lead index column for the comparison does not distribute the rows in the database object evenly, the portion of the database object that is compared might be smaller or larger than the specified scan_percent value. See <a href="#">DBMS_COMPARISON Operational Notes</a> for more information about the DBMS_COMPARISON package index requirements for the lead index column.</p> |
| null_value         | <p>The value to substitute for each NULL in the database objects being compared. Specify a value or use the CMP_NULL_VALUE_DEF constant.</p> <p>If a column being compared can contain NULLs, then the value specified for this parameter must be different than any non-NULL value in the column. Otherwise, if the value specified for this parameter can appear in the column, some row differences might not be found.</p> <p>See <a href="#">"Constants"</a> for information about this constant.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 38-6 (Cont.) CREATE\_COMPARISON Procedure Parameters**

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local_converge_tag  | <p>The Oracle Replication tag to set in the session on the local database before performing any changes to converge the data in the database objects being compared.</p> <p>If the local_converge_tag parameter is non-NULL in the CONVERGE procedure when comparison results for this comparison are converged, then the setting in the CONVERGE procedure takes precedence. See <a href="#">CONVERGE Procedure</a> for more information.</p>   |
| remote_converge_tag | <p>The Oracle Replication tag to set in the session on the remote database before performing any changes to converge the data in the database objects being compared.</p> <p>If the remote_converge_tag parameter is non-NULL in the CONVERGE procedure when comparison results for this comparison are converged, then the setting in the CONVERGE procedure takes precedence. See <a href="#">CONVERGE Procedure</a> for more information.</p> |
| max_num_buckets     | <p>Specify the maximum number of buckets to use. Specify a value or use the CMP_MAX_NUM_BUCKETS constant. See "<a href="#">Constants</a>" for information about this constant.</p> <p>See "<a href="#">Overview</a>" for information about buckets.</p> <p><b>Note:</b> If an index column for a comparison is a VARCHAR2 or CHAR column, then the number of buckets might exceed the value specified for the max_num_buckets parameter.</p>     |
| min_rows_in_bucket  | <p>Specify the minimum number of rows in each bucket. Specify a value or use the CMP_MIN_ROWS_IN_BUCKET constant. See "<a href="#">Constants</a>" for information about this constant.</p> <p>See "<a href="#">Overview</a>" for information about buckets.</p>                                                                                                                                                                                  |

### Usage Notes

This section contains usage notes for the CREATE\_COMPARISON procedure.

#### Usage Notes for the index\_schema\_name and index\_name Parameters

When you specify an index for a comparison with the index\_schema\_name and index\_name parameters, the specified index determines the comparison's index columns and their ordering. The order of the columns in the index determines the index column ordering for the comparison. Therefore, the column in column position 1 in the index is the lead column for the comparison.

The index columns and their ordering affect the details of each SQL statement generated and executed for a comparison. For each SQL statement, the optimizer decides whether to use indexes. If the optimizer decides to use indexes, then the optimizer decides which particular indexes to use. An index specified in column\_list parameter might or might not be used.

The columns in the specified index must meet the requirements described in [DBMS\\_COMPARISON Operational Notes](#). If the index columns do not meet these requirements, then an error is raised.

#### Note:

If you do not specify an index when you create a comparison, then the `CREATE_COMPARISON` procedure selects either the primary key, if it exists, or an existing unique index. The procedure never selects a non-unique index. However, if you specify an index, then the `CREATE_COMPARISON` procedure does not check its uniqueness. Therefore, if you specify a non-unique index, and duplicate index keys exist, then the results might be incorrect when the `CONVERGE` procedure synchronizes data.

#### Usage Notes for the `column_list` Parameter

When the `column_list` parameter is set to a value other than `'*'`, the following columns are required in the `column_list` parameter:

- Any columns that are required to meet the index column requirements for the `DBMS_COMPARISON` package. If the `index_name` parameter is non-NULL, then the columns in the specified index must be in the column list. If the `index_name` parameter is NULL, then see [DBMS\\_COMPARISON Operational Notes](#) for information about the `DBMS_COMPARISON` index requirements.
- If you plan to use the `CONVERGE` procedure to make changes to a database object based on the comparison, then any columns in this database object that have a `NOT NULL` constraint but no default value must be included in the column list. If these columns are not included, then the `CONVERGE` procedure returns an error. See [CONVERGE Procedure](#).

## 38.7.4 DROP\_COMPARISON Procedure

This procedure drops a comparison.

#### Syntax

```
DBMS_COMPARISON.DROP_COMPARISON(
    comparison_name IN VARCHAR2);
```

#### Parameters

**Table 38-7 DROP\_COMPARISON Procedure Parameters**

| Parameter                    | Description                 |
|------------------------------|-----------------------------|
| <code>comparison_name</code> | The name of the comparison. |

## 38.7.5 PURGE\_COMPARISON Procedure

This procedure purges the comparison results, or a subset of the comparison results, for a comparison.

### Note:

At least one of the following parameters must be set to `NULL`: `scan_id` or `purge_time`. If both the `scan_id` and `purge_time` parameters are `NULL`, then this procedure purges all comparison results for the comparison.

### Syntax

```
DBMS_COMPARISON.PURGE_COMPARISON (
    comparison_name IN VARCHAR2,
    scan_id         IN NUMBER    DEFAULT NULL,
    purge_time      IN TIMESTAMP DEFAULT NULL);
```

### Parameters

**Table 38-8 PURGE\_COMPARISON Procedure Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comparison_name</code> | The name of the comparison.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>scan_id</code>         | <p>The scan ID of the scan for which results are purged. The scan ID must identify a root scan. If the scan ID does not identify a root scan, then an error is raised. When a root scan ID is specified, it is purged, and all direct and indirect child scans of the specified root scan are purged.</p> <p>If <code>NULL</code>, then no scan ID is considered when purging comparison results for the comparison.</p> <p>See "<a href="#">Overview</a>" for information about scans.</p> |
| <code>purge_time</code>      | <p>The date before which results are purged.</p> <p>If <code>NULL</code>, then no date is considered when purging comparison results for the comparison.</p>                                                                                                                                                                                                                                                                                                                                |

## 38.7.6 RECHECK Function

This function rechecks the differences in a specified scan for a comparison.

This function performs one of the following actions:

- If the specified scan completed successfully the last time it ran, then this function checks the previously identified differences in the scan.
- If the specified scan completed partially, then this function continues to check the database object from the point where the previous scan ended.

#### Note:

This function does not compare the shared database object for differences that were not recorded in the specified comparison scan. To check for those differences, run the `COMPARE` function.

#### See Also:

[COMPARE Function](#)

### Syntax

```
DBMS_COMPARISON.RECHECK(
    comparison_name IN VARCHAR2,
    scan_id         IN NUMBER,
    perform_row_dif IN BOOLEAN DEFAULT FALSE)
RETURN BOOLEAN;
```

### Parameters

**Table 38-9 RECHECK Function Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comparison_name</code> | The name of the comparison.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>scan_id</code>         | The scan ID of the scan to recheck.<br>See " <a href="#">Overview</a> " for more information about specifying a scan ID in this parameter.                                                                                                                                                                                                                                                                   |
| <code>perform_row_dif</code> | If <code>TRUE</code> , then compares each row individually in the database objects being compared after reaching the smallest possible bucket for the comparison.<br>If <code>FALSE</code> , then compares buckets for differences but does not compare each row individually when differences are found in the smallest possible bucket.<br>See " <a href="#">Overview</a> " for information about buckets. |

### Return Values

This function returns `TRUE` when no differences are found in the database objects being compared. This function returns `FALSE` when differences are found in the database objects being compared.

# DBMS\_COMPRESSION

The `DBMS_COMPRESSION` package provides an interface to facilitate choosing the correct compression level for an application.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Data Structures](#)
- [Summary of DBMS\\_COMPRESSION Subprograms](#)

## See Also:

- *Oracle Database Reference*

## 39.1 DBMS\_COMPRESSION Overview

The `DBMS_COMPRESSION` package gathers compression-related information within a database environment. This includes tools for estimating compressibility of a table for both partitioned and non-partitioned tables, and gathering row-level compression information on previously compressed tables. This gives the user with adequate information to make compression-related decision.

## 39.2 DBMS\_COMPRESSION Security Model

The `DBMS_COMPRESSION` package is defined with `AUTHID CURRENT USER`, so it executes with the privileges of the current user.

## 39.3 DBMS\_COMPRESSION Constants

The `DBMS_COMPRESSION` package uses constants that can be used for specifying parameter values.

These constants are shown in the following table:

**Table 39-1 DBMS\_COMPRESSION Constants - Compression Types**

| Constant                    | Type   | Value   | Description                                                                                      |
|-----------------------------|--------|---------|--------------------------------------------------------------------------------------------------|
| COMP_NOCOMPRESS             | NUMBER | 1       | No compression                                                                                   |
| COMP_ADVANCED               | NUMBER | 2       | Advanced row compression                                                                         |
| COMP_QUERY_HIGH             | NUMBER | 4       | High for query warehouse compression (Hybrid Columnar Compression)                               |
| COMP_QUERY_LOW              | NUMBER | 8       | Low for query warehouse compression (Hybrid Columnar Compression)                                |
| COMP_ARCHIVE_HIGH           | NUMBER | 16      | High archive compression (Hybrid Columnar Compression)                                           |
| COMP_ARCHIVE_LOW            | NUMBER | 32      | Low archive compression (Hybrid Columnar Compression)                                            |
| COMP_BLOCK                  | NUMBER | 64      | Compressed block                                                                                 |
| COMP_LOB_HIGH               | NUMBER | 128     | High compression level for LOB operations                                                        |
| COMP_LOB_MEDIUM             | NUMBER | 256     | Medium compression level for LOB operations                                                      |
| COMP_LOB_LOW                | NUMBER | 512     | Low compression level for LOB operations                                                         |
| COMP_INDEX_ADVANCED_HIGH    | NUMBER | 1024    | High compression level for indexes                                                               |
| COMP_INDEX_ADVANCED_LOW     | NUMBER | 2048    | Low compression level for indexes                                                                |
| COMP_RATIO_LOB_MINROWS      | NUMBER | 1000    | Minimum required number of LOBs in the object for which LOB compression ratio is to be estimated |
| COMP_BASIC                  | NUMBER | 4096    | Basic table compression                                                                          |
| COMP_RATIO_LOB_MAXROWS      | NUMBER | 5000    | Maximum number of LOBs used to compute the LOB compression ratio                                 |
| COMP_INMEMORY_NOCOMPRESS    | NUMBER | 8192    | In-Memory with no compression                                                                    |
| COMP_INMEMORY_DML           | NUMBER | 16384   | In-Memory compression level for DML                                                              |
| COMP_INMEMORY_QUERY_LOW     | NUMBER | 32768   | In-Memory compression level optimized for query performance                                      |
| COMP_INMEMORY_QUERY_HIGH    | NUMBER | 65536   | In-Memory compression level optimized on query performance as well as space saving               |
| COMP_INMEMORY_CAPACITY_LOW  | NUMBER | 131072  | In-Memory low compression level optimizing for capacity                                          |
| COMP_INMEMORY_CAPACITY_HIGH | NUMBER | 262144  | In-Memory high compression level optimizing for capacity                                         |
| COMP_RATIO_MINROWS          | NUMBER | 1000000 | Minimum required number of rows in the object for which HCC ratio is to be estimated             |

**Table 39-1 (Cont.) DBMS\_COMPRESSION Constants - Compression Types**

| Constant           | Type        | Value | Description                                                                 |
|--------------------|-------------|-------|-----------------------------------------------------------------------------|
| COMP_RATIO_ALLROWS | NUMBER      | -1    | To indicate the use of all the rows in the object to estimate HCC ratio     |
| OBJTYPE_TABLE      | PLS_INTEGER | 1     | Identifies the object whose compression ratio is estimated as of type table |
| OBJTYPE_INDEX      | PLS_INTEGER | 2     | Identifies the object whose compression ratio is estimated as of type index |

**Note:**

Hybrid columnar compression is a feature of certain Oracle storage systems. See *Oracle Database Concepts* for more information.

## 39.4 DBMS\_COMPRESSION Data Structures

The DBMS\_COMPRESSION package defines a RECORD type and a TABLE type.

### RECORD TYPES

[COMPREC Record Type](#)

### TABLE TYPES

[COMPRECLIST Table Type](#)

### 39.4.1 COMPREC Record Type

The COMPREC record type is a record for calculating an individual index compression ratio on a table.

#### Syntax

```
TYPE COMPREC IS RECORD(  
    ownname          varchar2(255),  
    objname           varchar2(255),  
    blkcnt_cmp        PLS_INTEGER,  
    blkcnt_uncmp      PLS_INTEGER,  
    row_cmp            PLS_INTEGER,  
    row_uncmp         PLS_INTEGER,  
    cmp_ratio         NUMBER,  
    objtype           PLS_INTEGER);
```

## Fields

**Table 39-2 COMPREC Attributes**

| Field         | Description                                                    |
|---------------|----------------------------------------------------------------|
| ownname       | Schema of the object owner                                     |
| objname       | Name of the object                                             |
| blkcnt_cmp    | Number of blocks used by the compressed sample of the object   |
| blkcnt_uncomp | Number of blocks used by the uncompressed sample of the object |
| row_cmp       | Number of rows in a block in compressed sample of the object   |
| row_uncomp    | Number of rows in a block in uncompressed sample of the object |
| cmp_ratio     | Compression ratio, blkcnt_uncomp divided by blkcnt_cmp         |
| objtype       | Type of the object                                             |

## 39.4.2 COMPRECLIST Table Type

COMPRECLIST is a table type of the COMPREC Record Type.

### Syntax

```
TYPE compreclist IS TABLE OF comprec;
```

### Related Topics

- [COMPREC Record Type](#)  
The COMPREC record type is a record for calculating an individual index compression ratio on a table.

## 39.5 Summary of DBMS\_COMPRESSION Subprograms

The DBMS\_COMPRESSION package uses the GET\_COMPRESSION\_RATIO Procedure and GET\_COMPRESSION\_TYPE Function subprograms.

**Table 39-3 DBMS\_COMPRESSION Package Subprograms**

| Subprogram                                      | Description                                                                                       |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <a href="#">GET_COMPRESSION_RATIO Procedure</a> | Analyzes the compression ratio of a table, and gives information about compressibility of a table |
| <a href="#">GET_COMPRESSION_TYPE Function</a>   | Returns the compression type for a specified row                                                  |

## 39.5.1 GET\_COMPRESSION\_RATIO Procedure

This procedure analyzes the compression ratio of a table or an index, and gives information about compressibility of the object. Various parameters can be provided by the user to selectively analyze different compression types.

### Syntax

Get compression ratio for an object (table or index, default is table):

```
DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname      IN      VARCHAR2,
    ownname             IN      VARCHAR2,
    objname             IN      VARCHAR2,
    subobjname          IN      VARCHAR2,
    comptype            IN      NUMBER,
    blkcnt_cmp          OUT     PLS_INTEGER,
    blkcnt_uncmp        OUT     PLS_INTEGER,
    row_cmp             OUT     PLS_INTEGER,
    row_uncmp           OUT     PLS_INTEGER,
    cmp_ratio           OUT     NUMBER,
    comptype_str        OUT     VARCHAR2,
    subset_numrows      IN      NUMBER DEFAULT COMP_RATIO_MINROWS,
    objtype             IN      PLS_INTEGER DEFAULT OBJTYPE_TABLE);
```

Get compression ratio for LOBs:

```
DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname      IN      VARCHAR2,
    tabowner            IN      VARCHAR2,
    tabname             IN      VARCHAR2,
    lobname             IN      VARCHAR2,
    partname            IN      VARCHAR2,
    comptype            IN      NUMBER,
    blkcnt_cmp          OUT     PLS_INTEGER,
    blkcnt_uncmp        OUT     PLS_INTEGER,
    lobcnt              OUT     PLS_INTEGER,
    cmp_ratio           OUT     NUMBER,
    comptype_str        OUT     VARCHAR2,
    subset_numrows      IN      number DEFAULT COMP_RATIO_LOB_MAXROWS);
```

Get compression ratio for all indexes on a table. The compression ratios are returned as a collection.

```
DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname      IN      VARCHAR2,
    ownname             IN      VARCHAR2,
    tabname             IN      VARCHAR2,
    comptype            IN      NUMBER,
    index_cr            OUT     DBMS_COMPRESSION.COMPRECLIST,
    comptype_str        OUT     VARCHAR2,
    subset_numrows      IN      NUMBER DEFAULT COMP_RATIO_INDEX_MINROWS);
```

## Parameters

**Table 39-4 GET\_COMPRESSION\_RATIO Procedure Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scratchtbsname     | Temporary scratch tablespace that can be used for analysis                                                                                                                                                                                                                                                                                                                                |
| ownname / tabowner | Schema of the table to analyze                                                                                                                                                                                                                                                                                                                                                            |
| tabname            | Name of the table to analyze                                                                                                                                                                                                                                                                                                                                                              |
| objname            | Name of the object                                                                                                                                                                                                                                                                                                                                                                        |
| subobjname         | Name of the partition or sub-partition of the object                                                                                                                                                                                                                                                                                                                                      |
| comptype           | Compression types for which analysis should be performed<br>When the object is an index, only the following compression types are valid: COMP_INDEX_ADVANCED_HIGH (value 1024) and COMP_INDEX_ADVANCED_LOW (value 2048).<br><b>Note:</b> The following compression types cannot be specified in this parameter for any type of object: COMP_BLOCK (value 64) and COMP_BASIC (value 4096). |
| blkcnt_cmp         | Number of blocks used by compressed sample of the table                                                                                                                                                                                                                                                                                                                                   |
| blkcnt_uncmp       | Number of blocks used by uncompressed sample of the table                                                                                                                                                                                                                                                                                                                                 |
| row_cmp            | Number of rows in a block in compressed sample of the table                                                                                                                                                                                                                                                                                                                               |
| row_uncmp          | Number of rows in a block in uncompressed sample of the table                                                                                                                                                                                                                                                                                                                             |
| cmp_ratio          | Compression ratio, blkcnt_uncmp divided by blkcnt_cmp                                                                                                                                                                                                                                                                                                                                     |
| comptype_str       | String describing the compression type                                                                                                                                                                                                                                                                                                                                                    |
| subset_numrows     | Number of rows sampled to estimate compression ratio.                                                                                                                                                                                                                                                                                                                                     |
| objtype            | Type of the object, either OBJTYPE_TABLE or OBJTYPE_INDEX                                                                                                                                                                                                                                                                                                                                 |
| lobname            | Name of the LOB column                                                                                                                                                                                                                                                                                                                                                                    |
| partname           | In case of partitioned tables, the related partition name                                                                                                                                                                                                                                                                                                                                 |
| lobcnt             | Number of lobbs actually sampled to estimate compression ratio                                                                                                                                                                                                                                                                                                                            |
| index_cr           | List of indexes and their estimated compression ratios                                                                                                                                                                                                                                                                                                                                    |

## Examples

The following example shows how to estimate the compression ratio for advanced row compression:

```
SET SERVEROUTPUT ON
DECLARE
  l_blkcnt_cmp    PLS_INTEGER;
  l_blkcnt_uncmp  PLS_INTEGER;
  l_row_cmp       PLS_INTEGER;
  l_row_uncmp     PLS_INTEGER;
  l_cmp_ratio     NUMBER;
  l_comptype_str  VARCHAR2(32767);
BEGIN
  DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname => 'USERS' ,
    ownname        => 'TEST' ,
```

```

objname      => 'SALES' ,
subobjname   => NULL ,
comptype     => DBMS_COMPRESSION.COMP_ADVANCED,
blkcnt_cmp   => 1_blkcnt_cmp,
blkcnt_uncmp => 1_blkcnt_uncmp,
row_cmp      => 1_row_cmp,
row_uncmp    => 1_row_uncmp,
cmp_ratio    => 1_cmp_ratio,
comptype_str => 1_comptype_str,
subset_numrows => DBMS_COMPRESSION.comp_ratio_minrows,
objtype      => DBMS_COMPRESSION.objtype_table
);
DBMS_OUTPUT.put_line( 'Number of blocks used by the compressed sample of the
object      : ' || 1_blkcnt_cmp);
DBMS_OUTPUT.put_line( 'Number of blocks used by the uncompressed sample of
the object   : ' || 1_blkcnt_uncmp);
DBMS_OUTPUT.put_line( 'Number of rows in a block in compressed sample of the
object      : ' || 1_row_cmp);
DBMS_OUTPUT.put_line( 'Number of rows in a block in uncompressed sample of
the object   : ' || 1_row_uncmp);
DBMS_OUTPUT.put_line( 'Estimated Compression Ratio of
Sample      : ' || 1_cmp_ratio);
DBMS_OUTPUT.put_line( 'Compression Type                               : ' ||
1_comptype_str);
END;
/

```

#### Output of compression advisor estimate for advanced row compression (entire table):

```

Number of blocks used by the compressed sample of the object      : 165
Number of blocks used by the uncompressed sample of the object    : 629
Number of rows in a block in compressed sample of the object      : 599
Number of rows in a block in uncompressed sample of the object    : 157
Estimated Compression Ratio of Sample                            : 3.8
Compression Type                                                : "Compress Advanced"

```

The following example shows how to estimate the compression ratio for advanced index compression (Low):

```

SET SERVEROUTPUT ON
DECLARE
  1_blkcnt_cmp      PLS_INTEGER;
  1_blkcnt_uncmp    PLS_INTEGER;
  1_row_cmp         PLS_INTEGER;
  1_row_uncmp       PLS_INTEGER;
  1_cmp_ratio       NUMBER;
  1_comptype_str    VARCHAR2(32767);
BEGIN
  DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname => 'USERS' ,
    ownname        => 'TEST' ,
    objname        => 'SALES_IDX' ,
    subobjname     => NULL ,
    comptype       => DBMS_COMPRESSION.COMP_INDEX_ADVANCED_LOW,
    blkcnt_cmp     => 1_blkcnt_cmp,
    blkcnt_uncmp   => 1_blkcnt_uncmp,

```

```

row_cmp      =>      1_row_cmp,
row_uncmp    =>      1_row_uncmp,
cmp_ratio    =>      1_cmp_ratio,
comptype_str =>      1_comptype_str,
subset_numrows =>    DBMS_COMPRESSION.comp_ratio_minrows,
objtype      =>      DBMS_COMPRESSION.objtype_index
);
DBMS_OUTPUT.put_line( 'Number of blocks used by the compressed sample of the
object      : ' || 1_blkcnt_cmp);
DBMS_OUTPUT.put_line( 'Number of blocks used by the uncompressed sample of
the object : ' || 1_blkcnt_uncmp);
DBMS_OUTPUT.put_line( 'Number of rows in a block in compressed sample of the
object      : ' || 1_row_cmp);
DBMS_OUTPUT.put_line( 'Number of rows in a block in uncompressed sample of
the object : ' || 1_row_uncmp);
DBMS_OUTPUT.put_line( 'Estimated Compression Ratio of
Sample      : ' || 1_cmp_ratio);
DBMS_OUTPUT.put_line( 'Compression Type                : ' ||
1_comptype_str);
END;
/

```

#### Output of compression advisor estimate for advanced index compression (Low):

```

Number of blocks used by the compressed sample of the object      : 243
Number of blocks used by the uncompressed sample of the object    : 539
Number of rows in a block in compressed sample of the object      : 499
Number of rows in a block in uncompressed sample of the object    : 145
Estimated Compression Ratio of Sample                            : 2.2
Compression Type                                                  : "Compress Advanced Low"

```

#### The following example shows how to estimate the compression ratio for advanced LOB compression (Medium):

```

SET SERVEROUTPUT ON
DECLARE
  1_blkcnt_cmp      PLS_INTEGER;
  1_blkcnt_uncmp    PLS_INTEGER;
  1_row_cmp         PLS_INTEGER;
  1_lobcnt          PLS_INTEGER;
  1_cmp_ratio       NUMBER;
  1_comptype_str    VARCHAR2(32767);
BEGIN
  DBMS_COMPRESSION.GET_COMPRESSION_RATIO (
    scratchtbsname => 'USERS' ,
    tabowner       => 'TEST' ,
    tabname        => 'PARTS' ,
    lobname        => 'PART_DESCRIPTION' ,
    partname       => NULL ,
    comptype       => DBMS_COMPRESSION.COMP_LOB_MEDIUM,
    blkcnt_cmp     => 1_blkcnt_cmp,
    blkcnt_uncmp   => 1_blkcnt_uncmp,
    row_cmp        => 1_row_cmp,
    lobcnt         => 1_lobcnt,
    cmp_ratio      => 1_cmp_ratio,
    comptype_str   => 1_comptype_str,

```

```

        subset_numrows => DBMS_COMPRESSION.comp_ratio_lob_maxrows
    );
    DBMS_OUTPUT.put_line( 'Number of blocks used by the compressed sample of the
object      : ' || 1_blkcnt_cmp);
    DBMS_OUTPUT.put_line( 'Number of blocks used by the uncompressed sample of
the object  : ' || 1_blkcnt_uncmp);
    DBMS_OUTPUT.put_line( 'Number of rows in a block in compressed sample of the
object      : ' || 1_row_cmp);
    DBMS_OUTPUT.put_line( 'Number of LOBS actually
sampled      : ' || 1_lobcnt);
    DBMS_OUTPUT.put_line( 'Estimated Compression Ratio of
Sample       : ' || 1_cmp_ratio);
    DBMS_OUTPUT.put_line( 'Compression
Type                                                : ' || 1_comptype_str);
END;
/

```

#### Output of compression advisor estimate for advanced LOB compression (Medium):

```

Number of blocks used by the compressed sample of the object      : 199
Number of blocks used by the uncompressed sample of the object    : 389
Number of rows in a block in compressed sample of the object      : 293
Number of LOBS actually sampled                                   : 55
Estimated Compression Ratio of Sample                            : 1.9
Compression Type                                                  : "Compress Medium"

```

#### Usage Notes

The procedure creates different tables in the scratch tablespace and runs analysis on these objects. It does not modify anything in the user-specified tables.

## 39.5.2 GET\_COMPRESSION\_TYPE Function

This function returns the compression type for a specified row. If the row is chained, the function returns the compression type of the head piece only, and does not examine the intermediate or the tail piece since head pieces can be differently compressed.

#### Syntax

```

DBMS_COMPRESSION.GET_COMPRESSION_TYPE (
    ownname      IN   VARCHAR2,
    tabname      IN   VARCHAR2,
    row_id       IN   ROWID,
    subobjname   IN   VARCHAR2 DEFAULT NULL)
RETURN NUMBER;

```

#### Parameters

**Table 39-5 GET\_COMPRESSION\_TYPE Function Parameters**

| Parameter  | Description                                 |
|------------|---------------------------------------------|
| ownname    | Schema name of the table                    |
| tabname    | Name of table                               |
| rowid      | Rowid of the row                            |
| subobjname | Name of the table partition or subpartition |

### Return Values

Flag to indicate the compression type (see [Table 39-1](#)).

# DBMS\_CONNECTION\_POOL

The `DBMS_CONNECTION_POOL` package provides an interface to manage Database Resident Connection Pool.

- [Summary of DBMS\\_CONNECTION\\_POOL Subprograms](#)

## 40.1 Summary of DBMS\_CONNECTION\_POOL Subprograms

This table lists the `DBMS_CONNECTION_POOL` subprograms in alphabetical order and briefly describes them.

**Table 40-1 DBMS\_CONNECTION\_POOL Package Subprograms**

| Subprogram                                 | Description                                                                                                                        |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ALTER_PARAM Procedure</a>      | Alters a specific configuration parameter as a standalone unit and does not affect other parameters                                |
| <a href="#">CONFIGURE_POOL Procedure</a>   | Configures the pool with advanced options                                                                                          |
| <a href="#">START_POOL Procedure</a>       | Starts the pool for operations. It is only after this call that the pool could be used by connection clients for creating sessions |
| <a href="#">STOP_POOL Procedure</a>        | Stops the pool and makes it unavailable for the registered connection clients                                                      |
| <a href="#">RESTORE_DEFAULTS Procedure</a> | Restores the pool to default settings                                                                                              |

### 40.1.1 ALTER\_PARAM Procedure

This procedure alters a specific Database Resident Connection Pool (DRCP) configuration parameter as a standalone unit, and does not affect other parameters.

#### Syntax

```
DBMS_CONNECTION_POOL.ALTER_PARAM (
  pool_name      IN  VARCHAR2 DEFAULT 'SYS_DEFAULT_CONNECTION_POOL',
  param_name     IN  VARCHAR2,
  param_value    IN  VARCHAR2);
```

## Parameters

**Table 40-2 ALTER\_PARAM Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pool_name   | Pool to be configured.<br>Currently only the default pool name is supported.                                                                                                                                                                                                                                 |
| param_name  | Any parameter name from CONFIGURE_POOL.<br>An administrator can also use the ALTER_PARAM() procedure to set the DRCP parameters NUM_CBROK and MAXCONN_CBROK if the database initialization parameter connection_brokers is not set. Using connection_brokers is the recommended way to set these parameters. |
| param_value | Parameter value for param_name.                                                                                                                                                                                                                                                                              |

### See Also:

For the list and description of all the DRCP parameters that can be configured using this procedure, see the *Oracle Database Administrator's Guide*.

## Exceptions

**Table 40-3 ALTER\_PARAM Procedure Exceptions**

| Exception | Description                                           |
|-----------|-------------------------------------------------------|
| ORA-56500 | Connection pool not found                             |
| ORA-56504 | Invalid connection pool configuration parameter name  |
| ORA-56505 | Invalid connection pool configuration parameter value |
| ORA-56507 | Connection pool alter configuration failed            |

## Examples

```
DBMS_CONNECTION_POOL.ALTER_PARAM(
    'SYS_DEFAULT_CONNECTION_POOL', 'MAX_LIFETIME_SESSION', '120');
```

## 40.1.2 CONFIGURE\_POOL Procedure

This procedure configures the pool with advanced options.

### Syntax

```
DBMS_CONNECTION_POOL.CONFIGURE_POOL (
    pool_name          IN VARCHAR2 DEFAULT 'SYS_DEFAULT_CONNECTION_POOL',
    minsize            IN NUMBER   DEFAULT 4,
    maxsize            IN NUMBER   DEFAULT 40,
    incrsz            IN NUMBER   DEFAULT 2,
    session_cached_cursors IN NUMBER DEFAULT 20,
    inactivity_timeout IN NUMBER   DEFAULT 300,
    max_think_time     IN NUMBER   DEFAULT 120,
    max_use_session    IN NUMBER   DEFAULT 500000,
```

```

max_lifetime_session    IN NUMBER    DEFAULT 86400,
max_txn_think_time      IN NUMBER);

```

## Parameters

**Table 40-4** CONFIGURE\_POOL Procedure Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pool_name              | Pool to be configured. Currently only the default pool name is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| minsize                | Minimum number of pooled servers in the pool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| maxsize                | Maximum allowed pooled servers in the pool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| incrsize               | Pool would increment by this number of pooled server when pooled server are unavailable at application request time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| session_cached_cursors | Turn on SESSION_CACHED_CURSORS for all connections in the pool. This is an existing init.ora parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| inactivity_timeout     | TTL (Time to live) for an idle session in the pool. This parameter helps to shrink the pool when it is not used to its maximum capacity. If a connection remains in the pool idle for this time, it is killed.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| max_think_time         | The maximum time of inactivity, in seconds, for a client after it obtains a pooled server from the pool with no open transactions in it. After obtaining a pooled server from the pool, if the client application does not issue a database call for the time specified by MAX_THINK_TIME, the pooled server is freed and the client connection is terminated.                                                                                                                                                                                                                                                                          |
| max_use_session        | Maximum number of times a connection can be taken and released to the pool                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| max_lifetime_session   | TTL (Time to live) for a pooled session                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| max_txn_think_time     | The maximum time of inactivity, in seconds, for a client after it obtains a pooled server from the pool with an open transaction. After obtaining the pooled server from the pool, if the client application does not issue a database call for the time specified by MAX_TXN_THINK_TIME, then the pooled server is freed, and the client connection is terminated. The default value of this parameter is the value of the MAX_THINK_TIME parameter. Applications can set the value of the MAX_TXN_THINK_TIME parameter to a value higher than the MAX_THINK_TIME value to allow more time for the connections with open transactions. |

## Exceptions

**Table 40-5** CONFIGURE\_POOL Procedure Exceptions

| Exception | Description                                |
|-----------|--------------------------------------------|
| ORA-56500 | Connection pool not found                  |
| ORA-56507 | Connection pool alter configuration failed |

## Usage Notes

- All expressions of time are in seconds
- All of the parameters should be set based on statistical request patterns.

- `minsize` should be set keeping in mind that it puts a lower bound on server resource consumption. This is to prevent the timeout from dragging the pool too low, because of a brief period of inactivity.
- `maxsize` should be set keeping in mind that it puts an upper bound on concurrency and response-times and also server resource consumption.
- `session_cached_cursors` is typically set to the number of most frequently used statements. It occupies cursor resource on the server
- In doubt, do not set the `increment` and `inactivity_timeout`. The pool will have reasonable defaults.
- `max_use_session` and `max_lifetime_session` allow for software rejuvenation or defensive approaches to potential bugs, leaks, accumulations, and like problems, by getting brand new sessions once in a while.
- The connection pool reserves 5% of the pooled servers for authentication, and at least one pooled server is always reserved for authentication. When setting the `maxsize` parameter, ensure that there are enough pooled servers for both authentication and connections.

### 40.1.3 START\_POOL Procedure

This procedure starts the pool for operations. It is only after this call that the pool could be used by connection classes for creating sessions.

#### Syntax

```
DBMS_CONNECTION_POOL.START_POOL (
    pool_name IN VARCHAR2 DEFAULT 'SYS_DEFAULT_CONNECTION_POOL');
```

#### Parameters

**Table 40-6 START\_POOL Procedure Parameters**

| Parameter              | Description                                                            |
|------------------------|------------------------------------------------------------------------|
| <code>pool_name</code> | Pool to be started. Currently only the default pool name is supported. |

#### Exceptions

**Table 40-7 START\_POOL Procedure Exceptions**

| Exception | Description                    |
|-----------|--------------------------------|
| ORA-56500 | Connection pool not found      |
| ORA-56501 | Connection pool startup failed |

#### Usage Notes

If the instance is restarted (shutdown followed by startup), the pool is automatically started.

## 40.1.4 STOP\_POOL Procedure

This procedure stops the pool and makes it unavailable for the registered connection classes.

### Syntax

```
DBMS_CONNECTION_POOL.STOP_POOL (  
    pool_name    IN    VARCHAR2 DEFAULT 'SYS_DEFAULT_CONNECTION_POOL');
```

### Parameters

**Table 40-8 STOP\_POOL Procedure Parameters**

| Parameter | Description                                                            |
|-----------|------------------------------------------------------------------------|
| pool_name | Pool to be stopped. Currently only the default pool name is supported. |

### Exceptions

**Table 40-9 STOP\_POOL Procedure Exceptions**

| Exception | Description                     |
|-----------|---------------------------------|
| ORA-56500 | Connection pool not found       |
| ORA-56506 | Connection pool shutdown failed |

### Usage Notes

This stops the pool and takes it offline. This does not destroy the persistent data (such as, the pool name and configuration parameters) associated with the pool.

## 40.1.5 RESTORE\_DEFAULTS Procedure

This procedure restores the pool to default settings.

### Syntax

```
DBMS_CONNECTION_POOL.RESTORE_DEFAULTS (  
    pool_name    IN    VARCHAR2 DEFAULT 'SYS_DEFAULT_CONNECTION_POOL');
```

### Parameters

**Table 40-10 RESTORE\_DEFAULTS Procedure Parameters**

| Parameter | Description                                                             |
|-----------|-------------------------------------------------------------------------|
| pool_name | Pool to be restored. Currently only the default pool name is supported. |

## Exceptions

**Table 40-11** RESTORE\_DEFAULTS Procedure Exceptions

| Exception | Description                                |
|-----------|--------------------------------------------|
| ORA-56500 | Connection pool not found                  |
| ORA-56507 | Connection pool alter configuration failed |

## Usage Notes

If the instance is restarted (shutdown followed by startup), the pool is automatically started.

# DBMS\_CQ\_NOTIFICATION

The `DBMS_CQ_NOTIFICATION` package is part of the database change notification feature that provides the functionality to create registration on queries designated by a client application and so to receive notifications in response to DML or DDL changes on the objects associated with the queries. The notifications are published by the database when the DML or DDL transaction commits.

## See Also:

*Oracle Database Development Guide* regarding implementing database change notification.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Operational Notes](#)
- [Examples](#)
- [Data Structures](#)
- [Summary of DBMS\\_CQ\\_NOTIFICATION Subprograms](#)

## 41.1 DBMS\_CQ\_NOTIFICATION Overview

The `DBMS_CQ_NOTIFICATION` package provides PL/SQL based registration interfaces. A client can use this interface to create registrations on queries based on objects of interest and specify a PL/SQL callback handler to receive notifications. In case of object level registration, when a transaction changes any of the objects associated with the registered queries and | COMMITs, the PL/SQL callback, specified during registration for those objects, is invoked. The application can define client-specific processing inside the implementation of its PL/SQL callback handler.

The interface lets you define a registration block (using a mechanism similar to a `BEGIN-END` block). The recipient of notifications namely the name of the PL/SQL callback handler and a few other registration properties like time-outs can be specified during the `BEGIN` phase. Any queries executed subsequently (inside the registration block) are considered "interesting queries" and objects referenced by those queries during query execution are registered. The registration is completed by `ENDING` the registration block. The registration block lets you create new registrations or add objects to existing registrations.

When a registration is created through the PL/SQL interface, a unique registration ID is assigned to the registration by the RDBMS. The client application can use the registration ID to keep track of registrations created by it. When a notification is published by the RDBMS, the registration ID will be part of the notification.

## Typical Applications

This functionality is useful for example to applications that cache query result sets on mostly read-only objects in the mid-tier to avoid network round trips to the database. Such an application can create a registration on the queries it is interested in caching. On changes to objects referenced inside those queries, the database publishes a notification when the underlying transaction commits. In response to the notification, the mid-tier application can refresh its cache by re-executing the query/queries.

## 41.2 DBMS\_CQ\_NOTIFICATION Security Model

The `DBMS_CQ_NOTIFICATION` package requires that the user have the `CHANGE NOTIFICATION` system privilege in order to receive notifications, and be granted `EXECUTE` privilege on the `DBMS_CQ_NOTIFICATION` package.

In addition the user is required to have `SELECT` or `READ` privileges on all objects to be registered. Note that if the `SELECT` or `READ` privilege on an object was granted at the time of registration creation but lost subsequently (due to a revoke), then the registration will be purged and a notification to that effect will be published.

## 41.3 DBMS\_CQ\_NOTIFICATION Constants

`DBMS_CQ_NOTIFICATION` constants are used as flag parameters either during registration or when received during the notification.

The `DBMS_CQ_NOTIFICATION` package has sets of constants:

- `EVENT_STARTUP`, `EVENT_SHUTDOWN`, `EVENT_SHUTDOWN_ANY`, `EVENT_DEREG` describe the type of the notification published by the database.
- `INSERTOP`, `DELETEOP`, `UPDATEOP`, `ALTEROP`, `DROPOP` and `UNKNOWNOP` describe the type of operation on a table (during a notification published by the database).
- `QOS_RELIABLE`, `QOS_DEREG_NFY`, `QOS_ROWIDS` describe registration Quality of Service properties that the client requires. These are specified during registration.

The constants are shown in the following table.

**Table 41-1 DBMS\_CQ\_NOTIFICATION Constants**

| Name                            | Type                        | Value | Description                                                                                  |
|---------------------------------|-----------------------------|-------|----------------------------------------------------------------------------------------------|
| <code>ALL_OPERATIONS</code>     | <code>BINARY_INTEGER</code> | 0     | Interested in being notified on all operations, specified as a parameter during registration |
| <code>ALL_ROWS</code>           | <code>BINARY_INTEGER</code> | 1     | All rows within the table may have been potentially modified                                 |
| <code>EVENT_STARTUP</code>      | <code>BINARY_INTEGER</code> | 1     | Instance startup notification                                                                |
| <code>EVENT_SHUTDOWN</code>     | <code>BINARY_INTEGER</code> | 2     | Instance shutdown notification                                                               |
| <code>EVENT_SHUTDOWN_ANY</code> | <code>BINARY_INTEGER</code> | 3     | Any instance shutdown when running Oracle Real Application Clusters (Oracle RAC)             |
| <code>EVENT_DEREG</code>        | <code>BINARY_INTEGER</code> | 5     | Registration has been removed                                                                |
| <code>EVENT_OBJCHANGE</code>    | <code>BINARY_INTEGER</code> | 6     | Notification for object change                                                               |

**Table 41-1 (Cont.) DBMS\_CQ\_NOTIFICATION Constants**

| Name                       | Type           | Value | Description                                                                                                                                                                                        |
|----------------------------|----------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EVENT_QUERYCHANGE          | BINARY_INTEGER | 7     | Notification for query result set change                                                                                                                                                           |
| INSERTOP                   | BINARY_INTEGER | 2     | Insert operation                                                                                                                                                                                   |
| UPDATEOP                   | BINARY_INTEGER | 4     | Update operation                                                                                                                                                                                   |
| DELETEOP                   | BINARY_INTEGER | 8     | Delete operation                                                                                                                                                                                   |
| ALTEROP                    | BINARY_INTEGER | 16    | Table altered                                                                                                                                                                                      |
| DROPOP                     | BINARY_INTEGER | 32    | Table dropped                                                                                                                                                                                      |
| UNKNOWNOP                  | BINARY_INTEGER | 64    | Unknown operation                                                                                                                                                                                  |
| QOS_RELIABLE               | BINARY_INTEGER | 1     | Reliable or persistent notification. Also implies that the notifications will be inserted into the persistent storage atomically with the committing transaction that results in an object change. |
| QOS_DEREG_NFY              | BINARY_INTEGER | 2     | Purge registration on first notification                                                                                                                                                           |
| QOS_ROWIDS                 | BINARY_INTEGER | 4     | Require rowids of modified rows                                                                                                                                                                    |
| QOS_QUERY                  | BINARY_INTEGER | 8     | Register at query granularity                                                                                                                                                                      |
| QOS_BEST_EFFORT            | BINARY_INTEGER | 16    | Best effort evaluation                                                                                                                                                                             |
| NTFN_GROUPING_CLASS_TIME   | BINARY_INTEGER | 1     | Group notifications by time                                                                                                                                                                        |
| NTFN_GROUPING_TYPE_SUMMARY | BINARY_INTEGER | 1     | Summary grouping of notifications                                                                                                                                                                  |
| NTFN_GROUPING_TYPE_LAST    | BINARY_INTEGER | 2     | Last notification in the group                                                                                                                                                                     |
| NTFN_GROUPING_FOREVER      | BINARY_INTEGER | -1    | Repeat notifications forever                                                                                                                                                                       |

## 41.4 DBMS\_CQ\_NOTIFICATION Operational Notes

The following are DBMS\_CQ\_NOTIFICATION operational notes.

### Object Level Registration

- The notifications are published by the database when a transaction changes the registered objects and `COMMITs`.
- All objects referenced in the queries executed inside the registration block starting from the previous `NEW_REG_START` or `ENABLE_REG` to `REG_END` are considered interesting objects and added to the registration.

### Query Result Change Registration

- The notifications are published by the database when a transaction changes the result set of the registered query and `COMMITs`.

### Troubleshooting

If you have created a registration and seem to not receive notifications when the underlying tables are changed, please check the following.

- Is the `job_queue_processes` parameter set to a nonzero value? This parameter needs to be configured to a nonzero value in order to receive PL/SQL notifications through the handler.
- Are the registrations being created as a non-SYS user?
- If you are attempting DML changes on the registered object, are you `COMMITTING` the transaction? Please note that the notifications are transactional and will be generated when the transaction `COMMITs`.
- It maybe possible that there are run-time errors during the execution of the PL/SQL callback due to implementation errors. If so, they would be logged to the trace file of the `JOBQ` process that attempts to execute the procedure. The trace file would be usually named `<ORACLE_SID>_j*_<PID>.trc.`

For example, if the `ORACLE_SID` is 'dbs1' and the process is 12483, the trace file might be named 'dbs1\_j000\_12483.trc.

Suppose a registration is created with 'chnf\_callback' as the notification handler and with `registration_id` 100. Let us suppose the user forgets to define the `chnf_callback` procedure. Then the `JOBQ` trace file might contain a message of the following form.

```
Runtime error during execution of PL/SQL cbk chnf_callback for reg CHNF100
Error in PLSQL notification of msgid:
Queue :
Consumer Name :
PLSQL function :chnf_callback
Exception Occured, Error msg:
ORA-00604: error occurred at recursive SQL level 2
ORA-06550: line 1, column 7:
PLS-00201: identifier 'CHNF_CALLBACK' must be declared
ORA-06550: line 1, column 7:
PL/SQL: Statement ignored
```

## 41.5 DBMS\_CQ\_NOTIFICATION Examples

Suppose that a mid-tier application has a lot of queries on the `HR.EMPLOYEES` table. If the `EMPLOYEES` table is infrequently updated, it can obtain better performance by caching rows from the table because that would avoid a round-trip to the backend database server and server side execution latency. Let us assume that the application has implemented a mid-tier HTTP listener that listens for notifications and updates the mid-tier cache in response to a notification.

### Object Change Registration Example

The `DBMS_CQ_NOTIFICATION` package can be utilized in this scenario to send notifications about changes to the table by means of the following steps:

1. Implement a mid-tier listener component of the cache management system (for example, using HTTP) that listens to notification messages sent from the database and refreshes the mid-tier cache in response to the notification.
2. Create a server side stored procedure to process notifications

```

CONNECT system;
Enter password: password
GRANT CHANGE NOTIFICATION TO hr;
GRANT EXECUTE ON DBMS_CQ_NOTIFICATION TO hr;

Rem Enable job queue processes to receive notifications.
ALTER SYSTEM SET "job_queue_processes"=2;

CONNECT hr;
Enter password: password
Rem Create a table to record notification events
CREATE TABLE nfevents(regid number, event_type number);

Rem create a table to record changes to registered tables
CREATE TABLE nftablechanges(regid number, table_name varchar2(100),
                             table_operation number);

Rem create a table to record rowids of changed rows.
CREATE TABLE nfrowchanges(regid number, table_name varchar2(100),
                           row_id varchar2(30));

Rem Create a PL/SQL callback handler to process notifications.
CREATE OR REPLACE PROCEDURE chnf_callback(ntfnds IN SYS.CHNF$_DESC) IS
    regid          NUMBER;
    tbname         VARCHAR2(60);
    event_type     NUMBER;
    numtables      NUMBER;
    operation_type  NUMBER;
    numrows        NUMBER;
    row_id         VARCHAR2(20);
BEGIN
    regid          := ntfnds.registration_id;
    numtables      := ntfnds.numtables;
    event_type     := ntfnds.event_type;

    INSERT INTO nfevents VALUES(regid, event_type);
    IF (event_type = DBMS_CQ_NOTIFICATION.EVENT_OBJCHANGE) THEN
        FOR i IN 1..numtables LOOP
            tbname          := ntfnds.table_desc_array(i).table_name;
            operation_type  := ntfnds.table_desc_array(i).Opflags;
            INSERT INTO nftablechanges VALUES(regid, tbname, operation_type);
            /* Send the table name and operation_type to client side listener using
UTL_HTTP */
            /* If interested in the rowids, obtain them as follows */
            IF (bitand(operation_type, DBMS_CQ_NOTIFICATION.ALL_ROWS) = 0) THEN
                numrows := ntfnds.table_desc_array(i).numrows;
            ELSE
                numrows :=0;    /* ROWID INFO NOT AVAILABLE */
            END IF;

            /* The body of the loop is not executed when numrows is ZERO */
            FOR j IN 1..numrows LOOP
                Row_id := ntfnds.table_desc_array(i).row_desc_array(j).row_id;
                INSERT INTO nfrowchanges VALUES(regid, tbname, Row_id);
                /* optionally Send out row_ids to client side listener using UTL_HTTP; */
            END LOOP;

        END LOOP;
    END IF;
    COMMIT;
END;
/

```

In Step 2 we can send as much information about the invalidation as the mid-tier application needs based on the information obtained from the notification descriptor.

#### Notes

- a. In the above example, a registration was created on the `EMPLOYEES` table with 'chnf\_callback' as the PL/SQL handler for notifications. During registration, the client specified reliable notifications (`QOS_RELIABLE`) and rowid notifications (`QOS_ROWIDS`)
- b. The handler accesses the table descriptor array from the notification descriptor only if the notification type is of `EVENT_OBJCHANGE`. In all other cases (e.g `EVENT_DEREG`, `EVENT_SHUTDOWN`), the table descriptor array should not be accessed.
- c. The handler accesses the row descriptor array from the table notification descriptor only if the `ALL_ROWS` bit is not set in the table operation flag. If the `ALL_ROWS` bit is set in the table operation flag, then it means that all rows within the table may have been potentially modified. In addition to operations like `TRUNCATE` that affect all rows in the tables, this bit may also be set if individual rowids have been rolled up into a `FULL` table invalidation.

This can occur if too many rows were modified on a given table in a single transaction (more than 80) or the total shared memory consumption due to rowids on the RDBMS is determined too large (exceeds 1% of the dynamic shared pool size). In this case, the recipient must conservatively assume that the entire table has been invalidated and the callback/application must be able to handle this condition.

Also note that the implementation of the user defined callback is up to the developer. In the above example, the callback was used to record event details into database tables. The application can additionally send the notification details to a mid-tier `HTTP` listener of its cache management system (as in the example) using `UTL_HTTP`. The listener could then refresh its cache by querying from the back-end database.

3. Create a registrations on the tables that we wish to be notified about. We pass in the previously defined procedure name (chnf\_callback) as the name of the server side PL/SQL procedure to be executed when a notification is generated.

```
Rem Create a REGISTRATION on the EMPLOYEES TABLE
DECLARE
    REGDS      SYS.CHNF$_REG_INFO;
    regid      NUMBER;
    mgr_id     NUMBER;
    dept_id    NUMBER;
    qosflags   NUMBER;
BEGIN
    qosflags := DBMS_CQ_NOTIFICATION.QOS_RELIABLE +
                DBMS_CQ_NOTIFICATION.QOS_ROWIDS;
    REGDS := SYS.CHNF$_REG_INFO ('chnf_callback', qosflags, 0,0,0);
    regid := DBMS_CQ_NOTIFICATION.NEW_REG_START (REGDS);
    SELECT manager_id INTO mgr_id FROM EMPLOYEES WHERE employee_id = 200;
    DBMS_CQ_NOTIFICATION.REG_END;
END;
/
```

Once the registration is created in Step 3 above, the server side PL/SQL procedure defined in Step 2 is executed in response to any `COMMITTED` changes to the `HR.EMPLOYEES` table. As an example, let us assume that the following update is performed on the employees table.

```
UPDATE employees SET salary=salary*1.05 WHERE employee_id=203;COMMIT;
```

Once the notification is processed, you will find rows which might look like the following in the nfevents, nftablechanges and nfrowchanges tables.

```
SQL> SELECT * FROM nfevents;
```

| REGID | EVENT_TYPE |
|-------|------------|
| 20045 | 6          |

```
SQL> SELECT * FROM nftablechanges;
```

| REGID | TABLE_NAME   | TABLE_OPERATION |
|-------|--------------|-----------------|
| 20045 | HR.EMPLOYEES | 4               |

```
SQL> select * from nfrowchanges;
```

| REGID | TABLE_NAME   | ROW_ID             |
|-------|--------------|--------------------|
| 20045 | HR.EMPLOYEES | AAAKB/AABAAAJ8zAAF |

## Query Result Change Registration Example

### 1. Creating a Callback

```
CONNECT system;
Enter password: password
GRANT CHANGE NOTIFICATION TO hr;
GRANT EXECUTE ON DBMS_CQ_NOTIFICATION TO hr;
CONNECT hr;
Enter password: password
Rem Create a table to record notification events
CREATE TABLE nfevents(regid NUMBER, event_type NUMBER);

Rem Create a table to record notification queries
CREATE TABLE nfqueries (qid NUMBER, qop NUMBER);

Rem Create a table to record changes to registered tables
CREATE TABLE nftablechanges(
    qid          NUMBER,
    table_name   VARCHAR2(100),
    table_operation  NUMBER);

Rem Create a table to record rowids of changed rows.
CREATE TABLE nfrowchanges(
    qid          NUMBER,
    table_name   VARCHAR2(100),
    row_id       VARCHAR2(2000));

CREATE OR REPLACE PROCEDURE chnf_callback
(ntfnds IN CQ_NOTIFICATION$_DESCRIPTOR)
IS
    regid          NUMBER;
    tbname         VARCHAR2(60);
    event_type     NUMBER;
    numtables      NUMBER;
    operation_type NUMBER;
    numrows        NUMBER;
    row_id         VARCHAR2(2000);
```

```

numqueries      NUMBER;
qid NUMBER;
qop NUMBER;

BEGIN
  regid := ntfnfs.registration_id;
  event_type := ntfnfs.event_type;
  INSERT INTO nfevents VALUES(regid, event_type);
  numqueries :=0;
  IF (event_type = DBMS_CQ_NOTIFICATION.EVENT_QUERYCHANGE) THEN
    numqueries := ntfnfs.query_desc_array.count;
    FOR i in 1..numqueries LOOP
      qid := ntfnfs.QUERY_DESC_ARRAY(i).queryid;
      qop := ntfnfs.QUERY_DESC_ARRAY(i).queryop;
      INSERT INTO nfqueries VALUES(qid, qop);
      numtables := 0;
      numtables := ntfnfs.QUERY_DESC_ARRAY(i).table_desc_array.count;
      FOR j IN 1..numtables LOOP
        tbname := ntfnfs.QUERY_DESC_ARRAY(i).table_desc_array(j).table_name;
        operation_type := ntfnfs.QUERY_DESC_ARRAY(i).table_desc_array(j).Opflags;
        INSERT INTO nftablechanges VALUES(qid, tbname, operation_type);
        IF (bitand(operation_type, DBMS_CQ_NOTIFICATION.ALL_ROWS) = 0)
        THEN
          numrows := ntfnfs.query_desc_array(i).table_desc_array(j).numrows;
        ELSE
          numrows :=0;    /* ROWID INFO NOT AVAILABLE */
        END IF;

        /* The body of the loop is not executed when numrows is ZERO */
        FOR k IN 1..numrows LOOP
          Row_id :=
ntfnfs.query_desc_array(i).table_desc_array(j).row_desc_array(k).row_id;
          INSERT INTO nfrowchanges VALUES(qid, tbname, Row_id);

        END LOOP;    /* loop over rows */
      END LOOP;    /* loop over tables */
    END LOOP;    /* loop over queries */
  END IF;
  COMMIT;
END;
/

```

## 2. Creates a query registration

```

DECLARE
  reginfo      cq_notification$_reg_info;
  mgr_id       NUMBER;
  dept_id      NUMBER;
  v_cursor     SYS_REFCURSOR;
  regid        NUMBER;
  qosflags     NUMBER;

BEGIN
  /* Register two queries for result-set-change notifications: */

  /* 1. Construct registration information.
   'chnf_callback' is name of notification handler.
   QOS_QUERY specifies result-set-change notifications. */

  qosflags := DBMS_CQ_NOTIFICATION.QOS_QUERY +
              DBMS_CQ_NOTIFICATION.QOS_ROWIDS;

```

```

    reginfo := cq_notification$_reg_info('chnf_callback', qosflags,0, 0, 0);

/* 2. Create registration */

    regid := DBMS_CQ_NOTIFICATION.NEW_REG_START(reginfo);

    OPEN v_cursor FOR
        SELECT DBMS_CQ_NOTIFICATION.CQ_NOTIFICATION_QUERYID, manager_id
        FROM HR.employees
        WHERE employee_id = 7902;
    CLOSE v_cursor;

    OPEN v_cursor for
        SELECT DBMS_CQ_NOTIFICATION.CQ_NOTIFICATION_QUERYID, department_id
        FROM HR.departments
        WHERE department_name = 'IT';
    CLOSE v_cursor;

    DBMS_CQ_NOTIFICATION.REG_END;
END;
/

```

3. After creating the query registrations, the output from USER\_CQ\_NOTIFICATION\_QUERIES would appear as follows.

```

SQL> SELECT queryid, regid, to_char(querytext)
       FROM user_cq_notification_queries;

    QUERYID      REGID
-----
TO_CHAR(QUERYTEXT)
-----
          22          41
SELECT HR.DEPARTMENTS.DEPARTMENT_ID FROM HR.DEPARTMENTS WHERE HR.DEPARTMENTS.
DEPARTMENT_NAME = 'IT'

          21          41
SELECT HR.EMPLOYEES.MANAGER_ID FROM HR.EMPLOYEES WHERE HR.EMPLOYEES.EMPLOYEE_
ID = 7902

```

Now, let us perform an UPDATE that changes the result of the query with queryid 22 by renaming the department with name 'IT' to FINANCE.

```

SQL> update departments set department_name = 'FINANCE' where department_name =
'IT';

```

1 row updated.

```

SQL> commit;

```

Commit complete.

Now we can query the notifications that we recorded in the callback.

```

SQL> select * from nfevents;

```

```

    REGID EVENT_TYPE
-----
          61          7

```

Event type 7 corresponds to EVENT\_QUERYCHANGE

```
SQL> select * from nfqueries;
```

```

      QID      QOP
-----
      42       7

```

Event type 7 corresponds to EVENT\_QUERYCHANGE

```
SQL> select * from nftablechanges;
```

```
SQL> select * from nftablechanges;
```

```

      REGID
-----
TABLE_NAME
-----
TABLE_OPERATION
-----
      42
HR.DEPARTMENTS
      4

```

TABLE\_OPERATION 4 corresponds to UPDATEOP

```
SQL> select * from nfrowchanges;
```

```

      REGID
-----
TABLE_NAME
-----
ROW_ID
-----
      61
HR.DEPARTMENTS
AAANKdAABAAALinAAF

```

## 41.6 DBMS\_CQ\_NOTIFICATION Data Structures

The DBMS\_CQ\_NOTIFICATION package defines several OBJECT types.

### OBJECT Types

- CQ\_NOTIFICATION\$\_DESCRIPTOR Object Type
- CQ\_NOTIFICATION\$\_QUERY Object Type
- CQ\_NOTIFICATION\$\_QUERY\_ARRAY Object (Array) Type
- CQ\_NOTIFICATION\$\_TABLE Object Type
- CQ\_NOTIFICATION\$\_TABLE\_ARRAY Object (Array) Type
- CQ\_NOTIFICATION\$\_ROW Object Type
- CQ\_NOTIFICATION\$\_ROW\_ARRAY Object (Array) Type
- CQ\_NOTIFICATION\$\_REG\_INFO Object Type

## 41.6.1 CQ\_NOTIFICATION\$\_DESCRIPTOR Object Type

This is the top level change notification descriptor type. It is a synonym for the `SYS.CHNF$_DESC` type.

### Syntax

```
TYPE SYS.CHNF$_DESC IS OBJECT(
    registration_id    NUMBER,
    transaction_id     RAW(8),
    dbname             VARCHAR2(30),
    event_type         NUMBER,
    numtables          NUMBER,
    table_desc_array   CQ_NOTIFICATION$_TABLE_ARRAY,
    query_desc_array   CQ_NOTIFICATION$_QUERY_ARRAY);
```

### Attributes

**Table 41-2 CQ\_NOTIFICATION\$\_DESCRIPTOR Object Type**

| Attribute        | Description                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| registration_id  | Registration ID returned during registration                                                                                                                                                                                                        |
| transaction_id   | Transaction ID. transaction_id of the transaction that made the change. Will be NULL unless the event_type is EVENT_OBJCHANGE or EVENT_QUERYCHANGE.                                                                                                 |
| dbname           | Name of database                                                                                                                                                                                                                                    |
| event_type       | Database event associated with the notification. Can be one of EVENT_OBJCHANGE (change to a registered object), EVENT_STARTUP, or EVENT_QUERYCHANGE, EVENT_SHUTDOWN or EVENT_DEREG (registration has been removed due to a timeout or other reason) |
| numtables        | Number of modified tables. Will be NULL unless the event_type is EVENT_OBJCHANGE.                                                                                                                                                                   |
| table_desc_array | Array of table descriptors. Will be NULL unless the event_type is EVENT_OBJCHANGE.                                                                                                                                                                  |
| query_desc_array | Array of queries changed. This will be NULL unless event_type is EVENT_QUERYCHANGE                                                                                                                                                                  |

## 41.6.2 CQ\_NOTIFICATION\$\_QUERY Object Type

The object type describes the changes to a query result caused by an event such as a transaction commit.

An array of `CQ_NOTIFICATION$_QUERY` descriptors is embedded inside the top level notification descriptor (`CQ_NOTIFICATION$_DESCRIPTOR`) for events of type `EVENT_QUERYCHANGE`. The array corresponds to the `SET` of queryids which were invalidated as a result of the event.

This is a synonym for the base type `SYS.CHNF$_QDESC`.

### Syntax

```
TYPE SYS.CHNF$_QDESC IS OBJECT (
    queryid            NUMBER,
```

```

queryop          NUMBER,
table_desc_array CQ_NOTIFICATION$_TABLE_ARRAY);

```

### Attributes

**Table 41-3 TYPE SYS.CQ\_NOTIFICATION\$\_QUERY Object Type**

| Attribute        | Description                                                             |
|------------------|-------------------------------------------------------------------------|
| queryid          | QueryId of the changed query                                            |
| queryop          | Operation describing change to the query                                |
| table_desc_array | Array of table changes which contributed to the query Result Set change |

## 41.6.3 CQ\_NOTIFICATION\$\_QUERY\_ARRAY Object (Array) Type

This type corresponds to an array of CQ\_NOTIFICATION\$\_QUERY objects. It is a synonym for the SYS.CHNF\$\_QUERY\_ARRAY type.

### Syntax

```
TYPE CQ_NOTIFICATION$_TABLE_ARRAY IS VARRAY (1073741824) OF CQ_NOTIFICATION$_TABLE;
```

## 41.6.4 CQ\_NOTIFICATION\$\_TABLE Object Type

This descriptor type describes a change to a table and is embedded inside the top level change notification descriptor type for EVENT\_OBJCHANGE event types. For query result set changes (event type will be set to EVENT\_QUERYCHANGE), the array of table descriptors is embedded inside each query change descriptor.

Note that this is a synonym for the type previously named SYS.CHNF\$\_TDESC.

### Syntax

```

TYPE SYS.CHNF$_TDESC IS OBJECT (
  opflags          NUMBER,
  table_name       VARCHAR2(2*M_IDEN+1),
  numrows         NUMBER,
  row_desc_array   CQ_NOTIFICATION$_ROW_ARRAY)

```

### Attributes

**Table 41-4 TYPE SYS.CQ\_NOTIFICATION\$\_TABLE Object Type**

| Attribute  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| opflags    | Table level operation flags. This is a flag field (bit-vector) that describes the operations that occurred on the table. It can be an OR of the following bit fields - INSERTOP, UPDATEOP, DELETEOP, DROPOP, ALTEROP, ALL_ROWS. If the ALL_ROWS (0x1) bit is set it means that either the entire table is modified (for example, DELETE * FROM t) or row level granularity of information is not requested or not available in the notification and the receiver has to conservatively assume that the entire table has been invalidated. |
| table_name | Name of modified table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 41-4 (Cont.) TYPE SYS.CQ\_NOTIFICATION\$\_TABLE Object Type**

| Attribute      | Description                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| numrows        | Number of modified rows within the table. numrows will be NULL and hence should not be accessed if the ALL_ROWS bit is set in the table change descriptor. |
| row_desc_array | Array of row descriptors. This field will be NULL if the ALL_ROWS bit is set in opflags.                                                                   |

## 41.6.5 CQ\_NOTIFICATION\$\_TABLE\_ARRAY Object (Array) Type

This type corresponds to an array of CQ\_NOTIFICATION\$\_TABLE objects. It is a synonym for the SYS.CHNF\$\_TDESC\_ARRAY type.

### Syntax

```
TYPE CQ_NOTIFICATION$_TABLE_ARRAY IS VARRAY (1073741824) OF CQ_NOTIFICATION$_TABLE;
```

## 41.6.6 CQ\_NOTIFICATION\$\_ROW Object Type

An array of CQ\_NOTIFICATION\$\_ROW is embedded inside a CQ\_NOTIFICATION\$\_TABLE (table change descriptor), if the QOS\_ROWIDS option was chosen at registration and the ALL\_ROWS bit is not set in the opflags field of the table change descriptor.

Note that this is a synonym for the type previously named SYS.CHNF\$\_RDESC.

### Syntax

```
TYPE SYS.CHNF$_RDESC IS OBJECT (
    opflags          NUMBER,
    row_id           VARCAHR2 (2000));
```

### Attributes

**Table 41-5 TYPE SYS.CQ\_NOTIFICATION\$\_ROW Object Type**

| Attribute | Description                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| opflags   | Row level operation flags. The flag field (bit vector) describes the operations in the row (could be INSERTOP, UPDATEOP or DELETEOP). |
| row_id    | The rowid of the modified row                                                                                                         |

## 41.6.7 CQ\_NOTIFICATION\$\_ROW\_ARRAY Object (Array) Type

This object type corresponds to an array of CQ\_NOTIFICATION\$\_ROW objects. It is embedded inside the CQ\_NOTIFICATION\$\_TABLE if QOS\_ROWIDS was specified during registration and the ALL\_ROWS bit is not set in the opflags field of the table change descriptor.

This type is a synonym for the SYS.CHNF\$\_RDESC\_ARRAY type.

**Syntax**

```
TYPE CQ_NOTIFICATION$_ROW_ARRAY IS VARRAY (1073741824) OF CQ_NOTIFICATION$_ROW;
```

## 41.6.8 CQ\_NOTIFICATION\$\_REG\_INFO Object Type

The object type describes the attributes associated with creating a new registration. It is a synonym for the type previously named SYS.CHNF\$\_REG\_INFO.

**Syntax**

```
TYPE SYS.CHNF$_REG_INFO IS OBJECT (
  callback                VARCHAR2 (20),
  qosflags                 NUMBER,
  timeout                 NUMBER,
  operations_filter       NUMBER,
  transaction_lag         NUMBER,
  ntfn_grouping_class     NUMBER,
  ntfn_grouping_value     NUMBER,
  ntfn_grouping_type      NUMBER,
  ntfn_grouping_start_time TIMESTAMP WITH TIME ZONE,
  ntfn_grouping_repeat_count NUMBER);
```

**Attributes****Table 41-6 TYPE CQ\_NOTIFICATION\$\_REG\_INFO Object Type**

| Attribute | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| callback  | Name of the server side PL/SQL procedure to be executed on a notification. Prototype is <call_backname>(ntfnds IN SYS.chnf\$_desc)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| qosflags  | <p>Quality of service flags. Can be set to an OR of the following values:</p> <ul style="list-style-type: none"> <li>QOS_RELIABLE (0x1): Notifications are reliable (persistent) and survive instance death. This means that on an instance death in an Oracle RAC cluster, surviving instances will be able to deliver any queued invalidations. Similarly, pending invalidations can be delivered on instance restart, in a single instance configuration. The disadvantage is that there is a CPU cost/ latency involved in inserting the invalidation message to a persistent store. If this parameter is false, then server side CPU and latency are minimized, because invalidations are buffered into an in memory queue but the client could lose invalidation messages on an instance shutdown.</li> <li>QOS_DEREG_NFY (0x2): The registration will be expunged on the first notification</li> <li>QOS_ROWIDS (0x4): The notification needs to include information about the rowids that were modified</li> <li>QOS_QUERY (0x8): specifies query result change notification as opposed to object change notification</li> <li>QOS_BEST_EFFORT (0x10) or QOS_BEST_EFFORT (0x16): can register simplified versions of queries and minimizes evaluation with some false positives.</li> </ul> |

Table 41-6 (Cont.) TYPE CQ\_NOTIFICATIONS\$ REG\_INFO Object Type

| Attribute                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeout                  | If set to a nonzero value, specifies the time in seconds after which the registration is automatically expunged by the database. If zero / NULL, the registration lives until explicitly deregistered. Note that the <code>timeout</code> option can be combined with the purge on notification (QOS_DEREG_NFY) option as well.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| operations_filter        | <p>if nonzero, specifies a filter to be selectively notified on certain operations. These flags can be used to filter based on specific operation types:</p> <ul style="list-style-type: none"> <li>• 0: Notify on all operations (DBMS_CQ_NOTIFICATION.ALL_OPERATIONS)</li> <li>• 0x2: Notify on every INSERT (DBMS_CQ_NOTIFICATION.INSERTOP)</li> <li>• 0x4: Notify on every UPDATE (DBMS_CQ_NOTIFICATION.UPDATEOP)</li> <li>• 0x8: Notify on every DELETE (DBMS_CQ_NOTIFICATION.DELETEOP)</li> </ul> <p>A combination of operations can be specified by using a bitwise OR.</p> <p>Caution: This parameter will be honored for object level registrations but ignored for query result change registrations. To implement notification flow control in 11g, the applications can use the "GROUPING notification" option.</p> |
| transaction_lag          | <p>Lag between consecutive notifications in units of transactions. Can be used to specify the number of transactions/database changes, by which the client is willing to lag behind the database. If 0, it means that the client needs to receive an invalidation message as soon as it is generated.</p> <p><b>Caution:</b> This parameter will be honored for object level registrations but ignored for query result change notification registrations.</p>                                                                                                                                                                                                                                                                                                                                                                  |
| ntfn_grouping_class      | When grouping notifications, the class based on which the group is derived. Currently, the only allowed value is DBMS_CQ_NOTIFICATION.NTFN_GROUPING_CLASS_TIME by which notifications are grouped by time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ntfn_grouping_value      | The grouping value. This describes the time interval that defines the group in seconds. For example, if this were set to 900, it would mean that notifications that were generated in each 15 minute interval would be grouped together.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ntfn_grouping_type       | <p>The type of grouping desired. It can be one of two allowed values</p> <ul style="list-style-type: none"> <li>• DBMS_CQ_NOTIFICATION.NTFN_GROUPING_TYPE_SUMMARY - all notifications in the group are summarized into a single notification</li> <li>• DBMS_CQ_NOTIFICATION.NTFN_GROUPING_TYPE_LAST - only the last notification in the group is published and the earlier ones discarded</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ntfn_grouping_start_time | When to start generating notifications. If specified as NULL, it defaults to the current system generated time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 41-6 (Cont.) TYPE CQ\_NOTIFICATION\$\_REG\_INFO Object Type**

| Attribute                  | Description                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ntfn_grouping_repeat_count | How many times the notification should be repeated. Set this to DBMS_CQ_NOTIFICATION.NTFN_GROUPING_FOREVER to receive notifications for the life time of the registration. Set to a nonzero value if only a certain number of notifications are desired for the life time of the registration. |

### Usage Notes

- The type declaration incorporates three other alternative constructors. In the first case all other parameters default to their default values.

```
TYPE CQ_NOTIFICATION$_REG_INFO IS OBJECT (
    callback          VARCHAR2(20),
    qosflags          NUMBER,
    timeout           NUMBER);
```

The second option applies to the type constructor defined in a previous release, and which is retained for backward compatibility:

```
TYPE CQ_NOTIFICATION$_REG_INFO IS OBJECT (
    callback          VARCHAR2(20),
    qosflags          NUMBER,
    timeout           NUMBER,
    operations_filter NUMBER,
    transaction_lag   NUMBER);
```

The third definition contains all the members of the type except `transaction_lag` which is being deprecated:

```
TYPE CQ_NOTIFICATION$_REG_INFO IS OBJECT (
    callback          VARCHAR2(20),
    qosflags          NUMBER,
    timeout           NUMBER,
    operations_filter NUMBER,
    ntfn_grouping_class NUMBER,
    ntfn_grouping_value NUMBER,
    ntfn_grouping_type NUMBER,
    ntfn_grouping_start_time TIMESTAMP WITH TIME ZONE,
    ntfn_grouping_repeat_count NUMBER);
```

- In response to a database change, the server side PL/SQL procedure specified by "callback" is executed. The PL/SQL procedure name has to be specified in the format `schema_name.procedure_name`. The procedure must have the following signature:

```
PROCEDURE <procedure_name>(ntfnds IN SYS.chnf$_desc)
```

`CHNF$_DESC` describes the change notification descriptor.

- The `init.ora` parameter `job_queue_processes` must be set to a nonzero value to receive PL/SQL notifications, because the specified procedure is executed inside a job queue process when a notification is generated.

## 41.7 Summary of DBMS\_CQ\_NOTIFICATION Subprograms

This table lists the DBMS\_CQ\_NOTIFICATION subprograms and briefly describes them.

**Table 41-7 DBMS\_CQ\_NOTIFICATION Package Subprograms**

| Subprogram                                       | Description                                                                                                                                |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CQ_NOTIFICATION_QUERYID Function</a> | Returns the queryid of the most recent query that was attempted to be registered in a registration block                                   |
| <a href="#">DEREGISTER Procedure</a>             | De-subscribes the client with the supplied registration identifier (ID)                                                                    |
| <a href="#">ENABLE_REG Procedure</a>             | Begins a registration block using an existing registration identifier (ID)                                                                 |
| <a href="#">NEW_REG_START Function</a>           | Begins a new registration block                                                                                                            |
| <a href="#">REG_END Procedure</a>                | Ends the registration boundary                                                                                                             |
| <a href="#">SET_ROWID_THRESHOLD Procedure</a>    | Configures the maximum number of rows of a table published in a change notification if the rows of the table are modified in a transaction |

### 41.7.1 CQ\_NOTIFICATION\_QUERYID Function

This function returns the queryid of the most recent query that was attempted to be registered in a registration block.

#### Syntax

```
DBMS_CQ_NOTIFICATION.CQ_NOTIFICATION_QUERYID  
RETURN NUMBER;
```

#### Return Values

Returns the queryid of the most recently registered query.

### 41.7.2 DEREGISTER Procedure

This procedure describes the client with the specified registration identifier (ID).

#### Syntax

```
DBMS_CQ_NOTIFICATION.DEREGISTER (  
    regid IN NUMBER);
```

#### Parameters

**Table 41-8 DEREGISTER Procedure Parameters**

| Parameter | Description            |
|-----------|------------------------|
| regid     | Client registration ID |

#### Usage Notes

Only the user that created the registration (or the SYS user) will be able to unsubscribe the registration.

## 41.7.3 ENABLE\_REG Procedure

This procedure adds objects to an existing registration identifier (ID).

It is similar to the interface for creating a new registration, except that it takes an existing `regid` to which to add objects. Subsequent execution of queries causes the objects referenced in the queries to be added to the specified `regid`, and the registration is completed on invoking the [REG\\_END Procedure](#).

### Syntax

```
DBMS_CQ_NOTIFICATION.ENABLE_REG (  
    regid IN NUMBER);
```

### Parameters

**Table 41-9** ENABLE\_REG Procedure Parameters

| Parameter          | Description            |
|--------------------|------------------------|
| <code>regid</code> | Client registration ID |

### Usage Notes

Only the user that created the registration will be able to add further objects to the registration.

## 41.7.4 NEW\_REG\_START Function

This procedure begins a new registration block.

Any objects referenced by queries executed within the registration block are considered interesting objects and added to the registration. The registration block ends upon calling the `REG_END` procedure.

### Syntax

```
DBMS_CQ_NOTIFICATION.NEW_REG_START (  
    regds IN sys.chnf$_reg_info)  
RETURN NUMBER;
```

### Parameters

**Table 41-10** NEW\_REG\_START Function Parameters

| Parameter                        | Description                                                                                          |
|----------------------------------|------------------------------------------------------------------------------------------------------|
| <code>sys.chnf\$_reg_info</code> | Registration descriptor describing the notification handler and other properties of the registration |

### Return Values

The procedure returns a registration-id which is a unique integer assigned by the database to this registration. The registration-id will be echoed back in every notification received for this registration.

### Usage Notes

- The only operations permitted inside a registration block are queries (the ones the user wishes to register). DML and DDL operations are not permitted.
- The registration block is a session property and implicitly terminates upon exiting the session. While the registration block is a session property, the registration itself is a persistent database entity. Once created, the registration survives until explicitly deregistered by the client application or timed-out or removed by the database for some other reason (such as loss of privileges).
- The user must have the `CHANGE_NOTIFICATION` system privilege and `SELECT` or `READ` privileges on any objects to be registered.
- The `SYS` user will not be permitted to create new registrations.
- Nesting of registration block is not permitted.

## 41.7.5 REG\_END Procedure

This procedure marks the end of the registration block. No newly executed queries are tracked.

### Syntax

```
DBMS_CQ_NOTIFICATION.REG_END;
```

## 41.7.6 SET\_ROWID\_THRESHOLD Procedure

This procedure configures the maximum number of rows of a table published in a change notification if the rows of the table are modified in a transaction.

### Syntax

```
DBMS_CQ_NOTIFICATION.SET_ROWID_THRESHOLD (
    tname      IN VARCHAR2,
    threshold  IN NUMBER);
```

### Parameters

**Table 41-11 SET\_ROWID\_THRESHOLD Procedure Parameters**

| Parameter | Description                                                                             |
|-----------|-----------------------------------------------------------------------------------------|
| tname     | Table name qualified by the schema name in the form <code>schemaname.tablename</code>   |
| threshold | Maximum number of modified rows of the table to be published in the change notification |

### Usage Notes

- The table needs to be registered for change notification either at object change granularity or at query result set granularity.
- The threshold set by means of this subprogram applies to that instance only and does not persist across instance startup/shutdown.

# DBMS\_CREDENTIAL

The `DBMS_CREDENTIAL` package provides an interface for authenticating and impersonating `EXTPROC` callout functions, as well as external jobs, remote jobs and file watchers from the `SCHEDULER`.

## See Also:

- *Oracle Database Administrator's Guide* regarding Specifying Job Credentials
- *Oracle Database Security Guide* regarding Guidelines for Securing External Processes

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Operational Notes](#)
- [Summary of DBMS\\_CREDENTIAL Subprograms](#)

## 42.1 DBMS\_CREDENTIAL Overview

Credentials are database objects that hold a username/password pair for authenticating and impersonating `EXTPROC` callout functions, as well as remote jobs, external jobs and file watchers from the `SCHEDULER`.

They are created using the [CREATE\\_CREDENTIAL Procedure](#). The procedure also allows you to specify the Windows domain for remote external jobs executed against a Windows server.

## 42.2 DBMS\_CREDENTIAL Security Model

Every Oracle credential has a unique credential name and you can associate a credential through its unique credential name with `EXTPROC` by means of a PL/SQL alias library.

In order to associate a credential with a PL/SQL alias library and external procedure, you must have the `CREATE AND/OR REPLACE LIBRARY` privilege or `CREATE AND/OR REPLACE FUNCTION / PROCEDURE` privilege and read permission of the DLL or shared object that the alias library to be associated with so that you can create and/or replace function or procedure to make use of the alias library.

Once authenticated, `EXTPROC` must act on behalf of the client based on client's identity defined in the supplied user credential. If not authenticated, `EXTPROC` must return an error message.

In order to create or alter a credential, you must have the `CREATE CREDENTIAL` privilege. If you are attempting to create or alter a credential in a schema other than your own, you must have the `CREATE ANY CREDENTIAL` privilege.

## 42.3 DBMS\_CREDENTIAL Operational Notes

As the existing `CREATE OR REPLACE LIBRARY` statement and `CREATE OR REPLACE FUNCTION/PROCEDURE` do not support a `CREDENTIAL` clause, this model requires syntax and semantic changes in `CREATE OR REPLACE LIBRARY` and `CREATE OR REPLACE FUNCTION/PROCEDURE` statement.

For example:

```
CREATE OR REPLACE LIBRARY test
  AS '$ORACLE_HOME/bin/test.so' CREDENTIAL ricky_cred;
CREATE OR REPLACE FUNCTION ftest1
  (x VARCHAR2, y BINARY_INTEGER)
RETURN BINARY_INTEGER
AS LANGUAGE C
LIBRARY test
NAME "negative"
PARAMETERS(x STRING, y INT);
```

The credential name defined in the `CREDENTIAL` clause is a name of a database object. Therefore, do not enclose the credential name with single or double quotes.

An example of a credential being used on an external job:

```
BEGIN
  DBMS_SCHEDULER.CREATE_JOB(
    job_name          => 'example_job',
    job_type          => 'EXECUTABLE',
    job_action        => '/bin/ls',
    credential_name    => 'ricky_cred');
END;
/
```

## 42.4 Summary of DBMS\_CREDENTIAL Subprograms

This table lists the `DBMS_CREDENTIAL` subprograms and briefly describes them.

**Table 42-1 DBMS\_CREDENTIAL Package Subprograms**

| Subprogram                                   | Description                                                                              |
|----------------------------------------------|------------------------------------------------------------------------------------------|
| <a href="#">CREATE_CREDENTIAL Procedure</a>  | Creates a stored username/password pair in a database object called an Oracle credential |
| <a href="#">DISABLE_CREDENTIAL Procedure</a> | Disables an Oracle credential                                                            |
| <a href="#">DROP_CREDENTIAL Procedure</a>    | Drops an Oracle credential                                                               |
| <a href="#">ENABLE_CREDENTIAL Procedure</a>  | Enables an Oracle credential                                                             |
| <a href="#">UPDATE_CREDENTIAL Procedure</a>  | Updates an existing Oracle credential                                                    |

## 42.4.1 CREATE\_CREDENTIAL Procedure

This procedure creates a stored username/password pair in a database object called an Oracle credential. You can also use this procedure to manage the credentials used for accessing files stored in cloud object storage.

### Syntax

```
DBMS_CREDENTIAL.CREATE_CREDENTIAL (  
    credential_name    IN    VARCHAR2,  
    username           IN    VARCHAR2,  
    password           IN    VARCHAR2,  
    database_role       IN    VARCHAR2 DEFAULT NULL,  
    windows_domain     IN    VARCHAR2 DEFAULT NULL,  
    comments           IN    VARCHAR2 DEFAULT NULL,  
    enabled            IN    BOOLEAN DEFAULT TRUE);
```

### Parameters

**Table 42-2** *CREATE\_CREDENTIAL Procedure Parameters*

| Parameter       | Description                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| credential_name | Name of the credential. It can optionally be prefixed with a schema. This cannot be set to <code>NULL</code> . It is converted to upper case unless enclosed in double quotes.                              |
| username        | User name to login to the operating system or remote database to run a job if this credential is chosen. This cannot be set to <code>NULL</code> .                                                          |
| password        | Password to login to the remote operating system to run a job if this credential is chosen. It is case sensitive.                                                                                           |
| database_role   | Whether a database job using this credential should attempt to log in with administrative privileges. Values: <code>SYSDBA</code> , <code>SYSDBG</code> , <code>SYSADMIN</code> or <code>SYSBACKUP</code> . |
| windows_domain  | For a Windows remote executable target, this is the domain that the specified user belongs to. The domain will be converted to uppercase automatically.                                                     |
| comments        | A text string that can be used to describe the credential to the user. The Scheduler does not use this field.                                                                                               |
| enabled         | Determines whether the credential is enabled or not                                                                                                                                                         |

### Usage Notes

- Credentials reside in a particular schema and can be created by any user with the `CREATE CREDENTIAL` or `CREATE ANY CREDENTIAL` system privilege. To create a credential in a schema other than your own, you must have the `CREATE CREDENTIAL` or `CREATE ANY CREDENTIAL` privilege.
- The user name is case sensitive. It cannot contain double quotes or spaces.
- Attempting to create a credential with an existing credential name returns an error. To alter an existing credential, users must drop the existing credential first using the [DROP\\_CREDENTIAL Procedure](#).
- Attempting to drop an existing credential, which is already referenced by alias libraries, returns an error. To drop an existing credential without any checking, users must set the `force` parameter of [DROP\\_CREDENTIAL Procedure](#) to `TRUE`.

- You may also alter a credential, by means of the [UPDATE\\_CREDENTIAL Procedure](#).

## Examples

### Create a Basic Credential

```
CONN scott
Enter password: password

BEGIN
-- Basic credential.
  DBMS_CREDENTIAL.CREATE_CREDENTIAL(
    credential_name => 'JAMES_SMITH',
    username        => 'james_smith',
    password        => 'password');
END
```

### Create a Windows Credential

```
CONN scott
Enter password: password

-- Credential including Windows domain
BEGIN
  DBMS_CREDENTIAL.CREATE_CREDENTIAL(
    credential_name => 'JAMES_SMITH_WIN_CREDENTIAL',
    username        => 'james_smith',
    password        => 'password',
    windows_domain  => 'localdomain');
END
```

### Display Information about Credentials

Information about credentials is displayed using the [DBA|ALL|USER] \_CREDENTIALS views.

```
COLUMN credential_name FORMAT A25
COLUMN username FORMAT A20
COLUMN windows_domain FORMAT A20
SELECT credential_name,
       username,
       windows_domain
FROM   user_credentials
ORDER BY credential_name;
```

| CREDENTIAL_NAME            | USERNAME    | WINDOWS_DOMAIN |
|----------------------------|-------------|----------------|
| JAMES_SMITH_CREDENTIAL     | james_smith |                |
| JAMES_SMITH_WIN_CREDENTIAL | james_smith | LOCALDOMAIN    |

2 rows selected.

## 42.4.2 DISABLE\_CREDENTIAL Procedure

This procedure disables an Oracle credential.

### Syntax

```
DBMS_CREDENTIAL.DISABLE_CREDENTIAL (
  credential_name IN VARCHAR2,
  force           IN BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 42-3** *DISABLE\_CREDENTIAL Procedure Parameters*

| Parameter       | Description                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| credential_name | Name of the credential. It can optionally be prefixed with a schema. This cannot be set to NULL. It is converted to upper case unless enclosed in double quotes.                                                                                                                            |
| force           | If FALSE, the credential is not disabled provided it has no dependency on any existing scheduler job or PL/SQL library. An error is returned if the dependency is observed. If TRUE, the credential is disabled whether or not there is any scheduler job or PL/SQL library referencing it. |

## Usage Notes

- Credentials reside in a particular schema and can be disabled by any user with the `CREATE CREDENTIAL` or `CREATE ANY CREDENTIAL` system privilege. To disable a credential in a schema other than your own, you must have the `CREATE ANY CREDENTIAL` privilege.
- A credential for an OS user can be viewed as an entry point into an operating system as a particular user. Allowing a credential to be disabled lets an administrator (or credential owner) to quickly, easily and reversibly disallow all logins from the database to the OS as a particular user of external jobs, database jobs, file transfers, external procedures, and file watching. To enable an existing disabled credential, you need to use the [ENABLE\\_CREDENTIAL Procedure](#).
- A library can become invalid if the properties of the credential – windows domain, username, password, its enable/disable bit – are changed.

## 42.4.3 DROP\_CREDENTIAL Procedure

This procedure drops an Oracle credential.

### Syntax

```
DBMS_CREDENTIAL.DROP_CREDENTIAL (  
    credential_name  IN  VARCHAR2,  
    force            IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 42-4** *DROP\_CREDENTIAL Procedure Parameters*

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| credential_name | Name of the credential. It can optionally be prefixed with a schema. This cannot be set to NULL.                                                                                                                                                                                                                                           |
| force           | If set to FALSE, the credential must not be referenced by any <code>EXTPROC</code> alias library or an error is raised. If set to TRUE, the credential is dropped whether or not there are <code>extproc</code> alias libraries referencing it. <code>EXTPROC</code> alias libraries that reference the dropped credential become invalid. |

### Usage Notes

Only the owner of a credential or a user with the `CREATE ANY CREDENTIAL` system privilege may drop the credential.

### Examples

```
EXEC DBMS_CREDENTIAL.DROP_CREDENTIAL('JAMES_SMITH_CREDENTIAL', FALSE);  
EXEC DBMS_CREDENTIAL.DROP_CREDENTIAL('JAMES_SMITH_WIN_CREDENTIAL', FALSE);
```

## 42.4.4 ENABLE\_CREDENTIAL Procedure

This procedure enables an Oracle credential.

### Syntax

```
DBMS_CREDENTIAL.ENABLE_CREDENTIAL (  
    credential_name  IN  VARCHAR2);
```

### Parameters

**Table 42-5** *ENABLE\_CREDENTIAL Procedure Parameters*

| Parameter       | Description                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| credential_name | Name of the credential. It can optionally be prefixed with a schema. This cannot be set to <code>NULL</code> . It is converted to upper case unless enclosed in double quotes. |

### Usage Notes

- Credentials reside in a particular schema and can be disabled by any user with the `CREATE CREDENTIAL` OR `CREATE ANY CREDENTIAL` system privilege. To disable a credential in a schema other than your own, you must have the `CREATE CREDENTIAL` OR `CREATE ANY CREDENTIAL` privilege.
- A credential for an OS user can be viewed as an entry point into an operating system as a particular user. Allowing a credential to be disabled would allow an administrator (or credential owner) to quickly, easily and reversibly disallow all logins from the database to the OS as a particular user (external jobs, file transfers, external procedures, file watching). To disable an existing credential, you need to use the [DISABLE\\_CREDENTIAL Procedure](#).
- A library can become invalid if the properties of the credential – windows domain, username, password, its enable/disable bit – are changed.

## 42.4.5 UPDATE\_CREDENTIAL Procedure

This procedure updates an existing Oracle credential.

### Syntax

```
DBMS_CREDENTIAL.UPDATE_CREDENTIAL (  
    credential_name  IN  VARCHAR2,  
    attribute        IN  VARCHAR2,  
    value            IN  VARCHAR2);
```

## Parameters

**Table 42-6** *UPDATE\_CREDENTIAL Procedure Parameters*

| Parameter       | Description                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| credential_name | Name of the credential. It can optionally be prefixed with a schema. This cannot be set to NULL. It is converted to upper case unless enclosed in double quotation marks. |
| attribute       | Name of attribute to update: USERNAME, PASSWORD, WINDOWS_DOMAIN, DATABASE_ROLE or COMMENTS                                                                                |
| value           | New value for the selected attribute                                                                                                                                      |

## Usage Notes

- Credentials reside in a particular schema and can be created by any user with the `CREATE CREDENTIAL` or `CREATE ANY CREDENTIAL` system privilege. To create a credential in a schema other than your own, you must have the `CREATE ANY CREDENTIAL` privilege.
- The user name is case sensitive. It cannot contain double quotes or spaces.
- `EXTPROC` alias libraries that reference the updated credential will become invalid. A library becomes invalid if the properties of the credential – windows domain, username, password, its enable/disable bit – are changed.

## Examples

### Update a Basic Credential

```
CONN scott
Enter password: password

BEGIN
-- Basic credential.
  DBMS_CREDENTIAL.UPDATE_CREDENTIAL (
    credential_name => 'JAMES_SMITH_CREDENTIAL',
    attribute       => 'password',
    value          => 'password2');

  DBMS_CREDENTIAL.UPDATE_CREDENTIAL (
    credential_name => 'JAMES_SMITH_CREDENTIAL',
    attribute       => 'username',
    value          => 'james_smith');
END;
```

### Update a Windows Credential

```
CONN scott
Enter password: password

-- Credential including Windows domain
BEGIN
  DBMS_CREDENTIAL.UPDATE_CREDENTIAL(
    credential_name => 'JAMES_SMITH_WIN_CREDENTIAL',
    username       => 'james_smith',
    password       => 'password',
    windows_domain => 'localdomain');
END
```

## Display Information about Credentials

Information about credentials is displayed using the [DBA|ALL|USER] \_CREDENTIALS views.

```
COLUMN credential_name FORMAT A25
COLUMN username FORMAT A20
COLUMN windows_domain FORMAT A20
SELECT credential_name,
       username,
       windows_domain
FROM   all_credentials
ORDER BY credential_name;
```

| CREDENTIAL_NAME            | USERNAME    | WINDOWS_DOMAIN |
|----------------------------|-------------|----------------|
| JAMES_SMITH_CREDENTIAL     | james_smith |                |
| JAMES_SMITH_WIN_CREDENTIAL | james_smith | LOCALDOMAIN    |

# DBMS\_CRYPTO

`DBMS_CRYPTO` provides an interface to encrypt and decrypt stored data, and can be used in conjunction with PL/SQL programs running network communications. It provides support for several industry-standard encryption and hashing algorithms, including the Advanced Encryption Standard (AES) encryption algorithm. AES has been approved by the National Institute of Standards and Technology (NIST) to replace the Data Encryption Standard (DES).

## See Also:

*Oracle Database Security Guide* for further information about using this package and about encrypting data in general.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Datatypes](#)
- [Algorithms](#)
- [Restrictions](#)
- [Exceptions](#)
- [Operational Notes](#)
- [Summary of DBMS\\_CRYPTO Subprograms](#)

## 43.1 DBMS\_CRYPTO Overview

`DBMS_CRYPTO` contains basic cryptographic functions and procedures. To use this package correctly and securely, a general level of security expertise is assumed.

The `DBMS_CRYPTO` package enables encryption and decryption for common Oracle datatypes, including `RAW` and large objects (`LOBs`), such as images and sound. Specifically, it supports `BLOBS` and `CLOBs`. In addition, it provides Globalization Support for encrypting data across different database character sets.

The following cryptographic algorithms are supported:

- Data Encryption Standard (DES), Triple DES (3DES, 2-key and 3-key)
- Advanced Encryption Standard (AES)
- MD5, MD4, SHA-1, and SHA-2 cryptographic hashes
- MD5, SHA-1, and SHA-2 Message Authentication Code (MAC)

Block cipher modifiers are also provided with `DBMS_CRYPTO`. You can choose from several padding options, including PKCS (Public Key Cryptographic Standard) #5, and from four block cipher chaining modes, including Cipher Block Chaining (CBC).

Table 43-1 summarizes the DBMS\_CRYPTO package features.

**Table 43-1 DBMS\_CRYPTO Features**

| Package Feature                              | DBMS_CRYPTO                                            |
|----------------------------------------------|--------------------------------------------------------|
| Cryptographic algorithms                     | DES, 3DES, AES, RC4, 3DES_2KEY                         |
| Padding forms                                | PKCS5, zeroes                                          |
| Block cipher chaining modes                  | CBC, CFB, ECB, OFB                                     |
| Cryptographic hash algorithms                | MD5, SHA-1, SHA-2 (SHA-256, SHA-384, SHA-512), MD4     |
| Keyed hash (MAC) algorithms                  | HMAC_MD5, HMAC_SH1, HMAC_SH256, HMAC_SH384, HMAC_SH512 |
| Cryptographic pseudo-random number generator | RAW, NUMBER, BINARY_INTEGER                            |
| Database types                               | RAW, CLOB, BLOB                                        |

The DBMS\_CRYPTO package replaces DBMS\_OBFUSCATION\_TOOLKIT, providing greater ease of use and support for a range of algorithms to accommodate new and existing systems. Specifically, 3DES\_2KEY and MD4 are provided for backward compatibility. It is not recommended that you use these algorithms because they do not provide the same level of security as provided by 3DES, AES, MD5, SHA-1, or SHA-2.

## 43.2 DBMS\_CRYPTO Security Model

Oracle Database installs this package in the SYS schema. You can then grant package access to existing users and roles as needed.

## 43.3 DBMS\_CRYPTO Datatypes

Parameters for the DBMS\_CRYPTO subprograms use these datatypes.

**Table 43-2 DBMS\_CRYPTO Datatypes**

| Type        | Description                                                                        |
|-------------|------------------------------------------------------------------------------------|
| BLOB        | A source or destination binary LOB                                                 |
| CLOB        | A source or destination character LOB (excluding NCLOB)                            |
| PLS_INTEGER | Specifies a cryptographic algorithm type (used with BLOB, CLOB, and RAW datatypes) |
| RAW         | A source or destination RAW buffer                                                 |

## 43.4 DBMS\_CRYPTO Algorithms

The DBMS\_CRYPTO package contains predefined cryptographic algorithms, modifiers, and cipher suites.

These are shown in the following tables.

**Table 43-3 DBMS\_CRYPTO Cryptographic Hash Functions**

| Name       | Description                                                     |
|------------|-----------------------------------------------------------------|
| HASH_MD4   | Produces a 128-bit hash, or message digest of the input message |
| HASH_MD5   | Also produces a 128-bit hash, but is more complex than MD4      |
| HASH_SH1   | Secure Hash Algorithm (SHA-1). Produces a 160-bit hash.         |
| HASH_SH256 | SHA-2, produces a 256-bit hash.                                 |
| HASH_SH384 | SHA-2, produces a 384-bit hash.                                 |
| HASH_SH512 | SHA-2, produces a 512-bit hash.                                 |

**Table 43-4 DBMS\_CRYPTO MAC (Message Authentication Code) Functions**

| Name                  | Description                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------|
| HMAC_MD5 <sup>1</sup> | Same as MD5 hash function, except it requires a secret key to verify the hash value.           |
| HMAC_SH1 <sup>1</sup> | Same as SHA hash function, except it requires a secret key to verify the hash value.           |
| HMAC_SH256            | Same as SHA-2 256-bit hash function, except it requires a secret key to verify the hash value. |
| HMAC_SH384            | Same as SHA-2 384-bit hash function, except it requires a secret key to verify the hash value. |
| HMAC_SH512            | Same as SHA-2 512-bit hash function, except it requires a secret key to verify the hash value. |

<sup>1</sup> Complies with IETF RFC 2104 standard

**Table 43-5 DBMS\_CRYPTO Encryption Algorithms**

| Name              | Description                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------|
| ENCRYPT_DES       | Data Encryption Standard. Block cipher. Uses key length of 56 bits.                                                |
| ENCRYPT_3DES_2KEY | Data Encryption Standard. Block cipher. Operates on a block 3 times with 2 keys. Effective key length of 112 bits. |
| ENCRYPT_3DES      | Data Encryption Standard. Block cipher. Operates on a block 3 times.                                               |
| ENCRYPT_AES128    | Advanced Encryption Standard. Block cipher. Uses 128-bit key size.                                                 |
| ENCRYPT_AES192    | Advanced Encryption Standard. Block cipher. Uses 192-bit key size.                                                 |
| ENCRYPT_AES256    | Advanced Encryption Standard. Block cipher. Uses 256-bit key size.                                                 |
| ENCRYPT_RC4       | Stream cipher. Uses a secret, randomly generated key unique to each session.                                       |

**Table 43-6 DBMS\_CRYPTO Block Cipher Suites**

| Name           | Description                                                                 |
|----------------|-----------------------------------------------------------------------------|
| DES_CBC_PKCS5  | ENCRYPT_DES <sup>1</sup> + CHAIN_CBC <sup>2</sup> + PAD_PKCS5 <sup>3</sup>  |
| DES3_CBC_PKCS5 | ENCRYPT_3DES <sup>1</sup> + CHAIN_CBC <sup>2</sup> + PAD_PKCS5 <sup>3</sup> |

<sup>1</sup> See [Table 43-5](#)

<sup>2</sup> See [Table 43-7](#)

<sup>3</sup> See [Table 43-8](#)

**Table 43-7 DBMS\_CRYPTO Block Cipher Chaining Modifiers**

| Name      | Description                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHAIN_ECB | Electronic Codebook. Encrypts each plaintext block independently.                                                                                                                                                                         |
| CHAIN_CBC | Cipher Block Chaining. Plaintext is XORed with the previous ciphertext block before it is encrypted.                                                                                                                                      |
| CHAIN_CFB | Cipher-Feedback. Enables encrypting units of data smaller than the block size.                                                                                                                                                            |
| CHAIN_OFB | Output-Feedback. Enables running a block cipher as a synchronous stream cipher. Similar to CFB, except that <i>n</i> bits of the previous output block are moved into the right-most positions of the data queue waiting to be encrypted. |

**Table 43-8 DBMS\_CRYPTO Block Cipher Padding Modifiers**

| Name      | Description                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| PAD_PKCS5 | Provides padding which complies with the PKCS #5: Password-Based Cryptography Standard                                  |
| PAD_NONE  | Provides option to specify no padding. Caller must ensure that blocksize is correct, else the package returns an error. |
| PAD_ZERO  | Provides padding consisting of zeroes                                                                                   |

## 43.5 DBMS\_CRYPTO Restrictions

The `VARCHAR2` datatype is not directly supported by `DBMS_CRYPTO`. Before you can perform cryptographic operations on data of the type `VARCHAR2`, you must convert it to the uniform database character set `AL32UTF8`, and then convert it to the `RAW` datatype. After performing these conversions, you can then encrypt it with the `DBMS_CRYPTO` package.

### See Also:

[DBMS\\_CRYPTO Operational Notes](#) for information about the conversion rules for converting datatypes.

## 43.6 DBMS\_CRYPTO Exceptions

The following table lists exceptions that have been defined for `DBMS_CRYPTO`.

**Table 43-9 DBMS\_CRYPTO Exceptions**

| Exception                       | Code  | Description                                                                      |
|---------------------------------|-------|----------------------------------------------------------------------------------|
| <code>CipherSuiteInvalid</code> | 28827 | The specified cipher suite is not defined.                                       |
| <code>CipherSuiteNull</code>    | 28829 | No value has been specified for the cipher suite to be used.                     |
| <code>KeyNull</code>            | 28239 | The encryption key has not been specified or contains a <code>NULL</code> value. |

**Table 43-9 (Cont.) DBMS\_CRYPTO Exceptions**

| Exception        | Code  | Description                                                                                                                                                                                 |
|------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KeyBadSize       | 28234 | DES keys: Specified key size is too short. DES keys must be at least 8 bytes (64 bits).<br>AES keys: Specified key size is not supported. AES keys must be 128, 192, or 256 bits in length. |
| DoubleEncryption | 28233 | Source data was previously encrypted.                                                                                                                                                       |

## 43.7 DBMS\_CRYPTO Operational Notes

This section describes several DBMS\_CRYPTO operational notes.

- When to Use Encrypt and Decrypt Procedures or Functions
- When to Use Hash or Message Authentication Code (MAC) Functions
- About Generating and Storing Encryption Keys
- Conversion Rules

### When to Use Encrypt and Decrypt Procedures or Functions

This package includes both `ENCRYPT` and `DECRYPT` procedures and functions. The procedures are used to encrypt or decrypt `LOB` datatypes (overloaded for `CLOB` and `BLOB` datatypes). In contrast, the `ENCRYPT` and `DECRYPT` functions are used to encrypt and decrypt `RAW` datatypes. Data of type `VARCHAR2` must be converted to `RAW` before you can use `DBMS_CRYPTO` functions to encrypt it.

### When to Use Hash or Message Authentication Code (MAC) Functions

This package includes two different types of one-way hash functions: the `HASH` function and the `MAC` function. Hash functions operate on an arbitrary-length input message, and return a fixed-length hash value. One-way hash functions work in one direction only. It is easy to compute a hash value from an input message, but it is extremely difficult to generate an input message that hashes to a particular value. Note that hash values should be at least 128 bits in length to be considered secure.

You can use hash values to verify whether data has been altered. For example, before storing data, the user runs `DBMS_CRYPTO.HASH` against the stored data to create a hash value. On returning the stored data, the user can again run the hash function against it, using the same algorithm. If the second hash value is identical to the first one, then the data has not been altered. Hash values are similar to "file fingerprints" and are used to ensure data integrity.

The `HASH` function included with `DBMS_CRYPTO`, is a one-way hash function that you can use to generate a hash value from either `RAW` or `LOB` data. The `MAC` function is also a one-way hash function, but with the addition of a secret key. It works the same way as the `DBMS_CRYPTO.HASH` function, except only someone with the key can verify the hash value.

MACs can be used to authenticate files between users. They can also be used by a single user to determine if her files have been altered, perhaps by a virus. A user could compute the MAC of his files and store that value in a table. If the user did not use a MAC function, then the virus could compute the new hash value after infection and replace the table entry. A virus cannot do that with a MAC because the virus does not know the key.

## About Generating and Storing Encryption Keys

The `DBMS_CRYPTO` package can generate random material for encryption keys, but it does not provide a mechanism for maintaining them. Application developers must take care to ensure that the encryption keys used with this package are securely generated and stored. Also note that the encryption and decryption operations performed by `DBMS_CRYPTO` occur on the server, not on the client. Consequently, if the key is sent over the connection between the client and the server, the connection must be protected by using network encryption. Otherwise, the key is vulnerable to capture over the wire.

Although `DBMS_CRYPTO` cannot generate keys on its own, it does provide tools you can use to aid in key generation. For example, you can use the `RANDOMBYTES` function to generate random material for keys.

When generating encryption keys for DES, it is important to remember that some numbers are considered weak and semiweak keys. Keys are considered weak or semiweak when the pattern of the algorithm combines with the pattern of the initial key value to produce ciphertext that is more susceptible to cryptanalysis. To avoid this, filter out the known weak DES keys. Lists of the known weak and semiweak DES keys are available on several public Internet sites.

- [RANDOMBYTES Function](#)

## Conversion Rules

- To convert `VARCHAR2` to `RAW`, use the `UTL_I18N.STRING_TO_RAW` function to perform the following steps:
  1. Convert `VARCHAR2` in the current database character set to `VARCHAR2` in the `AL32UTF8` database character.
  2. Convert `VARCHAR2` in the `AL32UTF8` database character set to `RAW`.

Syntax example:

```
UTL_I18N.STRING_TO_RAW (string, 'AL32UTF8');
```

- To convert `RAW` to `VARCHAR2`, use the `UTL_I18N.RAW_TO_CHAR` function to perform the following steps:
  1. Convert `RAW` to `VARCHAR2` in the `AL32UTF8` database character set.
  2. Convert `VARCHAR2` in the `AL32UTF8` database character set to `VARCHAR2` in the database character set you wish to use.

Syntax example:

```
UTL_I18N.RAW_TO_CHAR (data, 'AL32UTF8');
```

 See Also:

[UTL\\_I18N](#) for information about using the UTL\_I18N PL/SQL package.

- If you want to store encrypted data of the RAW datatype in a VARCHAR2 database column, then use RAWTOHEX or UTL\_ENCODE.BASE64\_ENCODE to make it suitable for VARCHAR2 storage. These functions expand data size by 2 and 4/3, respectively.

## 43.8 DBMS\_CRYPTO Examples

This listing shows PL/SQL block encrypting and decrypting pre-defined 'input\_string' using 256-bit AES algorithm with Cipher Block Chaining and PKCS#5 compliant padding.

```
DECLARE
    input_string      VARCHAR2 (200) := 'Secret Message';
    output_string     VARCHAR2 (200);
    encrypted_raw     RAW (2000);      -- stores encrypted binary text
    decrypted_raw     RAW (2000);      -- stores decrypted binary text
    num_key_bytes     NUMBER := 256/8; -- key length 256 bits (32 bytes)
    key_bytes_raw     RAW (32);        -- stores 256-bit encryption key
    encryption_type   PLS_INTEGER :=  -- total encryption type

        DBMS_CRYPTO.ENCRYPT_AES256
        + DBMS_CRYPTO.CHAIN_CBC
        + DBMS_CRYPTO.PAD_PKCS5;

    iv_raw            RAW (16);

BEGIN
    DBMS_OUTPUT.PUT_LINE ( 'Original string: ' || input_string);
    key_bytes_raw := DBMS_CRYPTO.RANDOMBYTES (num_key_bytes);
    iv_raw        := DBMS_CRYPTO.RANDOMBYTES (16);
    encrypted_raw := DBMS_CRYPTO.ENCRYPT
    (
        src => UTL_I18N.STRING_TO_RAW (input_string, 'AL32UTF8'),
        typ => encryption_type,
        key => key_bytes_raw,
        iv  => iv_raw
    );

    -- The encrypted value "encrypted_raw" can be used here

    decrypted_raw := DBMS_CRYPTO.DECRYPT
    (
        src => encrypted_raw,
        typ => encryption_type,
        key => key_bytes_raw,
        iv  => iv_raw
    );

    output_string := UTL_I18N.RAW_TO_CHAR (decrypted_raw, 'AL32UTF8');

    DBMS_OUTPUT.PUT_LINE ('Decrypted string: ' || output_string);
END;
```

## 43.9 Summary of DBMS\_CRYPTO Subprograms

This table lists the DBMS\_CRYPTO subprograms in alphabetical order and briefly describes them.

**Table 43-10 DBMS\_CRYPTO Package Subprograms**

| Subprogram                             | Description                                                                                                                                                |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DECRYPT Function</a>       | Decrypts RAW data using a stream or block cipher with a user supplied key and optional IV (initialization vector)                                          |
| <a href="#">DECRYPT Procedures</a>     | Decrypts LOB data using a stream or block cipher with a user supplied key and optional IV                                                                  |
| <a href="#">ENCRYPT Function</a>       | Encrypts RAW data using a stream or block cipher with a user supplied key and optional IV                                                                  |
| <a href="#">ENCRYPT Procedures</a>     | Encrypts LOB data using a stream or block cipher with a user supplied key and optional IV                                                                  |
| <a href="#">HASH Function</a>          | Applies one of the supported cryptographic hash algorithms (MD4, MD5, SHA-1, or SHA-2) to data                                                             |
| <a href="#">MAC Function</a>           | Applies Message Authentication Code algorithms (MD5, SHA-1, or SHA-2) to data to provide keyed message protection                                          |
| <a href="#">RANDOMBYTES Function</a>   | Returns a RAW value containing a cryptographically secure pseudo-random sequence of bytes, and can be used to generate random material for encryption keys |
| <a href="#">PKDECRYPT Function</a>     | Decrypts RAW data using a private key assisted with key algorithm and encryption algorithm and returns decrypted data.                                     |
| <a href="#">PKENCRYPT Function</a>     | Encrypts RAW data using a public key assisted with key algorithm and encryption algorithm and returns encrypted data                                       |
| <a href="#">RANDOMINTEGER Function</a> | Returns a random BINARY_INTEGER                                                                                                                            |
| <a href="#">RANDOMNUMBER Function</a>  | Returns a random 128-bit integer of the NUMBER datatype                                                                                                    |
| <a href="#">SIGN Function</a>          | Signs RAW data using a private key assisted with key algorithm and sign algorithm, and returns a signature                                                 |
| <a href="#">VERIFY Function</a>        | Verifies RAW data using the signature, public key assisted with key algorithm, and sign algorithm. It returns TRUE if the signature was verified           |

### 43.9.1 DECRYPT Function

This function decrypts RAW data using a stream or block cipher with a user supplied key and optional IV (initialization vector).

#### Syntax

```
DBMS_CRYPTO.DECRYPT (
    src IN RAW,
    typ IN PLS_INTEGER,
    key IN RAW,
    iv IN RAW DEFAULT NULL)
RETURN RAW;
```

## Pragmas

```
pragma restrict_references (decrypt, WNDS, RNDS, WNPS, RNPS);
```

## Parameters

**Table 43-11** DECRYPT Function Parameters

| Parameter Name | Description                                                        |
|----------------|--------------------------------------------------------------------|
| src            | RAW data to be decrypted.                                          |
| typ            | Stream or block cipher type and modifiers to be used.              |
| key            | Key to be used for decryption.                                     |
| iv             | Optional initialization vector for block ciphers. Default is NULL. |

## Usage Notes

- To retrieve original plaintext data, `DECRYPT` must be called with the same cipher, modifiers, key, and IV that was used to encrypt the data originally.

### See Also:

"[Usage Notes](#)" for the `ENCRYPT` function for additional information about the ciphers and modifiers available with this package.

- If `VARCHAR2` data is converted to `RAW` before encryption, then it must be converted back to the appropriate database character set by using the `UTL_I18N` package.

### See Also:

[DBMS\\_CRYPTO Operational Notes](#) for a discussion of the `VARCHAR2` to `RAW` conversion rules

## 43.9.2 DECRYPT Procedures

These procedures decrypt `LOB` data using a stream or block cipher with a user supplied key and optional IV (initialization vector).

### Syntax

```
DBMS_CRYPTO.DECRYPT (
  dst IN OUT NOCOPY BLOB,
  src IN              BLOB,
  typ IN              PLS_INTEGER,
  key IN              RAW,
  iv IN              RAW          DEFAULT NULL);

DBMS_CRYPT.DECRYPT (
  dst IN OUT NOCOPY CLOB          CHARACTER SET ANY_CS,
  src IN              BLOB,
  typ IN              PLS_INTEGER,
```

```
key IN          RAW,  
iv  IN          RAW          DEFAULT NULL);
```

### Pragmas

```
pragma restrict_references(decrypt,WNDS,RNDS,WNPS,RNPS);
```

### Parameters

**Table 43-12 DECRYPT Procedure Parameters**

| Parameter Name | Description                                                                        |
|----------------|------------------------------------------------------------------------------------|
| dst            | LOB locator of output data. The value in the output LOB <dst> will be overwritten. |
| src            | LOB locator of input data.                                                         |
| typ            | Stream or block cipher type and modifiers to be used.                              |
| key            | Key to be used for decryption.                                                     |
| iv             | Optional initialization vector for block ciphers. Default is all zeroes.           |

## 43.9.3 ENCRYPT Function

This function encrypts RAW data using a stream or block cipher with a user supplied key and optional IV (initialization vector).

### Syntax

```
DBMS_CRYPTO.ENCRYPT(  
  src IN RAW,  
  typ IN PLS_INTEGER,  
  key IN RAW,  
  iv  IN RAW          DEFAULT NULL)  
RETURN RAW;
```

### Pragmas

```
pragma restrict_references(encrypt,WNDS,RNDS,WNPS,RNPS);
```

### Parameters

**Table 43-13 ENCRYPT Function Parameters**

| Parameter Name | Description                                                        |
|----------------|--------------------------------------------------------------------|
| src            | RAW data to be encrypted.                                          |
| typ            | Stream or block cipher type and modifiers to be used.              |
| key            | Encryption key to be used for encrypting data.                     |
| iv             | Optional initialization vector for block ciphers. Default is NULL. |

### Usage Notes

- Block ciphers may be modified with chaining and padding type modifiers. The chaining and padding type modifiers are added to the block cipher to produce a cipher suite. Cipher Block Chaining (CBC) is the most commonly used chaining type, and PKCS #5 is the

recommended padding type. See [Table 43-7](#) and [Table 43-8](#) for block cipher chaining and padding modifier constants that have been defined for this package.

- To improve readability, you can define your own package-level constants to represent the cipher suites you use for encryption and decryption. For example, the following example defines a cipher suite that uses DES, cipher block chaining mode, and no padding:

```
DES_CBC_NONE CONSTANT PLS_INTEGER := DBMS_CRYPTO.ENCRYPT_DES
                                     + DBMS_CRYPTO.CHAIN_CBC
                                     + DBMS_CRYPTO.PAD_NONE;
```

See [Table 43-6](#) for the block cipher suites already defined as constants for this package.

- To encrypt VARCHAR2 data, it should first be converted to the AL32UTF8 character set.

#### See Also:

The discussion of conversion rules under [DBMS\\_CRYPTO Operational Notes](#)

- Stream ciphers, such as RC4, are not recommended for stored data encryption.

## 43.9.4 ENCRYPT Procedures

These procedures encrypt LOB data using a stream or block cipher with a user supplied key and optional IV (initialization vector).

### Syntax

```
DBMS_CRYPTO.ENCRYPT(
  dst IN OUT NOCOPY BLOB,
  src IN              BLOB,
  typ IN              PLS_INTEGER,
  key IN              RAW,
  iv IN              RAW          DEFAULT NULL);

DBMS_CRYPTO.ENCRYPT(
  dst IN OUT NOCOPY BLOB,
  src IN              CLOB          CHARACTER SET ANY_CS,
  typ IN              PLS_INTEGER,
  key IN              RAW,
  iv IN              RAW          DEFAULT NULL);
```

### Pragmas

```
pragma restrict_references (encrypt, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 43-14 ENCRYPT Procedure Parameters**

| Parameter Name | Description                                                                        |
|----------------|------------------------------------------------------------------------------------|
| dst            | LOB locator of output data. The value in the output LOB <dst> will be overwritten. |
| src            | LOB locator of input data.                                                         |
| typ            | Stream or block cipher type and modifiers to be used.                              |

**Table 43-14 (Cont.) ENCRYPT Procedure Parameters**

| Parameter Name | Description                                                        |
|----------------|--------------------------------------------------------------------|
| key            | Encryption key to be used for encrypting data.                     |
| iv             | Optional initialization vector for block ciphers. Default is NULL. |

**Usage Notes**

See [DBMS\\_DEBUG Operational Notes](#) for more information about the conversion rules for the ENCRYPT procedure.

## 43.9.5 HASH Function

A one-way hash function takes a variable-length input string, the data, and converts it to a fixed-length (generally smaller) output string called a *hash value*. The hash value serves as a unique identifier (like a fingerprint) of the input data. You can use the hash value to verify whether data has been changed or not.

Note that a one-way hash function is a hash function that works in one direction. It is easy to compute a hash value from the input data, but it is hard to generate data that hashes to a particular value. Consequently, one-way hash functions work well to ensure data integrity. Refer to “When to Use Hash or Message Authentication Code (MAC) Functions” in [DBMS\\_CRYPTO Operational Notes](#) for more information about using one-way hash functions.

This function applies to data one of the supported cryptographic hash algorithms listed in [Table 43-3](#).

**Syntax**

```
DBMS_CRYPTO.Hash (  
    src IN RAW,  
    typ IN PLS_INTEGER)  
RETURN RAW;  
  
DBMS_CRYPTO.Hash (  
    src IN BLOB,  
    typ IN PLS_INTEGER)  
RETURN RAW;  
  
DBMS_CRYPTO.Hash (  
    src IN CLOB CHARACTER SET ANY_CS,  
    typ IN PLS_INTEGER)  
RETURN RAW;
```

**Pragmas**

```
pragma restrict_references (hash, WNDS, RNDS, WNPS, RNPS);
```

**Parameters****Table 43-15 HASH Function Parameters**

| Parameter Name | Description                   |
|----------------|-------------------------------|
| src            | The source data to be hashed. |

**Table 43-15 (Cont.) HASH Function Parameters**

| Parameter Name | Description                    |
|----------------|--------------------------------|
| typ            | The hash algorithm to be used. |

**Usage Note**

Oracle recommends that you use the SHA-1 (Secure Hash Algorithm) or SHA-2 because it is more resistant to brute-force attacks than MD4 or MD5. If you must use a Message Digest algorithm, then MD5 provides greater security than MD4.

## 43.9.6 MAC Function

This function applies Message Authentication Code (MAC) algorithms to data to provide keyed message protection.

A MAC is a key-dependent one-way hash function. MACs have the same properties as the one-way hash function described in [HASH Function](#), but they also include a key. Only someone with the identical key can verify the hash. Also refer to “When to Use Hash or Message Authentication Code (MAC) Functions” in [DBMS\\_CRYPTO Operational Notes](#) for more information about using MACs.

See [Table 43-4](#) for a list of MAC algorithms that have been defined for this package.

**Syntax**

```
DBMS_CRYPTO.MAC (  
    src IN RAW,  
    typ IN PLS_INTEGER,  
    key IN RAW)  
RETURN RAW;  
  
DBMS_CRYPTO.MAC (  
    src IN BLOB,  
    typ IN PLS_INTEGER,  
    key IN RAW)  
RETURN RAW;  
  
DBMS_CRYPTO.MAC (  
    src IN CLOB CHARACTER SET ANY_CS,  
    typ IN PLS_INTEGER,  
    key IN RAW)  
RETURN RAW;
```

**Pragmas**

```
pragma restrict_references (mac, WNDS, RNDS, WNPS, RNPS);
```

**Parameters****Table 43-16 MAC Function Parameters**

| Parameter Name | Description                                            |
|----------------|--------------------------------------------------------|
| src            | Source data to which MAC algorithms are to be applied. |
| typ            | MAC algorithm to be used.                              |

**Table 43-16 (Cont.) MAC Function Parameters**

| Parameter Name | Description                       |
|----------------|-----------------------------------|
| key            | Key to be used for MAC algorithm. |

## 43.9.7 PKDECRYPT Function

This function decrypts RAW data using a private key assisted with key algorithm and encryption algorithm and returns decrypted data.

### Syntax

```
DBMS_CRYPTO.PKDECRYPT(  
    src IN RAW,  
    prv_key IN RAW,  
    pubkey_alg IN BINARY_INTEGER,  
    enc_alg IN BINARY_INTEGER)  
RETURN RAW;
```

### Parameters

**Table 43-17 PKDECRYPT Function Parameters**

| Parameter Name | Description                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|
| src            | RAW data to be decrypted.                                                                                    |
| prv_key        | Private key.                                                                                                 |
| pubkey_alg     | Specify the KEY_TYPE_RSA RSA key type.                                                                       |
| enc_alg        | Specify the algorithm PKENCRYPT_RSA_PKCS1_OAEP, for RSA Public Key Cryptosystem with PKCS1 and OAEP padding. |

## 43.9.8 PKENCRYPT Function

This function encrypts RAW data using a public key assisted with key algorithm and encryption algorithm and returns encrypted data.

### Syntax

```
DBMS_CRYPTO.PKENCRYPT(  
    src IN RAW,  
    pub_key IN RAW,  
    pubkey_alg IN BINARY_INTEGER,  
    enc_alg IN BINARY_INTEGER)  
RETURN RAW;
```

### Parameters

**Table 43-18 PKENCRYPT Function Parameters**

| Parameter Name | Description               |
|----------------|---------------------------|
| src            | RAW data to be encrypted. |
| pub_key        | Public key.               |

**Table 43-18 (Cont.) PKENCRYPT Function Parameters**

| Parameter Name | Description                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|
| pubkey_alg     | Specify the KEY_TYPE_RSA RSA key type.                                                                       |
| enc_alg        | Specify the algorithm PKENCRYPT_RSA_PKCS1_OAEP, for RSA Public Key Cryptosystem with PKCS1 and OAEP padding. |

## 43.9.9 RANDOMBYTES Function

This function returns a `RAW` value containing a cryptographically secure pseudo-random sequence of bytes, which can be used to generate random material for encryption keys.

The `RANDOMBYTES` function is based on the RSA X9.31 PRNG (Pseudo-Random Number Generator).

### Syntax

```
DBMS_CRYPTO.RANDOMBYTES (  
    number_bytes IN POSITIVE)  
RETURN RAW;
```

### Pragmas

```
pragma restrict_references (randombytes, WNDS, RNDS, WNPS, RNPS);
```

### Parameters

**Table 43-19 RANDOMBYTES Function Parameter**

| Parameter Name | Description                                        |
|----------------|----------------------------------------------------|
| number_bytes   | The number of pseudo-random bytes to be generated. |

### Usage Note

The `number_bytes` value should not exceed the maximum length of a `RAW` variable.

## 43.9.10 RANDOMINTEGER Function

This function returns an integer in the complete range available for the Oracle `BINARY_INTEGER` datatype.

### Syntax

```
DBMS_CRYPTO.RANDOMINTEGER  
RETURN BINARY_INTEGER;
```

### Pragmas

```
pragma restrict_references (randominteger, WNDS, RNDS, WNPS, RNPS);
```

## 43.9.11 RANDOMNUMBER Function

This function returns an integer in the Oracle `NUMBER` datatype in the range of `[0..2**128-1]`.

### Syntax

```
DBMS_CRYPTO.RANDOMNUMBER  
RETURN NUMBER;
```

### Pragmas

```
pragma restrict_references(randomnumber,WNDS,RNDS,WNPS,RNPS);
```

## 43.9.12 SIGN Function

This function signs `RAW` data using a private key assisted with key algorithm and sign algorithm, and returns a signature.

### Syntax

```
DBMS_CRYPTO.SIGN(  
    src IN RAW,  
    prv_key IN RAW,  
    pubkey_alg IN BINARY_INTEGER,  
    sign_alg IN BINARY_INTEGER)  
RETURN RAW;
```

### Parameters

**Table 43-20 SIGN Function Parameters**

| Parameter Name          | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| <code>src</code>        | RAW data to be signed.                                            |
| <code>prv_key</code>    | Private key.                                                      |
| <code>pubkey_alg</code> | Specify the <code>KEY_TYPE_RSA</code> RSA key type.               |
| <code>sign_alg</code>   | Specify one of the algorithms that are listed in the Usage Notes. |

### Usage Notes

**Table 43-21 SHA Hash Algorithms**

| Hash Algorithm                    | Description                                         |
|-----------------------------------|-----------------------------------------------------|
| <code>SIGN_SHA1_RSA</code>        | SHA1 hash function with RSA                         |
| <code>SIGN_SHA1_RSA_X931</code>   | SHA1 hash function with RSA and X931 padding        |
| <code>SIGN_SHA224_RSA</code>      | SHA 224 bit hash function with RSA                  |
| <code>SIGN_SHA256_RSA</code>      | SHA 256 bit hash function with RSA                  |
| <code>SIGN_SHA256_RSA_X931</code> | SHA 256 bit hash function with RSA and X931 padding |
| <code>SIGN_SHA384_RSA</code>      | SHA 384 bit hash function with RSA                  |
| <code>SIGN_SHA384_RSA_X931</code> | SHA 384 bit hash function with RSA and X931 padding |
| <code>SIGN_SHA512_RSA</code>      | SHA 384 bit hash function with RSA                  |

**Table 43-21 (Cont.) SHA Hash Algorithms**

| Hash Algorithm       | Description                                         |
|----------------------|-----------------------------------------------------|
| SIGN_SHA512_RSA_X931 | SHA 384 bit hash function with RSA and X931 padding |

## 43.9.13 VERIFY Function

This function verifies RAW data using the signature, public key assisted with key algorithm, and sign algorithm. It returns TRUE if the signature was verified.

### Syntax

```
DBMS_CRYPTO.VERIFY(  
    src IN RAW,  
    sign IN RAW,  
    pub_key IN RAW,  
    pubkey_alg IN BINARY_INTEGER,  
    sign_alg IN BINARY_INTEGER)  
RETURN BOOLEAN;
```

### Parameters

**Table 43-22 VERIFY Function Parameters**

| Parameter Name | Description                                                    |
|----------------|----------------------------------------------------------------|
| src            | RAW data to be verified.                                       |
| sign           | Message signature.                                             |
| pub_key        | Public key.                                                    |
| pubkey_alg     | Specify the KEY_TYPE_RSA RSA key type.                         |
| sign_alg       | Specify one of the algorithms that are listed the Usage Notes. |

### Usage Notes

**Table 43-23 SHA Hash Algorithms**

| Hash Algorithm       | Description                                         |
|----------------------|-----------------------------------------------------|
| SIGN_SHA1_RSA        | SHA hash function with RSA                          |
| SIGN_SHA1_RSA_X931   | SHA hash function with RSA and X931 padding         |
| SIGN_SHA224_RSA      | SHA 224 bit hash function with RSA                  |
| SIGN_SHA256_RSA      | SHA 256 bit hash function with RSA                  |
| SIGN_SHA256_RSA_X931 | SHA 256 bit hash function with RSA and X931 padding |
| SIGN_SHA384_RSA      | SHA 384 bit hash function with RSA                  |
| SIGN_SHA384_RSA_X931 | SHA 384 bit hash function with RSA and X931 padding |
| SIGN_SHA512_RSA      | SHA 384 bit hash function with RSA                  |
| SIGN_SHA512_RSA_X931 | SHA 384 bit hash function with RSA and X931 padding |

## DBMS\_CSX\_ADMIN

The `DBMS_CSX_ADMIN` package provides an interface to customize the setup when transporting a tablespace containing binary XML data.

The chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Summary of DBMS\\_CSX\\_ADMIN](#)

### 44.1 DBMS\_CSX\_ADMIN Overview

This package can be used by DBAs to customize the setup when transporting a tablespace containing binary XML data. The use of the package is not required in order for a transportable tablespace job to run.

By default, all binary XML tables will use the default token table set, which will be replicated during transport on the target database. To avoid the cost of transporting a potentially large token table set, the DBA may opt for registering a new set of token tables for a given tablespace. The package provides routines for token table set registration and lookup.

### 44.2 DBMS\_CSX\_ADMIN Security Model

Owned by `XDB`, the `DBMS_CSX_ADMIN` package must be created by `SYS` or `XDB`. The `EXECUTE` privilege is granted to `SYS` or `XDB` or `DBA`. Subprograms in this package are executed using the privileges of the current user.

### 44.3 DBMS\_CSX\_ADMIN Constants

The `DBMS_CSX_ADMIN` package uses several constants.

These are described in the following table.

**Table 44-1 DBMS\_CSX\_ADMIN Constants**

| Name                       | Type                        | Value | Description                                                                |
|----------------------------|-----------------------------|-------|----------------------------------------------------------------------------|
| <code>DEFAULT_LEVEL</code> | <code>BINARY_INTEGER</code> | 0     | Default token table                                                        |
| <code>TAB_LEVEL</code>     | <code>BINARY_INTEGER</code> | 1     | Token table set associated with tables, not tablespaces                    |
| <code>TBS_LEVEL</code>     | <code>BINARY_INTEGER</code> | 2     | Token table set associated with a tablespace                               |
| <code>NO_CREATE</code>     | <code>BINARY_INTEGER</code> | 0     | Token tables already exist, associate them with the given table/tablespace |

**Table 44-1 (Cont.) DBMS\_CSX\_ADMIN Constants**

| Name            | Type           | Value | Description                                                     |
|-----------------|----------------|-------|-----------------------------------------------------------------|
| NO_INDEXES      | BINARY_INTEGER | 1     | Do not create indexes on the new set of token tables            |
| WITH_INDEXES    | BINARY_INTEGER | 2     | Create indexes on the token tables                              |
| DEFAULT_TOKS    | BINARY_INTEGER | 0     | Prepopulate the token tables with default token mappings        |
| NO_DEFAULT_TOKS | BINARY_INTEGER | 1     | Do not prepopulate the token tables with default token mappings |

## 44.4 Summary of DBMS\_CSX\_ADMIN Subprograms

This table lists and describes the DBMS\_CSX\_ADMIN Package subprograms.

**Table 44-2 DBMS\_CSX\_ADMIN Package Subprograms**

| Subprogram                                                 | Description                                                                 |
|------------------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">GETTOKENTABLEINFO Procedure &amp; Function</a> | Returns the GUID of the token table set where token mappings for this table |
| <a href="#">GETTOKENTABLEINFOBYTABLESPACE Procedure</a>    | Returns the GUID and the token table names for this tablespace              |
| <a href="#">NAMESPACEIDTABLE Function</a>                  | Returns default namespace-ID token table                                    |
| <a href="#">PATHIDTABLE Function</a>                       | Returns the default path-ID token table                                     |
| <a href="#">QNAMEIDTABLE Function</a>                      | Returns the default qname-ID token table.                                   |

### 44.4.1 GETTOKENTABLEINFO Procedure & Function

This procedure is overloaded. The specific forms of functionality are described along with the syntax declarations.

Given the table name and the owner, the first overload of the procedure returns the globally unique identifier (GUID) of the token table set where token mappings for this table can be found. The procedure returns also the names of the token tables, and whether the token table set is the default one.

Given the object number of a table, the second overload of the procedure returns the GUID of the token table set used by the table, and whether this is the default token table set.

#### Syntax

```
DBMS_CSX_ADMIN.GETTOKENTABLEINFO (
  ownername      IN   VARCHAR2,
  tablename      IN   VARCHAR2,
  guid           OUT  RAW,
  qnametable     OUT  VARCHAR2,
  nmspctable     OUT  VARCHAR2,
  level          OUT  NUMBER,
  tabno          OUT  NUMBER);
```

```
DBMS_CSX_ADMIN.GETTOKENTABLEINFO (
  tabno          IN   NUMBER,
```

```
    guid          OUT RAW);  
RETURN BOOLEAN;
```

### Parameters

**Table 44-3 GETTOKENTABLEINFO Procedure & Function Parameters**

| Parameter  | Description                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ownername  | Owner of the table                                                                                                                                               |
| tablename  | Name of the table                                                                                                                                                |
| guid       | GUID of the token table set used by the given table                                                                                                              |
| qnametable | Name of the qname-ID table in the new set                                                                                                                        |
| nmspctable | Name of the namespace-ID table in the new set                                                                                                                    |
| level      | DEFAULT_LEVEL if default token table set, TBS_LEVEL if same token table set is used by all tables in the same tablespace as the given table, TAB_LEVEL otherwise |
| tabno      | Table object number                                                                                                                                              |

## 44.4.2 GETTOKENTABLEINFOBYTABLESPACE Procedure

Given a tablespace number, this procedure returns the GUID and the token table names for this tablespace.

### Syntax

```
DBMS_CSX_ADMIN.GETTOKENTABLEINFOBYTABLESPACE (  
    tsname          IN  VARCHAR2,  
    tablespaceno    IN  NUMBER,  
    guid            OUT RAW,  
    qnametable      OUT VARCHAR2,  
    nmspctable      OUT VARCHAR2,  
    isdefault       OUT BOOLEAN,  
    containTokTab   OUT BOOLEAN);
```

### Parameters

**Table 44-4 GETTOKENTABLEINFOBYTABLESPACE Procedure Parameters**

| Parameter     | Description                                                          |
|---------------|----------------------------------------------------------------------|
| tsname        | Tablespace name                                                      |
| tablespaceno  | Tablespace number                                                    |
| guid          | GUID of the token table set associated with this tablespace (if any) |
| qnametable    | Name of the qname-ID table                                           |
| nmspctable    | Name of the namespace-ID table                                       |
| isdefault     | TRUE if the token table is the default one                           |
| containTokTab | TRUE if the tablespace contains its own token table set              |

### 44.4.3 NAMESPACEIDTABLE Function

This procedure returns default namespace-ID token table.

#### Syntax

```
DBMS_CSX_ADMIN.NAMESPACEIDTABLE  
RETURN VARCHAR2;
```

### 44.4.4 PATHIDTABLE Function

This procedure returns the default path-ID token table. This is used for granting permissions on the default path-ID token table for a user before executing `EXPLAIN PLAN` for a query on an XML table with an XML index.

#### Syntax

```
DBMS_CSX_ADMIN.PATHIDTABLE  
RETURN VARCHAR2;
```

### 44.4.5 QNAMEIDTABLE Function

This procedure returns the default qname-ID token table.

#### Syntax

```
DBMS_CSX_ADMIN.QNAMEIDTABLE  
RETURN VARCHAR2;
```

# DBMS\_CUBE

DBMS\_CUBE contains subprograms that create OLAP cubes and dimensions, and that load and process the data for querying.

## See Also:

OLAP Technology in the Oracle Database in *Oracle OLAP User's Guide* regarding use of the OLAP option to support business intelligence and analytical applications.

This chapter contains the following topics:

- [Using DBMS\\_CUBE](#)
- [Using SQL Aggregation Management](#)
- [Upgrading 10g Analytic Workspaces](#)
- [Summary of DBMS\\_CUBE Subprograms](#)

## 45.1 Using DBMS\_CUBE

Cubes and cube dimensions are first class data objects that support multidimensional analytics. They are stored in a container called an analytic workspace. Multidimensional objects and analytics are available with the OLAP option to Oracle Database.

Cubes can be enabled as cube materialized views for automatic refresh of the cubes and dimensions, and for query rewrite. Several DBMS\_CUBE subprograms support the creation and maintenance of cube materialized views as a replacement for relational materialized views. These subprograms are discussed in "[Using SQL Aggregation Management](#)".

The metadata for cubes and dimensions is defined in XML documents, called *templates*, which you can derive from relational materialized views using the CREATE\_CUBE or DERIVE\_FROM\_MVIEW functions. Using a graphical tool named Analytic Workspace Manager, you can enhance the cube with analytic content or create the metadata for new cubes and cube dimensions from scratch.

Several other DBMS\_CUBE subprograms provide a SQL alternative to Analytic Workspace Manager for creating an analytic workspace from an XML template and for refreshing the data stored in cubes and dimensions. The IMPORT\_XML procedure creates an analytic workspace with its cubes and cube dimensions from an XML template. The BUILD procedure loads data into the cubes and dimensions from their data sources and performs whatever processing steps are needed to prepare the data for querying.

## 45.1.1 DBMS\_CUBE Security Model

Certain roles and system privileges are required to use the DBMS\_CUBE package.

**To create dimensional objects in the user's own schema:**

- OLAP\_USER role
- CREATE SESSION privilege

**To create dimensional objects in different schemas:**

- OLAP\_DBA role
- CREATE SESSION privilege

**To create cube materialized views in the user's own schema:**

- CREATE MATERIALIZED VIEW privilege
- CREATE DIMENSION privilege
- ADVISOR privilege

**To create cube materialized views in different schemas:**

- CREATE ANY MATERIALIZED VIEW privilege
- CREATE ANY DIMENSION privilege
- ADVISOR privilege

If the source tables are in a different schema, then the owner of the dimensional objects needs SELECT object privileges on those tables.

## 45.2 Using SQL Aggregation Management

SQL Aggregation Management is a group of PL/SQL subprograms in DBMS\_CUBE that supports the rapid deployment of cube materialized views from existing relational materialized views.

Cube materialized views are cubes that have been enhanced to use the automatic refresh and query rewrite features of Oracle Database. A single cube materialized view can replace many of the relational materialized views of summaries on a fact table, providing uniform response time to all summary data.

Cube materialized views bring the fast update and fast query capabilities of the OLAP option to applications that query summaries of detail relational tables. The summary data is generated and stored in a cube, and query rewrite automatically redirects queries to the cube materialized views. Applications experience excellent querying performance.

In the process of creating the cube materialized views, DBMS\_CUBE also creates a fully functional analytic workspace including a cube and the cube dimensions. The cube stores the data for a cube materialized view instead of the table that stores the data for a relational materialized view. A cube can also support a wide range of analytic functions that enhance the database with information-rich content.

Cube materialized views are registered in the data dictionary along with all other materialized views. A CB\$ prefix identifies a cube materialized view.

The DBMS\_CUBE subprograms also support life-cycle management of cube materialized views.

**See Also:**

Adding Materialized View Capability to a Cube in *Oracle OLAP User's Guide* for more information about cube materialized views and enhanced OLAP analytics.

## 45.2.1 Subprograms in SQL Aggregation Management

SQL Aggregation Management includes four subprograms.

- [CREATE\\_MVIEW Function](#)
- [DERIVE\\_FROM\\_MVIEW Function](#)
- [DROP\\_MVIEW Procedure](#)
- [REFRESH\\_MVIEW Procedure](#)

## 45.2.2 Requirements for the Relational Materialized View

SQL Aggregation Management uses an existing relational materialized view to derive all the information needed to generate a cube materialized view. The relational materialized view determines the detail level of data that is stored in the cube materialized view. The related relational dimension objects determine the scope of the aggregates, from the lowest level specified in the `GROUP BY` clause of the materialized view subquery, to the highest level of the dimension hierarchy.

The relational materialized view must conform to these requirements:

- Explicit `GROUP BY` clause for one or more columns.
  - No expressions in the select list or `GROUP BY` clause.
  - At least one of these numeric aggregation methods: `SUM`, `MIN`, `MAX`, or `AVG`.
  - No outer joins.
  - Summary keys with at least one simple column associated with a relational dimension.
- or**
- Summary keys with at least one simple column and no hierarchies or levels.
- Numeric datatype of any type for the fact columns. All facts are converted to `NUMBER`.
  - Eligible for rewrite. `REWRITE_CAPABILITY` should be `GENERAL`; it cannot be `NONE`. Refer to the `ALL_MVIEWS` entry in the *Oracle Database Reference*.
  - Cannot use the `DISTINCT` or `UNIQUE` keywords with an aggregate function in the defining query. For example, `AVG(DISTINCT units)` causes an error in `STRICT` mode and is ignored in `LOOSE` mode.

You can choose between two modes when rendering the cube materialized view, `LOOSE` and `STRICT`. In `STRICT` mode, any deviation from the requirements raises an exception and prevents the materialized view from being created. In `LOOSE` mode (the default), some deviations are allowed, but they affect the content of the materialized view. These elements in the relational materialized view generate warning messages:

- Complex expressions in the defining query are ignored and do not appear in the cube materialized view.

- The `AVG` function is changed to `SUM` and `COUNT`.
- The `COUNT` function without a `SUM`, `MIN`, `MAX`, or `AVG` function is ignored.
- The `STDDEV` and `VARIANCE` functions are ignored.

You can also choose how conditions in the `WHERE` clause are filtered. When filtering is turned off, the conditions are ignored. When turned on, valid conditions are rendered in the cube materialized view, but asymmetric conditions among dimension levels raise an exception.

## 45.2.3 Permissions for Managing and Querying Cube Materialized Views

Certain permissions are required to manage and query cube materialized views.

To create cube materialized views, you must have these privileges:

- `CREATE [ANY] MATERIALIZED VIEW` privilege
- `CREATE [ANY] DIMENSION` privilege
- `ADVISOR` privilege

To access cube materialized views from another schema using query rewrite, you must have these privileges:

- `GLOBAL QUERY REWRITE` privilege
- `SELECT` or `READ` privilege on the relational source tables
- `SELECT` or `READ` privilege on the analytic workspace (`AW$name`) that supports the cube materialized view
- `SELECT` or `READ` privilege on the cube
- `SELECT` or `READ` privilege on the dimensions of the cube

Note that you need `SELECT` or `READ` privileges on the database objects that *support* the cube materialized views, but not on the cube materialized views.

## 45.2.4 Example of SQL Aggregation Management

Six examples of SQL Aggregate Management are given. All these examples use the sample Sales History schema, which is installed in Oracle Database with two relational materialized views: `CAL_MONTH_SALES_MV` and `FWEEK_PSCAT_SALES_MV`.

- About Relational Materialized View `CAL_MONTH_SALES_MV`
- Creating the Cube Materialized View
- Disabling the Relational Materialized Views
- Creating Execution Plans for Cube Materialized Views
- Maintaining Cube Materialized Views
- New Database Objects

### About Relational Materialized View `CAL_MONTH_SALES_MV`

This example uses `CAL_MONTH_SALES_MV` as the basis for creating a cube materialized view. The following query was used to create `CAL_MONTH_SALES_MV`. `CAL_MONTH_SALES_MV` summarizes the daily sales data stored in the `SALES` table by month.

```
SELECT query FROM user_mviews
      WHERE mview_name='CAL_MONTH_SALES_MV';
```

```
QUERY
```

```
-----
SELECT   t.calendar_month_desc
      ,   sum(s.amount_sold) AS dollars
FROM     sales s
      ,   times t
WHERE    s.time_id = t.time_id
GROUP BY t.calendar_month_desc
```

DBMS\_CUBE uses relational dimensions to derive levels and hierarchies for the cube materialized view. The SH schema has relational dimensions for most dimension tables in the schema, as shown by the following query.

```
SELECT dimension_name FROM user_dimensions;
```

```
DIMENSION_NAME
```

```
-----
CUSTOMERS_DIM
PRODUCTS_DIM
TIMES_DIM
CHANNELS_DIM
PROMOTIONS_DIM
```

### Creating the Cube Materialized View

This PL/SQL script uses the CREATE\_MVIEW function to create a cube materialized view from CAL\_MONTH\_SALES\_MV. CREATE\_MVIEW sets the optional BUILD parameter to refresh the cube materialized view immediately.

```
SET serverout ON format wrapped
```

```
DECLARE
    salesaw varchar2(30);

BEGIN
    salesaw := dbms_cube.create_mview('SH', 'CAL_MONTH_SALES_MV',
                                     'build=immediate');

END;
/
```

These messages confirm that the script created and refreshed CB\$CAL\_MONTH\_SALES successfully:

```
Completed refresh of cube mview "SH"."CB$CAL_MONTH_SALES" at 20130212 08:42:58.0
03.
Created cube organized materialized view "CB$CAL_MONTH_SALES" for rewrite at 200
130212 08:42:58.004.
```

The following query lists the materialized views in the SH schema:

```
SELECT mview_name FROM user_mviews;
```

```
MVIEW_NAME
```

```
-----
CB$CAL_MONTH_SALES
CB$TIMES_DIM_D1_CAL_ROLLUP
CAL_MONTH_SALES_MV
FWEEK_PSCAT_SALES_MV
```

Two new materialized views are registered in the data dictionary:

- CB\$CAL\_MONTH\_SALES: Cube materialized view
- CB\$TIMES\_DIM\_D1\_CAL\_ROLLUP: Cube dimension materialized view for the TIME\_DIM Calendar Rollup hierarchy

Cube dimension materialized views support refresh of the cube materialized view. You do not directly administer dimension materialized views.

### Disabling the Relational Materialized Views

After creating a cube materialized view, disable query rewrite on all relational materialized views for the facts now supported by the cube materialized view. You can drop them when you are sure that you created the cube materialized view with the optimal parameters.

```
ALTER MATERIALIZED VIEW cal_month_sales_mv DISABLE QUERY REWRITE;
```

Materialized view altered.

You can also use the `DISABLEQRW` parameter in the `CREATE_MVIEW` function, which disables query rewrite on the source materialized view as described in [Table 45-7](#).

### Creating Execution Plans for Cube Materialized Views

You can create execution plans for cube materialized views the same as for relational materialized views. The following command generates an execution plan for a query against the `SALES` table, which contains data at the day level. The answer set requires data summarized by quarter. Query rewrite would not use the original relational materialized view for this query, because its data is summarized by month. However, query rewrite can use the new cube materialized view for summary data for months, quarters, years, and all years.

```
EXPLAIN PLAN FOR SELECT
    t.calendar_quarter_desc,
    sum(s.amount_sold) AS dollars
FROM    sales s,
        times t
WHERE   s.time_id = t.time_id
AND     t.calendar_quarter_desc LIKE '2001%'
GROUP BY t.calendar_quarter_desc
ORDER BY t.calendar_quarter_desc;
```

The query returns these results:

| CALENDAR_QUARTER_DESC | DOLLARS    |
|-----------------------|------------|
| 2001-01               | 6547097.44 |
| 2001-02               | 6922468.39 |
| 2001-03               | 7195998.63 |
| 2001-04               | 7470897.52 |

The execution plan shows that query rewrite returned the summary data from the cube materialized view, `CB$CAL_MONTH_SALES`, instead of recalculating it from the `SALES` table.

```
SELECT plan_table_output FROM TABLE(dbms_xplan.display());
```

```
PLAN_TABLE_OUTPUT
```

```
Plan hash value: 2999729407
```

| Id | Operation | Name | Rows | Bytes | Cost (%CPU) | Time |
|----|-----------|------|------|-------|-------------|------|
|----|-----------|------|------|-------|-------------|------|

|   |   |  |                              |  |                     |  |   |  |    |  |   |      |  |          |  |
|---|---|--|------------------------------|--|---------------------|--|---|--|----|--|---|------|--|----------|--|
|   | 0 |  | SELECT STATEMENT             |  |                     |  | 1 |  | 30 |  | 3 | (34) |  | 00:00:01 |  |
|   | 1 |  | SORT GROUP BY                |  |                     |  | 1 |  | 30 |  | 3 | (34) |  | 00:00:01 |  |
| * | 2 |  | MAT_VIEW REWRITE CUBE ACCESS |  | CB\$CAL_MONTH_SALES |  | 1 |  | 30 |  | 2 | (0)  |  | 00:00:01 |  |

Predicate Information (identified by operation id):

```

2 - filter("CB$CAL_MONTH_SALES"."D1_CALENDAR_QUARTER_DESC" LIKE '2001%' AND
          "CB$CAL_MONTH_SALES"."SYS_GID"=63)

```

15 rows selected.

## Maintaining Cube Materialized Views

You can create a cube materialized view that refreshes automatically. However, you can force a refresh at any time using the [REFRESH\\_MVIEW Procedure](#):

```

BEGIN
    dbms_cube.refresh_mview('SH', 'CB$CAL_MONTH_SALES');
END;
/

```

Completed refresh of cube mview "SH"."CB\$CAL\_MONTH\_SALES" at 20130212 14:30:59.534.

If you want to drop a cube materialized view, use the [DROP\\_MVIEW Procedure](#) so that all supporting database objects (analytic workspace, cube, cube dimensions, and so forth) are also dropped:

```

BEGIN
    dbms_cube.drop_mview('SH', 'CB$CAL_MONTH_SALES');
END;
/

```

Dropped cube organized materialized view "SH"."CAL\_MONTH\_SALES" including container analytic workspace "SH"."CAL\_MONTH\_SALES\_AW" at 20130212 13:38:47.878.

## New Database Objects

The `CREATE_MVIEW` function creates several first class database objects in addition to the cube materialized views. You can explore these objects through the data dictionary by querying views such as `ALL_CUBES` and `ALL_CUBE_DIMENSIONS`.

This example created the following supporting objects:

- Analytic workspace `CAL_MONTH_SALES_AW` (`AW$CAL_MONTH_SALES_AW` table)
- Cube `CAL_MONTH_SALES`
- Cube dimension `TIMES_DIM_D1`
- Dimension hierarchy `CAL_ROLLUP`
- Dimension levels `ALL_TIMES_DIM`, `YEAR`, `QUARTER`, and `MONTH`
- Numerous attributes for levels in the `CAL_ROLLUP` hierarchy

## 45.3 Upgrading 10g Analytic Workspaces

You can upgrade an OLAP 10g analytic workspace to OLAP 12c by saving the OLAP 10g objects as an XML template and importing the XML into a different schema. The original analytic workspace remains accessible and unchanged by the upgrade process.

Oracle OLAP metadata is the same in OLAP 11g and OLAP 12c so you do not need to upgrade an OLAP 11g analytic workspace to OLAP 12c. This topic describes upgrading an Oracle OLAP 10g analytic workspace to OLAP 12c.

 **Tip:**

Oracle recommends using Analytic Workspace Manager for performing upgrades. See Upgrading Metadata From Oracle OLAP 10g in *Oracle OLAP User's Guide*.

These subprograms in `DBMS_CUBE` support the upgrade process:

- [CREATE\\_EXPORT\\_OPTIONS Procedure](#)
- [CREATE\\_IMPORT\\_OPTIONS Procedure](#)
- [EXPORT\\_XML Procedure](#)
- [EXPORT\\_XML\\_TO\\_FILE Procedure](#)
- [IMPORT\\_XML Procedure](#)
- [INITIALIZE\\_CUBE\\_UPGRADE Procedure](#)
- [UPGRADE\\_AW Procedure](#)

**Prerequisites:**

- The OLAP 10g analytic workspace can use OLAP standard form metadata.
- Customizations to the OLAP 10g analytic workspace may not be exported to the XML template. You must re-create them in OLAP 12c.
- The original relational source data must be available to load into the new analytic workspace. If the data is in a different schema or the table names are different, then you must remap the dimensional objects to the new relational sources after the upgrade.
- You can create the OLAP 12c analytic workspace in the same schema as the OLAP 10g analytic workspace. However, if you prefer to create it in a different schema, then create a new user with the following privileges:
  - `SELECT` or `READ` privileges on the OLAP 10g analytic workspace (`GRANT SELECT ON schema.AW$analytic_workspace`).
  - `SELECT` or `READ` privileges on all database tables and views that contain the source data for the OLAP 10g analytic workspace.
  - Appropriate privileges for an OLAP administrator.
  - Same default tablespace as the Oracle 10g user.

See the *Oracle OLAP User's Guide*.

## Correcting Naming Conflicts

The namespaces are different in OLAP 10g than those in OLAP 12c. For a successful upgrade, you must identify any 10g object names that are used multiple times under the 12c naming rules and provide unique names for them.

The following namespaces control the uniqueness of OLAP object names in Oracle 12c:

- **Schema:** The names of cubes, dimensions, and measure folders must be unique within a schema. They cannot conflict with the names of tables, views, indexes, relational dimensions, or any other first class objects. However, these OLAP 12c object names do not need to be distinct from 10g object names, because they are in different namespaces.
- **Cube:** The names of measures must be unique within a cube.
- **Dimension:** The names of hierarchies, levels, and attributes must be unique within a dimension. For example, a dimension cannot have a hierarchy named Customers and a level named Customers.

You can use an initialization table and a rename table to rename objects in the upgraded 12c analytic workspace.

### Initialization Table

The `INITIALIZE_CUBE_UPGRADE` procedure identifies ambiguous names under the OLAP 12c naming rules. For example, a 10g dimension might have a hierarchy and a level with the same name. Because hierarchies and levels are in the same 12c namespace, the name is not unique in 12c; to a 12c client, the hierarchy and the level cannot be differentiated by name.

`INITIALIZE_CUBE_UPGRADE` creates and populates a table named `CUBE_UPGRADE_INFO` with unique names for these levels, hierarchies, and attributes. By using the unique names provided in the table, a 12c client can browse the OLAP 12c metadata. You cannot attach an OLAP 12c client to the analytic workspace or perform an upgrade without a `CUBE_UPGRADE_INFO` table, if the 10g metadata contains ambiguous names.

You can edit `CUBE_UPGRADE_INFO` to change the default unique names to names of your choosing. You can also add rows to change the names of any other objects. When using an 12c client, you see the new object names. When using an 10g client, you see the original names. However, the `INITIALIZE_CUBE_UPGRADE` procedure overwrites this table, so you may prefer to enter customizations in a rename table.

During an upgrade from OLAP 10g, the unique object names in `CUBE_UPGRADE_INFO` are used as the names of 12c objects in the new analytic workspace. However, `INITIALIZE_CUBE_UPGRADE` does not automatically provide unique names for cubes, dimensions, and measure folders. To complete an upgrade, you must assure that these objects have unique names within the 12c namespace. You can provide these objects with new names in the `CUBE_UPGRADE_INFO` table or in a rename table.

OLAP 12c clients automatically use `CUBE_UPGRADE_INFO` when it exists in the same schema as the OLAP 10g analytic workspace.

#### See Also:

["INITIALIZE\\_CUBE\\_UPGRADE Procedure"](#)

## Rename Table

You can create a rename table that contains new object names for an OLAP 12c analytic workspace. You can then use the rename table in the `CREATE_IMPORT_OPTIONS` and `UPGRADE_AW` procedures.

When upgrading within the same schema, you must provide a unique name for the 12c analytic workspace. The `UPGRADE_AW` procedure provides a parameter for this purpose; otherwise, you must provide the new name in the rename table. The duplication of cube names does not create ambiguity because the 12c cubes are created in a different namespace than the 10g cubes.

The names provided in a rename table are used only during an upgrade and overwrite any names entered in the `CUBE_UPGRADE_INFO` table.

### To create a rename table:

1. Open SQL\*Plus or another SQL client, and connect to Oracle Database as the owner of the 10g analytic workspace.
2. Issue a command like the following:

```
CREATE TABLE table_name (  
    source_id    VARCHAR2(300),  
    new_name     VARCHAR2(30),  
    object_type  VARCHAR2(30));
```

3. Populate the rename table with the appropriate values, as follows.

`table_name` is the name of the rename table.

`source_id` is the identifier for an object described in the XML document supplied to `IMPORT_XML`. The identifier must have this format:

`schema_name.object_name[.subobject_name]`

`new_name` is the object name given during the import to the object specified by `source_id`.

`object_type` is the object type as described in the XML, such as `StandardDimension` or `DerivedMeasure`.

For example, these SQL statements populate the table with new names for the analytic workspace, a cube, and four dimensions:

```
INSERT INTO my_object_map VALUES('GLOBAL_AW.GLOBAL10.AW', 'GLOBAL12', 'AW');  
INSERT INTO my_object_map VALUES('GLOBAL_AW.UNITS_CUBE', 'UNIT_SALES_CUBE', 'Cube');  
INSERT INTO my_object_map VALUES('GLOBAL_AW.CUSTOMER', 'CUSTOMERS', 'StandardDimension');  
INSERT INTO my_object_map VALUES('GLOBAL_AW.CHANNEL', 'CHANNELS', 'StandardDimension');  
INSERT INTO my_object_map VALUES('GLOBAL_AW.PRODUCT', 'PRODUCTS', 'StandardDimension');  
INSERT INTO my_object_map VALUES('GLOBAL_AW.TIME', 'TIME_PERIODS', 'TimeDimension');
```

### See Also:

["CREATE\\_IMPORT\\_OPTIONS Procedure"](#)

## Simple Upgrade

A simple upgrade creates an OLAP 12c analytic workspace from an OLAP 10g analytic workspace.

**To perform a simple upgrade of an Oracle OLAP 10g analytic workspace:**

1. Open SQL\*Plus or a similar SQL command-line interface and connect to Oracle Database 12c as the schema owner for the OLAP 12c analytic workspace.
2. To rename any objects in the 12c analytic workspace, create a rename table as described in the Rename Table section. (Optional)
3. Perform the upgrade, as described in "[UPGRADE\\_AW Procedure](#)".
4. Use the `DBMS_CUBE.BUILD` procedure to load data into the cube.

### Example 45-1 Performing a Simple Upgrade to the GLOBAL Analytic Workspace

This example creates an OLAP 12c analytic workspace named `GLOBAL12` from an OLAP 10g analytic workspace named `GLOBAL10`. `GLOBAL10` contains no naming conflicts between cubes, dimensions, measure folders, or tables in the schema, so a rename table is not needed in this example.

```
BEGIN

-- Upgrade the analytic workspace
dbms_cube.upgrade_aw(sourceaw => 'GLOBAL10', destaw => 'GLOBAL12');

-- Load and aggregate the data
dbms_cube.build(script => 'UNITS_CUBE, PRICE_AND_COST_CUBE');

END;
/
```

## Custom Upgrade

A custom upgrade enables you to set the export and import options.

**To perform a custom upgrade of an Oracle OLAP 10g analytic workspace:**

1. Open SQL\*Plus or a similar SQL command-line interface and connect to Oracle Database 12c as the schema owner of the OLAP 12c analytic workspace.
2. Generate an initialization table, as described in the Initialization Table section. Review the new, default object names and modify them as desired.
3. Create a rename table, as described in the Rename Table section. If you are upgrading in the same schema, you must use a rename table to provide a unique name for the 12c analytic workspace. Otherwise, a rename table is needed only if names are duplicated among the cubes, dimensions, and measure folders of the analytic workspace, or between those names and the existing cubes, dimensions, measure folders, or tables of the destination schema.
4. Create a SQL script that does the following:
  - a. Create an XML document for the export options, as described in "[CREATE\\_EXPORT\\_OPTIONS Procedure](#)". The `SUPPRESS_NAMESPACE` option must be set to `TRUE` for the upgrade to occur.
  - b. Create an XML document for the import options, as described in "[CREATE\\_IMPORT\\_OPTIONS Procedure](#)".

- c. Create an XML template in OLAP 12c format, as described in "[EXPORT\\_XML Procedure](#)".
  - d. Create an OLAP 12c analytic workspace from the XML template, as described in "[IMPORT\\_XML Procedure](#)".
5. Load and aggregate the data in the new analytic workspace, as described in "[BUILD Procedure](#)".

#### Example 45-2 Performing a Custom Upgrade to the GLOBAL Analytic Workspace

This example upgrades the GLOBAL10 analytic workspace from OLAP 10g metadata to OLAP 12c metadata in the GLOBAL\_AW schema.

The rename table provides the new name of the analytic workspace. These commands define the rename table.

```
CREATE TABLE my_object_map(
    source_id   VARCHAR2(300),
    new_name    VARCHAR2(30),
    object_type VARCHAR2(30));

INSERT INTO my_object_map VALUES('GLOBAL_AW.GLOBAL10.AW', 'GLOBAL12', 'AW');
COMMIT;
```

Following is the script for performing the upgrade.

```
set serverout on

DECLARE
    importClob    clob;
    exportClob    clob;
    exportOptClob clob;
    importOptClob clob;

BEGIN
    -- Create table of reconciled names
    dbms_cube.initialize_cube_upgrade;

    -- Create a CLOB containing the export options
    dbms_lob.createtemporary(exportOptClob, TRUE);
    dbms_cube.create_export_options(out_options_xml=>exportOptClob,
    suppress_namespace=>TRUE, preserve_table_owners=>TRUE);

    -- Create a CLOB containing the import options
    dbms_lob.createtemporary(importOptClob, TRUE);
    dbms_cube.create_import_options(out_options_xml=>importOptClob, rename_table =>
'MY_OBJECT_MAP');

    -- Create CLOBs for the metadata
    dbms_lob.createtemporary(importClob, TRUE);
    dbms_lob.createtemporary(exportClob, TRUE);

    -- Export metadata from a 10g analytic workspace to a CLOB
    dbms_cube.export_xml(object_ids=>'GLOBAL_AW', options_xml=>exportOptClob,
out_xml=>exportClob);

    -- Import metadata from the CLOB
    dbms_cube.import_xml(in_xml => exportClob, options_xml=>importOptClob,
out_xml=>importClob);

    -- Load and aggregate the data
```

```

dbms_cube.build('UNITS_CUBE, PRICE_AND_COST_CUBE');

END;
/

```

## 45.4 Summary of DBMS\_CUBE Subprograms

This table lists and describes the DBMS\_CUBE procedure subprograms.

**Table 45-1 DBMS\_CUBE Subprograms**

| Subprogram                                        | Description                                                                                                 |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">BUILD Procedure</a>                   | Loads data into one or more cubes and dimensions, and prepares the data for querying.                       |
| <a href="#">CREATE_EXPORT_OPTIONS Procedure</a>   | Creates an input XML document of processing options for the EXPORT_XML procedure.                           |
| <a href="#">CREATE_IMPORT_OPTIONS Procedure</a>   | Creates an input XML document of processing options for the IMPORT_XML procedure.                           |
| <a href="#">CREATE_MVIEW Function</a>             | Creates a cube materialized view from the definition of a relational materialized view.                     |
| <a href="#">DERIVE_FROM_MVIEW Function</a>        | Creates an XML template for a cube materialized view from the definition of a relational materialized view. |
| <a href="#">DROP_MVIEW Procedure</a>              | Drops a cube materialized view.                                                                             |
| <a href="#">EXPORT_XML Procedure</a>              | Exports the XML of an analytic workspace to a CLOB.                                                         |
| <a href="#">EXPORT_XML_TO_FILE Procedure</a>      | Exports the XML of an analytic workspace to a file.                                                         |
| <a href="#">IMPORT_XML Procedure</a>              | Creates, modifies, or drops an analytic workspace by using an XML template                                  |
| <a href="#">INITIALIZE_CUBE_UPGRADE Procedure</a> | Processes Oracle OLAP 10g objects with naming conflicts to enable Oracle 12c clients to access them.        |
| <a href="#">REFRESH_MVIEW Procedure</a>           | Refreshes a cube materialized view.                                                                         |
| <a href="#">UPGRADE_AW Procedure</a>              | Upgrades an analytic workspace from Oracle OLAP 10g to 12c.                                                 |
| <a href="#">VALIDATE_XML Procedure</a>            | Checks the XML to assure that it is valid, without committing the results to the database.                  |

### 45.4.1 BUILD Procedure

This procedure loads data into one or more cubes and dimensions, and generates aggregate values in the cubes. The results are automatically committed to the database.

#### Syntax

```

DBMS_CUBE.BUILD (
    script                IN  VARCHAR2,
    method                IN  VARCHAR2          DEFAULT NULL,
    refresh_after_errors IN  BOOLEAN            DEFAULT FALSE,
    parallelism           IN  BINARY_INTEGER    DEFAULT 0,
    atomic_refresh        IN  BOOLEAN            DEFAULT FALSE,
    automatic_order       IN  BOOLEAN            DEFAULT TRUE,
    add_dimensions        IN  BOOLEAN            DEFAULT TRUE,
    scheduler_job         IN  VARCHAR2          DEFAULT NULL,
    master_build_id       IN  BINARY_INTEGER    DEFAULT 0,

```

```
nested          IN  BOOLEAN          DEFAULT FALSE);
job_class       IN  VARCHAR2         DEFAULT 'DEFAULT_JOB_CLASS'
```

## Parameters

**Table 45-2 BUILD Procedure Parameters**

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| script               | A list of cubes and dimensions and their build options (see " <a href="#">SCRIPT Parameter</a> ").                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| method               | <p>A full or a fast (partial) refresh. In a fast refresh, only changed rows are inserted in the cube and the affected areas of the cube are re-aggregated.</p> <p>You can specify a method for each cube and dimension in sequential order, or a single method to apply to all cubes and dimensions. If you list more objects than methods, then the last method applies to the additional objects.</p> <ul style="list-style-type: none"> <li>• C: Complete refresh clears all dimension values before loading. (Default)</li> <li>• F: Fast refresh of a cube materialized view, which performs an incremental refresh and re-aggregation of only changed rows in the source table.</li> <li>• ?: Fast refresh if possible, and otherwise a complete refresh.</li> <li>• P: Recomputes rows in a cube materialized view that are affected by changed partitions in the detail tables.</li> <li>• S: Fast solve of a compressed cube. A fast solve reloads all the detail data and re-aggregates only the changed values.</li> </ul> <p>See the "<a href="#">Usage Notes</a>" for additional details.</p> <p>Methods do not apply to dimensions.</p> |
| refresh_after_errors | <p>TRUE to roll back just the cube or dimension with errors, and then continue building the other objects.</p> <p>FALSE to roll back all objects in the build.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| parallelism          | Number of parallel processes to allocate to this job (see Usage Notes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| atomic_refresh       | <p>TRUE prevents users from accessing intermediate results during a build. It freezes the current state of an analytic workspace at the beginning of the build to provide current sessions with consistent data. This option thaws the analytic workspace at the end of the build to give new sessions access to the refreshed data. If an error occurs during the build, then all objects are rolled back to the frozen state.</p> <p>FALSE enables users to access intermediate results during an build.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| automatic_order      | <p>TRUE enables optimization of the build order. Dimensions are loaded before cubes.</p> <p>FALSE builds objects in the order you list them in the script.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| add_dimensions       | <p>TRUE automatically includes all the dimensions of the cubes in the build, whether or not you list them in the script. If a cube materialized view with a particular dimension is fresh, then that dimension is not reloaded. You can list a cube once in the script.</p> <p>FALSE includes only dimensions specifically listed in the script.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| scheduler_job        | Any text identifier for the job, which will appear in the log table. The string does not need to be unique.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| master_build_id      | A unique name for the build.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 45-2 (Cont.) BUILD Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nested    | TRUE performs nested refresh operations for the specified set of cube materialized views. Nested refresh operations refresh all the depending materialized views and the specified set of materialized views based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables.<br>All objects must reside in a single analytic workspace. |
| job_class | The class this job is associated with.                                                                                                                                                                                                                                                                                                                                                                  |

**SCRIPT Parameter**

The **SCRIPT** parameter identifies the objects to include in the build, and specifies the type of processing to perform on each one. The parameter has this syntax:

```
[VALIDATE | NO COMMIT] objects [ USING ( commands ) ][,...]
```

*Where:*

**VALIDATE** checks all steps of the build and sends the planned steps to **CUBE\_BUILD\_LOG** without executing the steps. You can view all generated SQL in the **OUTPUT** column of the log table.

**NO COMMIT** builds the objects in the current attach mode (or Read Only when the analytic workspace is not attached) but does not commit the changes. This option supports what-if analysis, since it enables you to change data values temporarily. See "[SCRIPT Parameter: USING Clause: SET command](#)".

**objects** is the qualified name of one or more cubes or dimensions, separated by commas, in the form *[aw\_name.]object*, such as **UNITS\_CUBE** or **GLOBAL.UNITS\_CUBE**.

**SCRIPT Parameter: USING Clause**

The **USING** clause specifies the processing options. It consists of one or more commands separated by commas.

**Note:**

A cube with a rewrite materialized view cannot have a **USING** clause, except for the **ANALYZE** command. It uses the default build options.

The **commands** can be any of the following.

- **AGGREGATE USING [MEASURE]**  
Generates aggregate values using the syntax described in "[SCRIPT Parameter: USING Clause: AGGREGATE command](#)".
- **ANALYZE**  
Runs **DBMS\_AW\_STATS.ANALYZE**, which generates and stores optimizer statistics for cubes and dimensions.
- **CLEAR [VALUES | LEAVES | AGGREGATES] [SERIAL | PARALLEL]**

Prepares the cube for a data refresh. It can also be used on dimensions, but `CLEAR` removes all dimension keys, and thus deletes all data values for cubes that use the dimension.

These optional arguments control the refresh method. If you omit the argument, then the behavior of `CLEAR` depends on the refresh method. The 'C' (complete) refresh method runs `CLEAR VALUES`, and all other refresh methods run `CLEAR LEAVES`.

- `VALUES`: Clears all data in the cube. All facts must be reloaded and all aggregates must be recomputed. This option supports the `COMPLETE` refresh method. (Default for the `C` and `F` methods)
- `LEAVES`: Clears the detail data and retains the aggregates. All facts must be reloaded, and the aggregates for any new or changed facts must be computed. This option supports the `FAST` refresh method. (Default for the `?` method)
- `AGGREGATES`: Retains the detail data and clears the aggregates. All aggregates must be recomputed.

These optional arguments control the load method, and can be combined with any of the refresh options:

- `PARALLEL`: Each partition is cleared separately. (Default)
- `SERIAL`: All partitions are cleared together.

If you omit the `CLEAR` command, `DBMS_CUBE` loads new and updated facts, but does not delete any old detail data. This is equivalent to a `LOAD NO SYNC` for dimensions.

- `COMPILE [SORT | NO SORT | SORT ONLY]`

Creates the supporting structures for the dimension. (Dimensions only)

These options control the use of a sort order attribute:

- `SORT`: The user-defined sort order attribute populates the sort column in the embedded-total (ET) view. (Default)
- `NO SORT`: Any sort order attribute is ignored. This option is for very large dimensions where sorting could consume too many resources.
- `SORT ONLY`: The compile step only runs the sort.

- `EXECUTE PLSQL string`

Executes a PL/SQL command or script in the database.

- `EXECUTE OLAP DML string [PARALLEL | SERIAL]`

Executes an OLAP DML command or program in the analytic workspace. The options control execution of the command or program:

- `PARALLEL`: Execute the command or program once for each partition. This option can be used to provide a performance boost to complex DML operations, such as forecasts and models.
- `SERIAL`: Execute the command or program once for the entire cube. (Default)

- `[INSERT | MERGE] INTO [ALL HIERARCHIES | HIERARCHIES (dimension.hierarchy)] VALUES (dim_key, parent, level_name)`

Adds a dimension member to one or more hierarchies. `INSERT` throws an error if the member already exists, while `MERGE` does not. See ["Dimension Maintenance Example"](#).

*dimension.hierarchy*: The name of a hierarchy the new member belongs to. Enclose each part of the name in double quotes, for example, "PRODUCT"."PRIMARY".

*dim\_key*: The DIM\_KEY value of the dimension member.

*parent*: The parent of the dimension key.

*level\_name*: The level of the dimension key.

- UPDATE [ALL HIERARCHIES | HIERARCHIES (*dimension.hierarchy*)] SET PARENT = *parent*, LEVEL=*level\_name* WHERE MEMBER = *dim\_key*

Alters the level or parent of an existing dimension member. See INSERT for a description of the options. Also see "[Dimension Maintenance Example](#)".

- DELETE FROM DIMENSION WHERE MEMBER=*dim\_key*

Deletes a dimension member. See "[Dimension Maintenance Example](#)".

*dim\_key*: The DIM\_KEY value of the dimension member to be deleted.

- SET *dimension.attribute*[*qdr*] = CAST('attribute\_value' AS VARCHAR2))

Sets the value of an attribute for a dimension member. See "[Dimension Maintenance Example](#)".

*dimension.attribute*: The name of the attribute. Enclose each part of the name in double quotes, for example, "PRODUCT"."LONG\_DESCRIPTION".

*qdr*: The dimension member being given an attribute value in the form of a qualified data reference, such as "PRODUCT"='OPT MOUSE'.

*attribute\_value*: The value of the attribute, such as 'Optical Mouse'.

- FOR *dimension\_clause* *measure\_clause* BUILD (*commands*)

Restricts the build to particular measures and dimension values, using the following arguments. See "[FOR Clause Example](#)".

– *dimension\_clause*:

*dimension* ALL | NONE | WHERE *condition* | LEVELS (*level* [, *level*...])

*dimension* is the name of a dimension of the cube.

ALL sets the dimension status to all members before executing the list of commands.

NONE loads values for no dimension members.

WHERE loads values for those dimension members that match the condition.

LEVELS loads values for dimension members in the named levels.

*level* is a level of the named dimension.

– *measure\_clause*:

MEASURES (*measure* [, *measure*...])

*measure* is the name of a measure in the cube.

– *commands*: Any of the other USING commands.

- LOAD [SYNCH | NO SYNCH | RETAIN] [PRUNE | PARALLEL | SERIAL] [WHERE *condition*]

Loads data into the dimension or cube.

– WHERE limits the load to those values in the mapped relational table that match *condition*.

– *condition* is a valid predicate based on the columns of the mapped table. See the "[Examples](#)".

These optional arguments apply only to dimensions:

- **SYNCH** matches the dimension keys to the relational data source. (Default)
- **NO SYNCH** loads new dimension keys but does not delete old keys.

If the parent of a dimension key has changed in the relational data source, this option allows the load to change the parent/child relation in the analytic workspace.

- **RETAIN** loads new dimension keys but does not delete old keys.

This option does not allow the parent of a dimension key to change. If the parent has changed, the load rejects the record. The rejection generates an error in the rejected records log, if the log is enabled.

These optional arguments apply only to cubes:

- **PRUNE**: Runs a full table scan on the fact table to determine which partitions to load. For example, if a cube is partitioned by month and the fact table has values only for the last two months, then jobs are only started to load the partitions for the last two months.
- **PARALLEL**: Each partition is loaded separately. (Default)
- **SERIAL**: All partitions are loaded in one **SELECT** statement.
- **MODEL** model\_name [**PARALLEL** | **SERIAL**]

Executes a model previously created for the cube. It accepts these arguments:

- **PARALLEL**: The model runs separately on each partition.
- **SERIAL**: The model runs on all cubes at the same time. (Default)
- **SET**
- **SOLVE** [**PARALLEL** | **SERIAL**]

Supports write-back to the cube using the syntax described in "[SCRIPT Parameter: USING Clause: SET command](#)". (Cubes only)

Aggregates the cube using the rules defined for the cube, including the aggregation operator and the precompute specifications. (Cubes only)

It accepts these arguments:

- **PARALLEL**: Each partition is solved separately. (Default)
- **SERIAL**: All partitions are solved at the same time.

### SCRIPT Parameter: USING Clause: AGGREGATE command

The **AGGREGATE** command in a script specifies the aggregation rules for one or more measures.

#### Note:

The **AGGREGATE** command is available only for uncompressed cubes.

**AGGREGATE** has the following syntax:

```
{ AGGREGATE USING MEASURE
  WHEN measure1 THEN operator1
  WHEN measure2 THEN operator2...
```

```

        ELSE default_operator
    |
    [AGGREGATE USING] operator_clause }
processing_options
OVER { ALL | dimension | dimension HIERARCHIES (hierarchy)}

```

### USING MEASURE Clause

This clause enables you to specify different aggregation operators for different measures in the cube.

#### Operator Clause

The `operator_clause` has this syntax:

```
operator(WEIGHTBY expression | SCALEBY expression)
```

**WEIGHTBY** multiplies each data value by an expression before aggregation.

**SCALEBY** adds the value of an expression to each data value before aggregation.

**Table 45-3 Aggregation Operators**

| Operator       | Option                | Description                                                                                                                                                                                                                                                                  |
|----------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVG            | WEIGHTBY              | Adds data values, then divides the sum by the number of data values that were added together.                                                                                                                                                                                |
| FIRST          | WEIGHTBY              | The first real data value.                                                                                                                                                                                                                                                   |
| HIER_AVG       | WEIGHTBY              | Adds data values, then divides the sum by the number of the children in the dimension hierarchy. Unlike AVERAGE, which counts only non-NA children, HAVERAGE counts all of the logical children of a parent, regardless of whether each child does or does not have a value. |
| HIER_FIRST     | WEIGHTBY              | The first data value in the hierarchy, even when that value is NA.                                                                                                                                                                                                           |
| HIER_LAST      | WEIGHTBY              | The last data value in the hierarchy, even when that value is NA.                                                                                                                                                                                                            |
| LAST           | WEIGHTBY              | The last real data value.                                                                                                                                                                                                                                                    |
| MAX            | WEIGHTBY              | The largest data value among the children of each parent.                                                                                                                                                                                                                    |
| MIN            | WEIGHTBY              | The smallest data value among the children of each parent.                                                                                                                                                                                                                   |
| NO AGGREGATION | No option             | Do not aggregate the values of the dimension or dimensions. Leave all aggregated values as NA.                                                                                                                                                                               |
| SUM            | SCALEBY  <br>WEIGHTBY | Adds data values. (Default)                                                                                                                                                                                                                                                  |

### Processing Options

You can specify these processing options for aggregation:

- (ALLOW | DISALLOW) OVERFLOW

Specifies whether to allow decimal overflow, which occurs when the result of a calculation is very large and can no longer be represented by the exponent portion of the numerical representation.

- **ALLOW:** A calculation that generates overflow executes without error and produces null results. (Default)

- **DISALLOW:** A calculation involving overflow stops executing and generates an error message.
- (ALLOW | DISALLOW) DIVISION BY ZERO  
Specifies whether to allow division by zero.
  - **ALLOW:** A calculation involving division by zero executes without error but returns a null value. (Default)
  - **DISALLOW:** A calculation involving division by zero stops executing and generates an error message.
- (CONSIDER | IGNORE) NULLS  
Specifies whether nulls are included in the calculations.
  - **CONSIDER:** Nulls are included in the calculations. A calculation that includes a null value returns a null value.
  - **IGNORE:** Only actual data values are used in calculations. Nulls are treated as if they do not exist. (Default)
- MAINTAIN COUNT  
Stores an up-to-date count of the number of dimension members for use in calculating averages. Omit this option to count the members on the fly.

#### SCRIPT Parameter: USING Clause: SET command

The **SET** command in a script assigns values to one or more cells in a stored measure. It has this syntax:

```
SET target = expression
```

*Where:*

*target* is a a measure or a qualified data reference.

*expression* returns values of the appropriate datatype for *target*.

#### Qualified Data References

Qualified data references (QDRs) limit a dimensional object to a single member in one or more dimensions for the duration of a query.

A QDR has the following syntax:

```
expression [ { dimension = member } [ , { dimension = member } ... ] ]
```

*Where:*

*expression* is a dimensional expression, typically the name of a measure.

*dimension* is a primary dimension of expression.

*member* is a value of dimension.

The outside square brackets shown in bold are literal syntax elements; they do not indicate an optional argument. The inside square brackets shown in regular text delimit an optional argument and are not syntax elements.

This example returns Sales values for calendar year 2007:

```
global.sales[global.time = 'CY2007']
```

The next example returns Sales values only for the United States in calendar year 2007:

```
sales[customer = 'US', time = 'CY2007']
```

See the Examples for qualified data references in SET commands.

## Usage Notes

### Build Methods

The **C**, **S**, and **?** methods always succeed and can be used on any cube.

The **F** and **P** methods require that the cube have a materialized view that was created as a fast or a rewrite materialized view.

### Parallelism

Partitioned cubes can be loaded and aggregated in parallel processes. For example, a cube with five partitions can use up to five processes. Dimensions are always loaded serially.

The number of parallel processes actually allocated by a build is controlled by the smallest of these factors:

- Number of cubes in the build and the number of partitions in each cube.
- Setting of the **PARALLELISM** argument of the **BUILD** procedure.
- Setting of the **JOB\_QUEUE\_PROCESSES** database initialization parameter.

Suppose **UNITS\_CUBE** has 12 partitions, **PARALLELISM** is set to 10, and **JOB\_QUEUE\_PROCESSES** is set to 4. OLAP uses four processes, which appear as slave processes in the build log.

The SQL engine may allocate additional processes when the **PARALLEL\_DEGREE\_POLICY** database initialization parameter is set to **AUTO** or **LIMITED**. For example, if OLAP allocates four processes, the SQL engine might determine that two of those processes should be done by four processes instead, for a total of six processes.

### Build Logs

OLAP generates three logs that provide diagnostic information about builds:

- Cube build log
- Rejected records log
- Cube dimension compile log

Analytic Workspace Manager creates these logs automatically as tables in the same schema as the analytic workspace. If you do not use Analytic Workspace Manager, you can create and manage the logs in PL/SQL using the **DBMS\_CUBE\_LOG** package.

You can also create the cube log file by running `$ORACLE_HOME/olap/admin/utlolarlog.sql`. This script creates three additional views:

- **CUBE\_BUILD\_LATEST**: Returns rows only from the last build.
- **CUBE\_BUILD\_REPORT**: Returns one row for each command with elapsed times.
- **CUBE\_BUILD\_REPORT\_LATEST**: Returns a report like **CUBE\_BUILD\_REPORT** only from the last build.

This report shows a successfully completed build of the objects in the GLOBAL analytic workspace, which has four dimensions and two cubes.

```
SELECT command, status, build_object, build_object_type type
FROM cube_build_report_latest;
```

| COMMAND                   | STATUS    | BUILD_OBJECT | TYPE      |
|---------------------------|-----------|--------------|-----------|
| -----                     | -----     | -----        | -----     |
| BUILD                     | COMPLETED |              | BUILD     |
| FREEZE                    | COMPLETED |              | BUILD     |
| LOAD NO SYNCH             | COMPLETED | CHANNEL      | DIMENSION |
| COMPILE                   | COMPLETED | CHANNEL      | DIMENSION |
| UPDATE/COMMIT             | COMPLETED | CHANNEL      | DIMENSION |
| LOAD NO SYNCH             | COMPLETED | CUSTOMER     | DIMENSION |
| COMPILE                   | COMPLETED | CUSTOMER     | DIMENSION |
| UPDATE/COMMIT             | COMPLETED | CUSTOMER     | DIMENSION |
| LOAD NO SYNCH             | COMPLETED | PRODUCT      | DIMENSION |
| COMPILE                   | COMPLETED | PRODUCT      | DIMENSION |
| UPDATE/COMMIT             | COMPLETED | PRODUCT      | DIMENSION |
| LOAD NO SYNCH             | COMPLETED | TIME         | DIMENSION |
| COMPILE                   | COMPLETED | TIME         | DIMENSION |
| UPDATE/COMMIT             | COMPLETED | TIME         | DIMENSION |
| COMPILE AGGMAP            | COMPLETED | PRICE_CUBE   | CUBE      |
| UPDATE/COMMIT             | COMPLETED | PRICE_CUBE   | CUBE      |
| COMPILE AGGMAP            | COMPLETED | UNITS_CUBE   | CUBE      |
| UPDATE/COMMIT             | COMPLETED | UNITS_CUBE   | CUBE      |
| DBMS_SCHEDULER.CREATE_JOB | COMPLETED | PRICE_CUBE   | CUBE      |
| DBMS_SCHEDULER.CREATE_JOB | COMPLETED | UNITS_CUBE   | CUBE      |
| BUILD                     | COMPLETED |              | BUILD     |
| LOAD                      | COMPLETED | PRICE_CUBE   | CUBE      |
| SOLVE                     | COMPLETED | PRICE_CUBE   | CUBE      |
| UPDATE/COMMIT             | COMPLETED | PRICE_CUBE   | CUBE      |
| BUILD                     | COMPLETED |              | BUILD     |
| LOAD                      | COMPLETED | UNITS_CUBE   | CUBE      |
| SOLVE                     | COMPLETED | UNITS_CUBE   | CUBE      |
| UPDATE/COMMIT             | COMPLETED | UNITS_CUBE   | CUBE      |
| ANALYZE                   | COMPLETED | PRICE_CUBE   | CUBE      |
| ANALYZE                   | COMPLETED | UNITS_CUBE   | CUBE      |
| THAW                      | COMPLETED |              | BUILD     |

31 rows selected.

## Examples

This example uses the default parameters to build UNITS\_CUBE.

```
EXECUTE DBMS_CUBE.BUILD('GLOBAL.UNITS_CUBE');
```

The next example builds UNITS\_CUBE and explicitly builds two of its dimensions, TIME and CHANNEL. The dimensions use the complete (C) method, and the cube uses the fast solve (S) method.

```
BEGIN
  DBMS_CUBE.BUILD(
    script=>'GLOBAL."TIME", GLOBAL.CHANNEL, GLOBAL.UNITS_CUBE',
    method=>'CCS',
    parallelism=>2);
END;
/
```

The following example loads only the selection of data identified by the WHERE clause:

```
BEGIN
  DBMS_CUBE.BUILD(q'!
    GLOBAL."TIME",
    GLOBAL.CHANNEL,
    GLOBAL.CUSTOMER,
    GLOBAL.PRODUCT,
    GLOBAL.UNITS_CUBE USING (LOAD NO SYNCH
      WHERE UNITS_FACT.MONTH_ID LIKE '2006%'
      AND UNITS_FACT.SALES > 5000)!');
END;
/
```

### FOR Clause Example

In this example, the Time dimension is partitioned by calendar year, and DBMS\_CUBE builds only the partition identified by CY2006. The HIER\_ANCESTOR is an analytic function in the OLAP expression syntax.

```
BEGIN
  dbms_cube.build(q'!
    UNITS_CUBE USING
    (
      FOR "TIME"
        WHERE HIER_ANCESTOR(WITHIN "TIME".CALENDAR LEVEL "TIME".CALENDAR_YEAR) = 'CY2006'
        BUILD (LOAD, SOLVE)
    )!',
    parallelism=>1);
END;
/
```

The next example uses a FOR clause to limit the build to the SALES measure in 2006. All objects are built using the complete (c) method.

```
BEGIN
  DBMS_CUBE.BUILD(
    script => '
    GLOBAL."TIME",
    GLOBAL.CHANNEL,
    GLOBAL.CUSTOMER,
    GLOBAL.PRODUCT,
    GLOBAL.UNITS_CUBE USING
    (
      FOR MEASURES(GLOBAL.UNITS_CUBE.SALES)
        BUILD(LOAD NO SYNCH WHERE GLOBAL.UNITS_FACT.MONTH_ID LIKE ''2006%'')
    )',
    method => 'C',
    parallelism => 2);
END;
/
```

### Write-Back Examples

The following examples show various use of the SET command in a USING clause.

This example sets Sales Target to Sales increased by 5%:

```
DBMS_CUBE.BUILD('UNITS_CUBE USING(
  SET UNITS_CUBE.SALES_TARGET = UNITS_CUBE.SALES * 1.05, SOLVE)');
```

This example sets the price of the Deluxe Mouse in May 2007 to \$29.99:

```
DBMS_CUBE.BUILD('PRICE_CUBE USING(
  SET PRICE_CUBE.UNIT_PRICE["TIME"='2007.05', "PRODUCT"='DLX MOUSE']
  = 29.99, SOLVE)');
```

The next example contains two SET commands, but does not reaggregate the cube:

```
DBMS_CUBE.BUILD('PRICE_CUBE USING(
  SET PRICE_CUBE.UNIT_PRICE["TIME"='2006.12', "PRODUCT"='DLX MOUSE']
  = 29.49,
  SET PRICE_CUBE.UNIT_PRICE["TIME"='2007.05', "PRODUCT"='DLX MOUSE']
  = 29.99)');
```

### Dimension Maintenance Example

This script shows dimension maintenance. It adds a new dimension member named OPT MOUSE to all hierarchies, alters its position in the Primary hierarchy, assigns it a long description, then deletes it from the dimension.

```
BEGIN
dbms_output.put_line('Add optical mouse');
dbms_cube.build(q'!
  "PRODUCT" using (MERGE INTO ALL HIERARCHIES
    VALUES ('ITEM_OPT MOUSE', 'CLASS_SFT', "PRODUCT"."FAMILY"))
!');

dbms_output.put_line('Alter optical mouse');
dbms_cube.build(q'!
  "PRODUCT" using (UPDATE HIERARCHIES ("PRODUCT"."PRIMARY")
    SET PARENT = 'FAMILY_ACC', LEVEL = "PRODUCT"."ITEM"
    WHERE MEMBER = 'ITEM_OPT MOUSE')
!');

dbms_output.put_line('Provide attributes to optical mouse');
dbms_cube.build(q'!
  "PRODUCT" USING (SET "PRODUCT"."LONG_DESCRIPTION"["PRODUCT" = 'ITEM_OPT MOUSE']
    = CAST('Optical Mouse' AS VARCHAR2))
!');

dbms_output.put_line('Delete optical mouse');
dbms_cube.build(q'!
  "PRODUCT" USING (DELETE FROM DIMENSION WHERE MEMBER='ITEM_OPT MOUSE')
!');

END;
/
```

### OLAP DML Example

This example uses the OLAP DML to add comments to the cube build log:

```
BEGIN
DBMS_CUBE.BUILD(q'!
  global.units_cube USING (
    EXECUTE OLAP DML 'SHOW STATLEN(units_cube_prt_list)' PARALLEL,
    EXECUTE OLAP DML 'SHOW LIMIT(units_cube_prt_list KEEP ALL)' PARALLEL,
    EXECUTE OLAP DML 'SHOW STATLEN(time)' parallel,
    EXECUTE OLAP DML 'SHOW LIMIT(time KEEP time_levelrel 'CALENDAR_YEAR')' parallel)!',
    parallelism=>2,
    add_dimensions=>false);
END;
/
```

This query shows the comments in the cube build log:

```
SELECT partition, slave_number, TO_CHAR(output) output
FROM cube_build_log
WHERE command = 'OLAP DML'
AND status = 'COMPLETED'
ORDER BY slave_number, time;
```

| PARTITION  | SLAVE_NUMBER | OUTPUT                                                                                                                                     |
|------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| P10:CY2007 | 1            | <OLAPDMLExpression<br>Expression="TO_CHAR(statlen(units_cube_prt_list))"<br>Value="1"/>                                                    |
| P10:CY2007 | 1            | <OLAPDMLExpression<br>Expression="TO_CHAR(limit(units_cube_prt_list keep al<br>1))"<br>Value="P10"/>                                       |
| P10:CY2007 | 1            | <OLAPDMLExpression<br>Expression="TO_CHAR(statlen(time))"<br>Value="17"/>                                                                  |
| P10:CY2007 | 1            | <OLAPDMLExpression<br>Expression="TO_CHAR(limit(time keep time_levelrel &ap<br>os;CALENDAR_YEAR&apos;))"<br>Value="CALENDAR_YEAR_CY2007"/> |
| P9:CY2006  | 2            | <OLAPDMLExpression<br>Expression="TO_CHAR(statlen(units_cube_prt_list))"<br>Value="1"/>                                                    |
| P9:CY2006  | 2            | <OLAPDMLExpression<br>Expression="TO_CHAR(limit(units_cube_prt_list keep al<br>1))"<br>Value="P9"/>                                        |
| P9:CY2006  | 2            | <OLAPDMLExpression<br>Expression="TO_CHAR(statlen(time))"<br>Value="17"/>                                                                  |
| .          | .            | .                                                                                                                                          |

## 45.4.2 CREATE\_EXPORT\_OPTIONS Procedure

This procedure creates an input XML document that describes processing options for the EXPORT\_XML Procedure and the EXPORT\_XML\_TO\_FILE Procedure.

### Syntax

```
DBMS_CUBE.CREATE_EXPORT_OPTIONS (
    out_options_xml      IN/OUT  CLOB,
    target_version        IN      VARCHAR2  DEFAULT NULL,
    suppress_owner        IN      BOOLEAN    DEFAULT FALSE,
    suppress_namespace    IN      BOOLEAN    DEFAULT FALSE,
    preserve_table_owners IN      BOOLEAN    DEFAULT FALSE,
    metadata_changes      IN      CLOB       DEFAULT NULL);
```

## Parameters

**Table 45-4 CREATE\_EXPORT\_OPTIONS Procedure Parameters**

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| out_options_xml       | Contains the generated XML document, which can be passed into the options_xml parameter of the <a href="#">EXPORT_XML Procedure</a> .                                                                                                                                                                                                                                                                                                                                                                                                       |
| target_version        | Specifies the version of Oracle Database in which the XML document generated by EXPORT_XML or EXPORT_XML_TO_FILE will be imported. You can specify two to five digits, such as 12.1 or 12.1.0.1.0. This parameter defaults to the current database version, and so can typically be omitted.                                                                                                                                                                                                                                                |
| suppress_owner        | Controls the use of the Owner attribute in XML elements and the owner qualifier in object names. Enter <code>True</code> to drop the owner from the XML, or enter <code>False</code> to retain it. Enter <code>True</code> if you plan to import the exported metadata into a different schema.                                                                                                                                                                                                                                             |
| suppress_namespace    | Controls the use of Namespace attributes in XML elements and the namespace qualifier in object names. Enter <code>True</code> to drop the namespace from the XML, or enter <code>False</code> to retain it (default). Enter <code>True</code> when upgrading to Oracle OLAP 12c metadata.<br><br>Namespaces allow objects created in Oracle 10g to coexist with objects created in Oracle 12c. You cannot set or change namespaces.                                                                                                         |
| preserve_table_owners | Controls the use of the owner in qualifying table names in the mapping elements, such as GLOBAL.UNITS_HISTORY_FACT instead of UNITS_HISTORY_FACT. Enter <code>True</code> to retain the table owner, or enter <code>False</code> to default to the current schema for table mappings. If you plan to import the exported metadata to a different schema, you must set this option to <code>True</code> to load data from tables and views in the original schema, unless the destination schema has its own copies of the tables and views. |
| metadata_changes      | Contains an 12c XML description of an object that overwrites the exported object description. The XML document must contain all parent XML elements of the modified element with the attributes needed to uniquely identify them. Use the Name attribute if it exists. See the Examples.                                                                                                                                                                                                                                                    |

## Examples

The following example generates an XML document of export options:

```
DECLARE
    optionsClob CLOB;

BEGIN
    dbms_lob.createtemporary(optionsClob, false, dbms_lob.CALL);
    dbms_cube.create_export_options(out_options_xml=>optionsClob,
    suppress_namespace=>TRUE);
    dbms_output.put_line(optionsClob);
END;
/
```

The DBMS\_OUTPUT.PUT\_LINE procedure displays this XML document (formatted for readability):

```
<?xml version="1.0"?>
<Export TargetVersion="12.1.0.1">
  <ExportOptions>
```

```

    <Option Name="SuppressOwner" Value="FALSE"/>
    <Option Name="SuppressNamespace" Value="TRUE"/>
    <Option Name="PreserveTableOwners" Value="FALSE"/>
  </ExportOptions>
</Export>

```

The next example generates an XML document with a metadata change to the mapping of the American long description attribute of the CHANNEL dimension.

```

DECLARE
  importClob      clob;
  exportClob      clob;
  overClob        clob;
  exportOptClob   clob;
  importOptClob   clob;

BEGIN
  dbms_lob.createtemporary(overClob, TRUE);
  dbms_lob.open(overClob, DBMS_LOB.LOB_READWRITE);
  dbms_lob.writeappend(overClob,58, '<Metadata Version="1.3"
MinimumDatabaseVersion="12.1.0.1">');
  dbms_lob.writeappend(overClob,34, '<StandardDimension Name="CHANNEL">');
  dbms_lob.writeappend(overClob,75, '<Description Type="Description" Language="AMERICAN"
Value="Sales Channel"/>');
  dbms_lob.writeappend(overClob,20, '</StandardDimension>');
  dbms_lob.writeappend(overClob,11, '</Metadata>');
  dbms_lob.close(overClob);

  -- Enable Oracle Database 12c Release 1 (12.1) clients to access 10g metadata
  dbms_cube.initialize_cube_upgrade;

  -- Create a CLOB containing the export options
  dbms_lob.createtemporary(exportOptClob, TRUE);
  dbms_cube.create_export_options(out_options_xml=>exportOptClob,
suppress_namespace=>TRUE, metadata_changes=>overClob);

  -- Create a CLOB containing the import options
  dbms_lob.createtemporary(importOptClob, TRUE);
  dbms_cube.create_import_options(out_options_xml=>importOptClob, rename_table =>
'MY_OBJECT_MAP');

  -- Create CLOBs for the metadata
  dbms_lob.createtemporary(importClob, TRUE);
  dbms_lob.createtemporary(exportClob, TRUE);

  -- Export metadata from a 10g analytic workspace to a CLOB
  dbms_cube.export_xml(object_ids=>'GLOBAL_AW', options_xml=>exportOptClob,
out_xml=>exportClob);

  -- Import metadata from the CLOB
  dbms_cube.import_xml(in_xml => exportClob, options_xml=>importOptClob,
out_xml=>importClob);

  -- Load and aggregate the data
  dbms_cube.build(script=>'UNITS_CUBE, PRICE_AND_COST_CUBE');

END;
/

```

The following is the content of exportClob (formatting added for readability). The XML document changes the description of Channel to Sales Channel.

```
<Metadata Version="1.3" MinimumDatabaseVersion="12.1.0.1">
  <StandardDimension Name="CHANNEL">
    <Description Type="Description" Language="AMERICAN" Value="Sales Channel"/>
  </StandardDimension>
</Metadata>
```

### Related Topics

- [EXPORT\\_XML Procedure](#)  
This procedure writes OLAP metadata to a CLOB.
- [EXPORT\\_XML\\_TO\\_FILE Procedure](#)  
This procedure exports OLAP metadata to a file. This file can be imported into a new or existing analytic workspace using the [IMPORT\\_XML](#) procedure. In this way, you can create a copy of the analytic workspace in another schema or database.

## 45.4.3 CREATE\_IMPORT\_OPTIONS Procedure

This procedure creates an input XML document that describes processing options for the [IMPORT\\_XML](#) Procedure.

### Syntax

```
DBMS_CUBE.CREATE_IMPORT_OPTIONS (
    out_options_xml  IN/OUT  CLOB,
    validate_only    IN      BOOLEAN   DEFAULT FALSE,
    rename_table     IN      VARCHAR2  DEFAULT NULL);
```

### Parameters

**Table 45-5** CREATE\_IMPORT\_OPTIONS Procedure Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| out_options_xml | Contains the generated XML document, which can be passed to the options_xml parameter of the <a href="#">IMPORT_XML Procedure</a> .                                                                                                                                                                                  |
| validate_only   | TRUE causes the <a href="#">IMPORT_XML</a> procedure to validate the metadata described in the input file or the in_xml parameter, without committing the changes to the metadata.                                                                                                                                   |
| rename_table    | The name of a table identifying new names for the imported objects, in the form [schema_name].table_name. The <a href="#">IMPORT_XML</a> procedure creates objects using the names specified in the table instead of the ones specified in the XML document. See the Usage Notes for the format of the rename table. |

### Usage Notes

See the information about using a rename table in [DBMS\\_CUBE - Upgrading 10g Analytic Workspaces](#).

### Examples

This example specifies validation only and a rename table. For an example of the import CLOB being used in an import, see "[IMPORT\\_XML Procedure](#)".

```
DECLARE
importClob  clob;

BEGIN
```

```

dbms_lob.createtemporary(importClob, TRUE);

dbms_cube.create_import_options(out_options_xml => importClob, rename_table =>
'MY_OBJECT_MAP', validate_only => TRUE);

dbms_output.put_line(importClob);
END;
/

```

It generates the following XML document:

```

<?xml version="1.0"?>
<Import>
  <ImportOptions>
    <Option Name="ValidateOnly" Value="TRUE"/>
    <Option Name="RenameTable" Value="MY_OBJECT_MAP"/>
  </ImportOptions>
</Import>

```

### Related Topics

- [IMPORT\\_XML Procedure](#)  
This procedure creates, modifies, or drops an analytic workspace by using an XML template.

## 45.4.4 CREATE\_MVIEW Function

This function creates a cube materialized view from the definition of a relational materialized view.

### Syntax

```

DBMS_CUBE.CREATE_MVIEW (
    mvowner      IN  VARCHAR2,
    mvname       IN  VARCHAR2,
    sam_parameters IN CLOB  DEFAULT NULL)
RETURN VARCHAR2;

```

### Parameters

**Table 45-6 CREATE\_MVIEW Function Parameters**

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mvowner        | Owner of the relational materialized view.                                                                                                                                                                                                                                                                                                                                                    |
| mvname         | Name of the relational materialized view. For restrictions, see <a href="#">"Requirements for the Relational Materialized View"</a> .<br><br>A single cube materialized view can replace many of the relational materialized views for a table. Choose the materialized view that has the lowest levels of the dimension hierarchies that you want represented in the cube materialized view. |
| sam_parameters | Parameters in the form 'parameter1=value1, parameter2=value2,...'. See <a href="#">"SQL Aggregation Management Parameters"</a> .                                                                                                                                                                                                                                                              |

### SQL Aggregation Management Parameters

The `CREATE_MVIEW` and `DERIVE_FROM_MVIEW` functions use the SQL aggregation management (SAM) parameters described in [Table 45-7](#). Some parameters support the development of cubes with advanced analytics. Other parameters support the development of Java

applications. The default settings are appropriate for cube materialized views that are direct replacements for relational materialized views.

**Table 45-7 SQL Aggregation Management Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDTOPS            | <p>Adds a top level and a level member to every dimension hierarchy in the cube. If the associated relational dimension has no hierarchy, then a dimension hierarchy is created.</p> <p>TRUE: Creates levels named <code>ALL_dimension</code> with level members <code>All_dimension</code>. (Default)</p> <p>FALSE: Creates only the hierarchies and levels identified by the relational dimensions.</p>                                                                                                                 |
| ADDUNIQUEKEYPREFIX | <p>Controls the creation of dimension keys.</p> <p>TRUE: Creates cube dimension keys by concatenating the level name with the relational dimension key. This practice assures that the dimension keys are unique across all levels, such as <code>CITY_NEW_YORK</code> and <code>STATE_NEW_YORK</code>. (Default)</p> <p>FALSE: Uses the relational dimension keys as cube dimension keys.</p>                                                                                                                            |
| ATRMAPTTYPE        | <p>Specifies whether attributes are mapped by hierarchy levels, dimension levels, or both.</p> <p>HIER_LEVEL: Maps attributes to the levels of a particular dimension hierarchy. (Default)</p> <p>DIM_LEVEL: Maps attributes to the levels of the dimension regardless of hierarchy.</p> <p>BOTH: Maps attributes to both dimension and hierarchy levels.</p> <p>AUTO: Maps attributes to the levels of the dimension for a star schema and to the levels of a particular dimension hierarchy for a snowflake schema.</p> |
| AWNAME             | <p>Provides the name of the analytic workspace that owns the cube. Choose a simple database object name of 1 to 30 bytes. The default name is <code>fact_tablename_AWn</code>.</p>                                                                                                                                                                                                                                                                                                                                        |
| BUILD              | <p>Specifies whether a data refresh will immediately follow creation of the cube materialized view.</p> <p>IMMEDIATE: Refreshes immediately.</p> <p>DEFERRED: Does not perform a data refresh. (Default)</p> <p><b>Note:</b> Only the <code>CREATE_MVIEW</code> function uses this parameter.</p>                                                                                                                                                                                                                         |

**Table 45-7 (Cont.) SQL Aggregation Management Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CUBEMVOPTION    | <p>Controls validation and creation of a cube materialized view. Regardless of this setting, the function creates an analytic workspace containing a cube and its related cube dimensions.</p> <p><b>COMPLETE_REFRESH:</b> Creates a complete refresh cube materialized view (full update).</p> <p><b>FAST_REFRESH:</b> Creates a fast refresh materialized view (incremental update).</p> <p><b>REWRITE_READY:</b> Runs validation checks for a rewrite cube materialized view, but does not create it.</p> <p><b>REWRITE:</b> Creates a rewrite cube materialized view.</p> <p><b>REWRITE_WITH_ATTRIBUTES:</b> Creates a rewrite cube materialized view that includes columns with dimension attributes, resulting in faster query response times. (Default)</p> <p><b>Note:</b> <i>The following settings do not create a cube materialized view. Use Analytic Workspace Manager to drop an analytic workspace that does not have a cube materialized view. You can use the <code>DROP_MVIEW</code> procedure to delete an analytic workspace only when it supports a cube materialized view.</i></p> <p><b>NONE:</b> Does not create a cube materialized view.</p> <p><b>COMPLETE_REFRESH_READY:</b> Runs validation checks for a complete refresh cube materialized view, but does not create it.</p> <p><b>FAST_REFRESH_READY:</b> Runs validation checks for fast refresh, but does not create the cube materialized view.</p> |
| CUBENAME        | <p>Provides the name of the cube derived from the relational materialized view. Choose simple database object name of 1 to 30 bytes. The default name is <i>fact_tablename_Cn</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DIMJAVABINDVARS | <p>Supports access by Java programs to the XML document.</p> <p><b>TRUE:</b> Generates an XML template that uses Java bind variable notation for the names of dimensions. No XML validation is performed. You cannot use the <code>IMPORT_XML</code> procedure to create a cube using this template.</p> <p><b>FALSE:</b> Generates an XML template that does not support Java bind variables. (Default)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DISABLEQRW      | <p>Controls disabling of query rewrite on the source relational materialized view.</p> <p><b>TRUE:</b> Issues an <code>ALTER MATERIALIZED VIEW mview_name DISABLE QUERY REWRITE</code> command.</p> <p><b>FALSE:</b> No action.</p> <p><b>Note:</b> Only the <code>CREATE_MVIEW</code> function with <code>BUILD=IMMEDIATE</code> uses this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| EXPORTXML       | <p>Exports the XML that defines the dimensional objects to a file, which you specify as <i>dir/filename</i>. Both the directory and the file name are case sensitive.</p> <p><i>dir:</i> Name of a database directory.</p> <p><i>filename:</i> The name of the file, typically given an XML filename extension.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 45-7 (Cont.) SQL Aggregation Management Parameters**

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>FILTERPARTITIONANCESTORLEVELS</code> | <p>Controls the generation of aggregate values above the partitioning level of a partitioned cube.</p> <p><b>TRUE:</b> Removes levels above the partitioning level from the cube. Requests for summary values above the partitioning level are solved by SQL.</p> <p><b>FALSE:</b> All levels are retained in the cube. Requests for summary values are solved by OLAP. (Default)</p>                                                                                                                                                                                                       |
| <code>LOGDEST</code>                       | <p>Directs and stores log messages. By default, the messages are not available.</p> <p><b>SERVEROUT:</b> Sends messages to server output (typically the screen), which is suitable when working interactively such as in SQL*Plus or SQL Developer.</p> <p><b>TRACEFILE:</b> Sends messages to the session trace file.</p>                                                                                                                                                                                                                                                                  |
| <code>PARTITIONOPTION</code>               | <p>Controls partitioning of the cube.</p> <p><b>NONE:</b> Prevents partitioning.</p> <p><b>DEFAULT:</b> Allows the Sparsity Advisor to determine whether partitioning is needed and how to partition the cube. (Default)</p> <p><b>FORCE:</b> Partitions the cube even when the Sparsity Advisor recommends against it. The Sparsity Advisor identifies the best dimension, hierarchy, and level to use for partitioning.</p> <p><i>dimension.hierarchy.level:</i> Partitions the cube using the specified dimension, hierarchy, and level.</p>                                             |
| <code>POPULATELINEAGE</code>               | <p>Controls the appearance of attributes in a cube materialized view.</p> <p><b>TRUE:</b> Includes all dimension attributes in the cube materialized view. (Default)</p> <p><b>FALSE:</b> Omits all dimension attributes from the cube materialized view.</p>                                                                                                                                                                                                                                                                                                                               |
| <code>PRECOMPUTE</code>                    | <p>Identifies a percentage of the data that is aggregated and stored. The remaining values are calculated as required by queries during the session.</p> <p><i>precompute_percentage[:precompute_top_percentage]</i></p> <p>Specify the top percentage for partitioned cubes. The default value is 35:0, which specifies precomputing 35% of the bottom partition and 0% of the top partition. If the cube is not partitioned, then the second number is ignored.</p>                                                                                                                       |
| <code>REMAPCOMPOSITEKEYS</code>            | <p>Controls how multicolumn keys are rendered in the cube.</p> <p><b>TRUE:</b> Creates a unique key attribute whose values are concatenated string expressions with an underscore between the column values. For example, the value <code>BOSTON_MA_USA</code> might be an expression produced from a multicolumn key composed of <code>CITY</code>, <code>STATE</code>, and <code>COUNTRY</code> columns. In addition, an attribute is created for each individual column to store the relational keys. (Default)</p> <p><b>FALSE:</b> Creates a unique key attribute for each column.</p> |

**Table 45-7 (Cont.) SQL Aggregation Management Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RENDERINGMODE   | Controls whether a loss in fidelity between the relational materialized view and the cube materialized view results in a warning message or an exception. See <a href="#">"Requirements for the Relational Materialized View"</a> .<br>LOOSE: Losses are noted in the optional logs generated by the <a href="#">CREATE_MVIEW Function</a> and the <a href="#">DERIVE_FROM_MVIEW Function</a> . No exceptions are raised. (Default)<br>STRICT: Any loss in fidelity raises an exception so that no XML template is created. |
| SEEFILTERS      | Controls whether conditions in the WHERE clause of the relational materialized view's defining query are retained or ignored.<br>TRUE: Renders valid conditions in the XML template. (Default)<br>FALSE: Ignores all conditions.                                                                                                                                                                                                                                                                                            |
| UNIQUENAMES     | Controls whether top level dimensional objects have unique names. Cross namespace conflicts may occur because dimensional objects have different namespaces than relational objects.<br>TRUE: Modifies all relational names when they are rendered in the cube. (Default)<br>FALSE: Duplicates relational names in the cube unless a naming conflict is detected. In that case, a unique name is created.                                                                                                                   |
| UNKNOWNKEYASDIM | Controls handling of simple columns with no levels or hierarchies in the GROUP BY clause of the relational materialized view's defining query.<br>TRUE: Renders a simple column without a relational dimension as a cube dimension with no levels or hierarchies.<br>FALSE: Raises an exception when no relational dimension is found for the column. (Default)                                                                                                                                                             |
| VALIDATEXML     | Controls whether the generated XML document is validated.<br>TRUE: Validates the template using the <a href="#">VALIDATE_XML</a> procedure. (Default)<br>FALSE: No validation is done.                                                                                                                                                                                                                                                                                                                                      |

### Returns

The name of the cube materialized view created by the function.

### Usage Notes

See ["Using SQL Aggregation Management"](#)

### Examples

All examples for the SQL Aggregate Management subprograms use the sample Sales History schema, which is installed in Oracle Database with two relational materialized views:

[CAL\\_MONTH\\_SALES\\_MV](#) and [FWEEK\\_PSCAT\\_SALES\\_MV](#).

The following script creates a cube materialized view using [CAL\\_MONTH\\_SALES\\_MV](#) as the relational materialized view. It uses all default options.

```
SET serverout ON format wrapped
```

```
DECLARE  
    salesaw varchar2(30);
```

```
BEGIN
    salesaw := dbms_cube.create_mview('SH', 'CAL_MONTH_SALES_MV');
END;
/
```

The next example sets several parameters for creating a cube materialized view from FWEEK\_PSCAT\_SALES\_MV. These parameters change the cube materialized view in the following ways:

- **ADDTOPS:** Adds a top level consisting of a single value to the hierarchies. All of the dimensions in Sales History have a top level already.
- **PRECOMPUTE:** Changes the percentage of materialized aggregates from 35:0 to 40:10.
- **EXPORTXML:** Creates a text file for the XML document.
- **BUILD:** Performs a data refresh.

```
DECLARE
    salescubemv    varchar2(30);
    sam_param      clob := 'ADDTOPS=FALSE,
                           PRECOMPUTE=40:10,
                           EXPORTXML=WORK_DIR/sales.xml,
                           BUILD=IMMEDIATE';

BEGIN
    salescubemv := dbms_cube.create_mview('SH', 'FWEEK_PSCAT_SALES_MV',
                                          sam_param);
END;
/
```

## 45.4.5 DERIVE\_FROM\_MVIEW Function

This function generates an XML template that defines a cube with materialized view capabilities, using the information derived from an existing relational materialized view.

### Syntax

```
DBMS_CUBE.DERIVE_FROM_MVIEW (
    mvowner      IN  VARCHAR2,
    mvname       IN  VARCHAR2,
    sam_parameters IN CLOB  DEFAULT NULL)
RETURN CLOB;
```

### Parameters

**Table 45-8 DERIVE\_FROM\_MVIEW Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mvowner   | Owner of the relational materialized view.                                                                                                                                                                                                                                                                                                                                                          |
| mvname    | <p>Name of the relational materialized view. For restrictions, see <a href="#">"Requirements for the Relational Materialized View"</a>.</p> <p>A single cube materialized view can replace many of the relational materialized views for a table. Choose the materialized view that has the lowest levels of the dimension hierarchies that you want represented in the cube materialized view.</p> |

**Table 45-8 (Cont.) DERIVE\_FROM\_MVIEW Function Parameters**

| Parameter                   | Description                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sam_parameters</code> | Optional list of parameters in the form ' <i>parameter1=value1, parameter2=value2,...</i> '. See " <a href="#">SQL Aggregation Management Parameters</a> ". |

### Returns

An XML template that defines an analytic workspace containing a cube enabled as a materialized view.

### Usage Notes

To create a cube materialized view from an XML template, use the `IMPORT_XML` procedure. Then use the `REFRESH_MVIEW` procedure to refresh the cube materialized view with data.

See "[Using SQL Aggregation Management](#)".

### Examples

The following example generates an XML template named `sales_cube.xml` from the `CAL_MONTH_SALES_MV` relational materialized view in the `SH` schema.

```
DECLARE
    salescubexml  clob := null;
    sam_param     clob := 'exportXML=WORK_DIR/sales_cube.xml';

BEGIN
    salescubexml := dbms_cube.derive_from_mview('SH', 'CAL_MONTH_SALES_MV',
    sam_param);
END;
/
```

## 45.4.6 DROP\_MVIEW Procedure

This procedure drops a cube materialized view and all associated objects from the database. These objects include the dimension materialized views, cubes, cube dimensions, levels, hierarchies, and the analytic workspace.

### Syntax

```
DBMS_CUBE.DROP_MVIEW (
    mvowner      IN  VARCHAR2,
    mvname       IN  VARCHAR2,
    sam_parameters IN CLOB  DEFAULT NULL);
```

### Parameters

**Table 45-9 DROP\_MVIEW Procedure Parameters**

| Parameter            | Description                         |
|----------------------|-------------------------------------|
| <code>mvowner</code> | Owner of the cube materialized view |
| <code>mvname</code>  | Name of the cube materialized view  |

**Table 45-9 (Cont.) DROP\_MVIEW Procedure Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sam_parameters</code> | <p>EXPORTXML: Exports the XML that drops the dimensional objects to a file, which you specify as <i>dir/filename</i>. Both the directory and the file name are case sensitive.</p> <p><i>dir</i>: Name of a database directory.</p> <p><i>filename</i>: The name of the file, typically given an XML filename extension.</p> |

### Usage Notes

Use this procedure to drop a cube materialized view that you created using the `CREATE_MVIEW` and `DERIVE_FROM_MVIEW` functions. If you make modifications to the cubes or dimensions, then `DROP_MVIEW` may not be able to drop the cube materialized view.

Some of the `CUBEMVOPTION` parameters used by the `CREATE_MVIEW` and `DERIVE_FROM_MVIEW` functions do not create a materialized view. Use Analytic Workspace Manager to drop the analytic workspace, cubes, and cube dimensions.

If you use the `EXPORTXML` parameter, then you can use the XML document to drop the cube materialized view, after you re-create it. Use the `IMPORT_XML` procedure.

See ["Using SQL Aggregation Management"](#).

### Examples

The current schema has four materialized views. `CB$CAL_MONTH_SALES` is a cube materialized view for the `SALES` table. `CB$TIMES_DIM_D1_CAL_ROLLUP` is a cube dimension materialized view for the `TIMES_DIM` dimension on the `TIMES` dimension table. The others are relational materialized views.

```
SELECT mview_name FROM user_mviews;
```

```
MVIEW_NAME
-----
CB$CAL_MONTH_SALES
CB$TIMES_DIM_D1_CAL_ROLLUP
CAL_MONTH_SALES_MV
FWEEK_PSCAT_SALES_MV
```

The following command drops both `CB$CAL_MONTH_SALES` and `CB$TIMES_DIM_D1_CAL_ROLLUP`.

```
EXECUTE dbms_cube.drop_mview('SH', 'CB$CAL_MONTH_SALES');
```

```
Dropped cube organized materialized view "SH"."CAL_MONTH_SALES"
including container analytic workspace "SH"."CAL_MONTH_SALES_AW"
at 20130213 16:31:40.056.
```

This query against the data dictionary confirms that the materialized views have been dropped.

```
SELECT mview_name FROM user_mviews;
```

```
MVIEW_NAME
-----
CAL_MONTH_SALES_MV
FWEEK_PSCAT_SALES_MV
```

# 45.4.7 EXPORT\_XML Procedure

This procedure writes OLAP metadata to a CLOB.

## Syntax

```
DBMS_CUBE.EXPORT_XML
(object_ids          IN      VARCHAR2,
 out_xml            IN/OUT  CLOB;

DBMS_CUBE.EXPORT_XML
(object_ids          IN      VARCHAR2,
 options_xml        IN      CLOB,
 out_xml            IN/OUT  CLOB;

DBMS_CUBE.EXPORT_XML
(object_ids          IN      VARCHAR2,
 options_dirname     IN      VARCHAR2,
 options_filename    IN      VARCHAR2,
 out_xml            IN/OUT  CLOB;
```

## Parameters

Table 45-10 EXPORT\_XML Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_ids       | Any of these identifiers. <ul style="list-style-type: none"><li>• The name of a schema, such as GLOBAL.</li><li>• The fully qualified name of an analytic workspace in the form <i>owner.aw_name.AW</i>, such as GLOBAL.GLOBAL.AW.</li><li>• Cube</li><li>• Dimension</li><li>• Named build process</li><li>• Measure folder</li></ul> You can specify multiple objects by separating the names with commas.<br><b>Note:</b> When exporting an individual object, be sure to export any objects required to reconstruct it. For example, when exporting a cube, you must also export the dimensions of the cube. |
| options_dirname  | The case-sensitive name of a database directory that contains <i>options_filename</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| options_filename | A file containing an XML document of export options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| options_xml      | A CLOB variable that contains an XML document of export options. Use the <a href="#">CREATE_EXPORT_OPTIONS Procedure</a> to generate this document.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| out_xml          | A CLOB variable that will store the XML document of OLAP metadata for the objects listed in <i>object_ids</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Export Options

The default settings for the export options are appropriate in many cases, so you can omit the *options\_xml* parameter or the *options\_dirname* and *options\_filename* parameters. However, when upgrading Oracle OLAP 10g metadata to OLAP 12c, you must specify an XML document

that changes the default settings. This example changes all of the parameters from False to True; set them appropriately for your schema.

```
<?xml version="1.0"?>
<Export>
  <ExportOptions>
    <Option Name="SuppressNamespace" Value="True"/>
    <Option Name="SuppressOwner" Value="True"/>
    <Option Name="PreserveTableOwners" Value="True"/>
  </ExportOptions>
</Export>
```

You can create this XML document manually or by using the [CREATE\\_EXPORT\\_OPTIONS Procedure](#).

### Usage Notes

See "[DBMS\\_CUBE - Upgrading 10g Analytic Workspaces](#)".

### Example

For an example of using `EXPORT_XML` in an upgrade to the same schema, see "[DBMS\\_CUBE - Upgrading 10g Analytic Workspaces](#)".

The following PL/SQL script copies an OLAP 12c analytic workspace named `GLOBAL12` from the `GLOBAL_AW` schema to the `GLOBAL` schema. No upgrade is performed.

To upgrade into a different schema, change the example as follows:

- Call the `INITIALIZE_CUBE_UPGRADE` procedure.
- Call the `CREATE_EXPORT_OPTIONS` procedure with the additional parameter setting `SUPPRESS_NAMESPACE=>TRUE`.

The PL/SQL client must be connected to the database as `GLOBAL`. The `GLOBAL` user must have `SELECT` permissions on `GLOBAL_AW.AW$GLOBAL` and on all relational data sources.

```
BEGIN
  -- Create a CLOB for the export options
  dbms_lob.createtemporary(optionsClob, TRUE);
  dbms_cube.create_export_options(out_options_xml=>optionsClob, suppress_owner=>TRUE,
  preserve_table_owners=>TRUE);

  -- Create a CLOB for the XML template
  dbms_lob.createtemporary(exportClob, TRUE);

  -- Export metadata from an analytic workspace to a CLOB
  dbms_cube.export_xml(object_ids=>'GLOBAL_AW.GLOBAL12.AW', options_xml=>optionsClob,
  out_xml=>exportClob);

  -- Import metadata from the CLOB
  dbms_cube.import_xml(in_xml=>exportClob);

  -- Load and aggregate the data
  dbms_cube.build(script=>'GLOBAL.UNITS_CUBE, GLOBAL.PRICE_AND_COST_CUBE');

END;
/
```

## 45.4.8 EXPORT\_XML\_TO\_FILE Procedure

This procedure exports OLAP metadata to a file. This file can be imported into a new or existing analytic workspace using the `IMPORT_XML` procedure. In this way, you can create a copy of the analytic workspace in another schema or database.

This procedure can also be used as part of the process for upgrading OLAP standard form metadata contained in an Oracle OLAP 10g analytic workspace to OLAP 12c format.

### Syntax

```
DBMS_CUBE.EXPORT_XML_TO_FILE
(object_ids      IN      VARCHAR2,
 output_dirname  IN      VARCHAR2,
 output_filename IN      VARCHAR2;
```

```
DBMS_CUBE.EXPORT_XML_TO_FILE
(object_ids      IN      VARCHAR2,
 options_dirname IN      VARCHAR2,
 options_filename IN      VARCHAR2,
 output_dirname  IN      VARCHAR2,
 output_filename IN      VARCHAR2;
```

### Parameters

**Table 45-11** EXPORT\_XML\_TO\_FILE Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object_ids       | <p>Any of these identifiers.</p> <ul style="list-style-type: none"><li>• The name of a schema, such as <code>GLOBAL</code>.</li><li>• The fully qualified name of an analytic workspace in the form <i>owner.aw_name.AW</i>, such as <code>GLOBAL.GLOBAL.AW</code>.</li><li>• Cube</li><li>• Dimension</li><li>• Named build process</li><li>• Measure folder</li></ul> <p>You can specify multiple objects by separating the names with commas.</p> <p><b>Note:</b> When exporting an individual object, be sure to export any objects required to reconstruct it. For example, when you export a cube, you must also export the dimensions of the cube.</p> |
| options_dirname  | The case-sensitive name of a database directory that contains <i>options_filename</i> . See <a href="#">"Export Options"</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| options_filename | The name of a file containing an XML document of export options. See <a href="#">"Export Options"</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| output_dirname   | The case-sensitive name of a database directory where <i>output_filename</i> is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| output_filename  | The name of the template file created by the procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Export Options

The default settings for the export options are appropriate in most cases, and you can omit the *options\_dirname* and *options\_filename* parameters. However, when upgrading Oracle OLAP

10g metadata to OLAP 12c, you must specify an XML document that changes the default settings, like the following:

```
<?xml version="2.0"?>
<Export>
  <ExportOptions>
    <Option Name="SuppressNamespace" Value="True"/>
    <Option Name="SuppressOwner" Value="True"/>
    <Option Name="PreserveTableOwners" Value="True"/>
  </ExportOptions>
</Export>
```

You can create this XML document manually or by using the [CREATE\\_EXPORT\\_OPTIONS Procedure](#).

### Usage Notes

See "[DBMS\\_CUBE - Upgrading 10g Analytic Workspaces](#)".

### Examples

The following example generates an XML file named global.xml in OLAP 12c format using the default export settings. The metadata is derived from all analytic workspaces and CWM metadata in the GLOBAL\_AW schema. The output file is generated in the WORK\_DIR database directory.

```
execute dbms_cube.export_xml_to_file('GLOBAL_AW', 'WORK_DIR', 'global.xml');
```

The next example also generates an XML file named global.xml in OLAP 12c format using the export options set in options.xml. The metadata is derived from the GLOBAL analytic workspace in the GLOBAL\_AW schema. Both the options file and the output file are in the WORK\_DIR database directory.

```
execute dbms_cube.export_xml_to_file('GLOBAL_AW.GLOBAL.AW', 'WORK_DIR', 'options.xml',
'WORK_DIR', 'global.xml');
```

## 45.4.9 IMPORT\_XML Procedure

This procedure creates, modifies, or drops an analytic workspace by using an XML template.

### Syntax

```
DBMS_CUBE.IMPORT_XML
  (dirname          IN      VARCHAR2,
   filename         IN      VARCHAR2 );
```

```
DBMS_CUBE.IMPORT_XML
  (dirname          IN      VARCHAR2,
   filename         IN      VARCHAR2,
   out_xml          IN/OUT  CLOB );
```

```
DBMS_CUBE.IMPORT_XML
  (input_dirname    IN      VARCHAR2,
   input_filename   IN      VARCHAR2,
   options_dirname  IN      VARCHAR2,
   options_filename IN      VARCHAR2,
   out_xml          IN/OUT  CLOB );
```

```
DBMS_CUBE.IMPORT_XML
  (in_xml           IN      CLOB );
```

```

DBMS_CUBE.IMPORT_XML
  (in_xml          IN      CLOB,
   out_xml         IN/OUT CLOB );

DBMS_CUBE.IMPORT_XML
  (in_xml          IN      CLOB,
   options_xml     IN      CLOB,
   out_xml         IN/OUT CLOB );

```

## Parameters

**Table 45-12** IMPORT\_XML Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dirname          | The case-sensitive name of a database directory containing the XML document describing an analytic workspace.                                                                                                                                      |
| filename         | A file containing an XML document describing an analytic workspace.                                                                                                                                                                                |
| in_xml           | A CLOB containing an XML document describing an analytic workspace.                                                                                                                                                                                |
| input_dirname    | The case-sensitive name of a database directory containing the XML document describing an analytic workspace.                                                                                                                                      |
| input_filename   | A file containing an XML document describing an analytic workspace.                                                                                                                                                                                |
| options_dirname  | The case-sensitive name of a database directory containing a file of import options.                                                                                                                                                               |
| options_filename | A file of import options.                                                                                                                                                                                                                          |
| options_xml      | An XML document describing the import options. Use the <a href="#">CREATE_IMPORT_OPTIONS Procedure</a> to generate this document.                                                                                                                  |
| out_xml          | An XML document that either describes the analytic workspace or, for validation only, describes any errors. It may contain changes that DBMS_CUBE made to the imported XML, such as setting default values or making minor corrections to the XML. |

## Usage Notes

The XML can define, modify, or drop an entire analytic workspace, or one or more cubes or dimensions. When defining just cubes or dimensions, you must do so within an existing analytic workspace.

You can also use `IMPORT_XML` to drop an analytic workspace by using the XML document generated by the `DROP_MVIEW` procedure with the `EXPORTXML` parameter.

See "[DBMS\\_CUBE - Upgrading 10g Analytic Workspaces](#)".

## Example

This example loads an XML template from a file named `GLOBAL.XML` and located in a database directory named `XML_DIR`.

```
EXECUTE dbms_cube.import_xml('XML_DIR', 'GLOBAL.XML');
```

The next example exports an OLAP 10g template and uses `IMPORT_XML` to validate it before an upgrade to 12c.

```
DECLARE
```

```

exportOptClob clob;
importOptClob clob;
importClob    clob;
exportClob    clob;

BEGIN

  -- Create a CLOB for the export options
  dbms_lob.createtemporary(exportOptClob, TRUE);
  dbms_cube.create_export_options(out_options_xml=>exportOptClob,
suppress_namespace=>TRUE, preserve_table_owners=>TRUE);

  -- Create a CLOB for the XML template
  dbms_lob.createtemporary(exportClob, TRUE);

  -- Create a CLOB for import options
  dbms_lob.createtemporary(importOptClob, TRUE);
  dbms_cube.create_import_options(out_options_xml=>importOptClob, validate_only=>TRUE);

  -- Create a CLOB for the change log
  dbms_lob.createtemporary(importClob, TRUE);

  -- Enable Oracle Database 12c Release 1 (12.1) clients to access 10g metadata
  dbms_cube.initialize_cube_upgrade;

  -- Export metadata from an analytic workspace to a CLOB
  dbms_cube.export_xml(object_ids=>'GLOBAL_AW', options_xml=>exportOptClob,
out_xml=>exportClob);

  /* Import metadata from the CLOB. No objects are committed to the database
     because the validate_only parameter of CREATE_IMPORT_OPTIONS is set to
     TRUE.
  */

  dbms_cube.import_xml(in_xml=>exportClob, options_xml=>importOptClob,
out_xml=>importClob);

  -- Output the metadata changes
  dbms_output.put_line('This is the validation log:');
  dbms_output.put_line(importClob);

END;
/

```

The contents of `importClob` show that the XML is valid. Otherwise, error messages appear in the `<RootCommitResult>` element.

```

This is the validation log:
<?xml version="1.0" encoding="UTF-16"?>
<RootCommitResult>

</RootCommitResult>

```

For an example of `IMPORT_XML` within the context of an upgrade from 10g to 12c metadata, see the Custom Upgrade section of ["DBMS\\_CUBE - Upgrading 10g Analytic Workspaces"](#).

## 45.4.10 INITIALIZE\_CUBE\_UPGRADE Procedure

This procedure processes analytic workspaces created in Oracle OLAP 10g so they can be used by Oracle OLAP 12c clients. It processes all analytic workspaces in the current schema. Run this procedure once for each schema in which there are 10g analytic workspaces.

Without this processing step, 12c clients cannot connect to a database containing a 10g analytic workspace with subobjects of a dimension or cube having the same name. Additionally, some DBMS\_CUBE procedures and functions, such as EXPORT\_XML and EXPORT\_XML\_TO\_FILE, do not work on the 10g metadata.

After processing, OLAP 12c clients can connect and use the alternate names provided by INITIALIZE\_CUBE\_UPGRADE for the conflicting subobjects. OLAP 10g clients continue to use the original names.

INITIALIZE\_CUBE\_UPGRADE does not upgrade any OLAP 10g objects to OLAP 12c format.

See ["DBMS\\_CUBE - Upgrading 10g Analytic Workspaces"](#).

### Syntax

```
DBMS_CUBE.INITIALIZE_CUBE_UPGRADE;
```

### Usage Notes

This procedure creates and populates a table named CUBE\_UPGRADE\_INFO. If it already exists, the table is truncated and repopulated.

While the 10g namespace allowed subobjects with the same name in the same dimension or cube, the 12c namespace does not. When INITIALIZE\_CUBE\_UPGRADE detects a name conflict among subobjects such as levels, hierarchies, and dimension attributes, it creates a row in CUBE\_UPGRADE\_INFO providing a new, unique name for each one. Rows may also be created for objects that do not require renaming; these rows are distinguished by a value of 0 or null in the CONFLICT column. Top-level objects, such as dimensions and cubes, are not listed.

You can edit the table using SQL INSERT and UPDATE if you want to customize the names of OLAP 10g objects on OLAP 12c clients.

The UPGRADE\_AW, EXPORT\_XML and EXPORT\_XML\_TO\_FILE procedures use the names specified in the NEW\_NAME column of the table to identify objects in CWM or OLAP standard form (AWXML) analytic workspaces, rather than the original names.

The following table describes the columns of CUBE\_UPGRADE\_INFO.

| Column       | Datatype | NULL     | Description                                                                                                                                                                                 |
|--------------|----------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER        | VARCHAR2 | NOT NULL | Owner of the analytic workspace.                                                                                                                                                            |
| AW           | VARCHAR2 | NOT NULL | Name of the analytic workspace.                                                                                                                                                             |
| AWXML_ID     | VARCHAR2 | NOT NULL | Full logical name of the object requiring modification, in the form <i>simple_name.[subtype_name].object_type</i> . For example, <i>TIME.DIMENSION</i> and <i>PRODUCT.COLOR.ATTRIBUTE</i> . |
| NEW_NAME     | VARCHAR2 | NOT NULL | The name the object will have in Oracle 12c after the upgrade.                                                                                                                              |
| OBJECT_CLASS | VARCHAR2 | --       | DerivedMeasure for calculated measures, or empty for all other object types.                                                                                                                |

| Column   | Datatype | NULL | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------|----------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONFLICT | NUMBER   | --   | Indicates the reason that the row was added to CUBE_UPGRADE_INFO: <ul style="list-style-type: none"> <li>0: The object does not have a naming conflict but appears in the table for other reasons.</li> <li>1: Two objects have the same name and would create a conflict in the OLAP 12c namespace. The object type (such as level or hierarchy) will be added to the names.</li> </ul> |

### Examples

The following command creates and populates the CUBE\_UPGRADE\_INFO table:

```
EXECUTE dbms_cube.initialize_cube_upgrade;
```

The table shows that the OLAP 10g analytic workspace has a hierarchy and a level named MARKET\_SEGMENT, which will be renamed. The table also contains rows for calculated measures, but these objects do not require renaming: The value of CONFLICT is 0.

```
SELECT awxml_id, new_name, conflict FROM cube_upgrade_info;
```

| AWXML_ID                               | NEW_NAME                 | CONFLICT |
|----------------------------------------|--------------------------|----------|
| CUSTOMER.MARKET_SEGMENT.HIERARCHY      | MARKET_SEGMENT_HIERARCHY | 1        |
| CUSTOMER.MARKET_SEGMENT.LEVEL          | MARKET_SEGMENT_LEVEL     | 1        |
| UNITS_CUBE.EXTENDED_COST.MEASURE       | EXTENDED_COST            | 0        |
| UNITS_CUBE.EXTENDED_MARGIN.MEASURE     | EXTENDED_MARGIN          | 0        |
| UNITS_CUBE.CHG_SALES_PP.MEASURE        | CHG_SALES_PP             | 0        |
| UNITS_CUBE.CHG_SALES_PY.MEASURE        | CHG_SALES_PY             | 0        |
| UNITS_CUBE.PCTCHG_SALES_PP.MEASURE     | PCTCHG_SALES_PP          | 0        |
| UNITS_CUBE.PCTCHG_SALES_PY.MEASURE     | PCTCHG_SALES_PY          | 0        |
| UNITS_CUBE.PRODUCT_SHARE.MEASURE       | PRODUCT_SHARE            | 0        |
| UNITS_CUBE.CHANNEL_SHARE.MEASURE       | CHANNEL_SHARE            | 0        |
| UNITS_CUBE.MARKET_SHARE.MEASURE        | MARKET_SHARE             | 0        |
| UNITS_CUBE.CHG_EXTMRGN_PP.MEASURE      | CHG_EXTMRGN_PP           | 0        |
| UNITS_CUBE.CHG_EXTMRGN_PY.MEASURE      | CHG_EXTMRGN_PY           | 0        |
| UNITS_CUBE.PCTCHG_EXTMRGN_PP.MEASURE   | PCTCHG_EXTMRGN_PP        | 0        |
| UNITS_CUBE.PCTCHG_EXTMRGN_PY.MEASURE   | PCTCHG_EXTMRGN_PY        | 0        |
| UNITS_CUBE.CHG_UNITS_PP.MEASURE        | CHG_UNITS_PP             | 0        |
| UNITS_CUBE.EXTMRGN_PER_UNIT.MEASURE    | EXTMRGN_PER_UNIT         | 0        |
| UNITS_CUBE.SALES_YTD.MEASURE           | SALES_YTD                | 0        |
| UNITS_CUBE.SALES_YTD_PY.MEASURE        | SALES_YTD_PY             | 0        |
| UNITS_CUBE.PCTCHG_SALES_YTD_PY.MEASURE | PCTCHG_SALES_YTD_PY      | 0        |
| UNITS_CUBE.SALES_QTD.MEASURE           | SALES_QTD                | 0        |
| UNITS_CUBE.CHG_UNITS_PY.MEASURE        | CHG_UNITS_PY             | 0        |

## 45.4.11 REFRESH\_MVIEW Procedure

This procedure refreshes the data in a cube materialized view.

### Syntax

```
DBMS_CUBE.REFRESH_MVIEW (
    mvowner          IN  VARCHAR2,
    mvname           IN  VARCHAR2,
    method           IN  VARCHAR2          DEFAULT NULL,
    refresh_after_errors IN  BOOLEAN        DEFAULT FALSE,
    parallelism      IN  BINARY_INTEGER   DEFAULT 0,
```

```

atomic_refresh    IN  BOOLEAN    DEFAULT FALSE,
scheduler_job     IN  VARCHAR2   DEFAULT NULL,
sam_parameters    IN  CLOB       DEFAULT NULL,
nested           IN  BOOLEAN    DEFAULT FALSE );

```

## Parameters

**Table 45-13 REFRESH\_MVIEW Procedure Parameters**

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mvowner              | Owner of the cube materialized view.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| mvname               | Name of the cube materialized view.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| method               | <p>A full or a fast (partial) refresh. In a fast refresh, only changed rows are inserted in the cube and the affected areas of the cube are re-aggregated.</p> <p>You can specify a method for each cube in sequential order, or a single method to apply to all cubes. If you list more cubes than methods, then the last method applies to the additional cubes.</p> <ul style="list-style-type: none"> <li>• C: Complete refresh clears all dimension values before loading. (Default)</li> <li>• F: Fast refresh of a cube materialized view, which performs an incremental refresh and re-aggregation of only changed rows in the source table.</li> <li>• ?: Fast refresh if possible, and otherwise a complete refresh.</li> <li>• P: Recomputes rows in a cube materialized view that are affected by changed partitions in the detail tables.</li> <li>• S: Fast solve of a compressed cube. A fast solve reloads all the detail data and re-aggregates only the changed values.</li> </ul> <p>See the "<a href="#">Usage Notes</a>" for the <code>BUILD</code> procedure for additional details.</p> |
| refresh_after_errors | <p><code>TRUE</code> to roll back just the cube or dimension with errors, and then continue building the other objects.</p> <p><code>FALSE</code> to roll back all objects in the build.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| nested               | <p><code>TRUE</code> performs nested refresh operations for the specified set of cube materialized views. Nested refresh operations refresh all the depending materialized views and the specified set of materialized views based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables.</p> <p>All objects must reside in a single analytic workspace.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Usage Notes

REFRESH\_MVIEW changes *mvname* to the name of the cube, then passes the cube name and all parameters to the BUILD procedure. Thus, you can use the BUILD procedure to refresh a cube materialized view. See the ["BUILD Procedure"](#) for additional information about the parameters.

## Examples

The following example uses the default settings to refresh a cube materialized view named CB\$FWEEK\_PSCAT\_SALES.

```
SET serverout ON format wrapped
```

```
EXECUTE dbms_cube.refresh_mview('SH', 'CB$FWEEK_PSCAT_SALES');
```

The next example changes the refresh method to use fast refresh if possible, continue refreshing after an error, and use two parallel processes.

```
EXECUTE dbms_cube.refresh_mview('SH', 'CB$FWEEK_PSCAT_SALES', '?', TRUE, 2);
```

After successfully refreshing the cube materialized view, REFRESH\_MVIEW returns a message like the following:

```
Completed refresh of cube mview "SH"."CB$FWEEK_PSCAT_SALES" at 20130212 15:04:46.370.
```

## 45.4.12 UPGRADE\_AW Procedure

This procedure creates an Oracle OLAP 12c analytic workspace from a copy of the metadata contained in an OLAP 10g analytic workspace. The original OLAP 10g analytic workspace is not affected and can exist at the same time and in the same schema as the OLAP 12c analytic workspace.

UPGRADE\_AW automatically runs INITIALIZE\_CUBE\_UPGRADE if the CUBE\_UPGRADE\_INFO table does not exist. If it does exist, then UPGRADE\_AW does not overwrite it, thus preserving any changes you made to the table.

See ["DBMS\\_CUBE - Upgrading 10g Analytic Workspaces"](#).

## Syntax

```
DBMS_CUBE.UPGRADE_AW  
  (sourceaw          IN  VARCHAR2,  
   destaw            IN  VARCHAR2,  
   upgoptions        IN  CLOB DEFAULT NULL);
```

## Parameters

**Table 45-14 UPGRADE\_AW Procedure Parameters**

| Parameter | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| sourceaw  | The name of a 10g analytic workspace.                                                           |
| destaw    | A new name for the generated 12c analytic workspace. It cannot be the same as <i>sourceaw</i> . |

**Table 45-14 (Cont.) UPGRADE\_AW Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| upgoptions | <p>One or more of these upgrade options, as a string in the form 'OPTION=VALUE'. Separate multiple options with commas.</p> <ul style="list-style-type: none"> <li><b>PRESERVE_TABLE_OWNERS:</b><br/>YES preserves the original source table mappings. Use this option when creating an OLAP 12c analytic workspace in a different schema from the 10g analytic workspace, and you want the new objects mapped to tables in the original schema. (Default)<br/>NO removes the schema owner from the source table mappings. Use this option when creating an OLAP 12c analytic workspace in a different schema from the 10g analytic workspace, and you want the new objects mapped to tables in the destination schema.</li> <li><b>RENAME_TABLE:</b> The name of a table that specifies new names for objects as they are created in OLAP 12c format. These changes are in addition to those specified by the INITIALIZE_CUBE_UPGRADE procedure. See <a href="#">"CREATE_IMPORT_OPTIONS Procedure"</a> for information about creating a rename table.</li> <li><b>TARGET_VERSION:</b> The version of the upgrade, specified by a 2- to 5-part number, such as 11.2 or 11.2.0.2.0. If you enter an unsupported version number, then the closest version below it is used.</li> </ul> |

### Examples

This example upgrades an OLAP 10g analytic workspace named GLOBAL10 to an OLAP 12c analytic workspace named GLOBAL12, using a rename table named MY\_OBJECT\_MAP:

```
BEGIN

    -- Upgrade the analytic workspace
    dbms_cube.upgrade_aw(sourceaw =>'GLOBAL10', destaw => 'GLOBAL12', upgoptions =>
'RENAME_TABLE=MY_OBJECT_MAP');

    -- Load and aggregate the data
    dbms_cube.build(script=>'UNITS_CUBE, PRICE_AND_COST_CUBE');

END;
/
```

## 45.4.13 VALIDATE\_XML Procedure

This procedure checks the XML to assure that it is valid without committing the results to the database. It does not create an analytic workspace.

### Syntax

```
DBMS_CUBE.VALIDATE_XML
    (dirname          IN  VARCHAR2,
     filename         IN  VARCHAR2 );

DBMS_CUBE.VALIDATE_XML
    (in_xml          IN  CLOB );
```

## Parameters

**Table 45-15** VALIDATE\_XML Procedure Parameters

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| dirname   | The case-sensitive name of a database directory. |
| filename  | The name of a file containing an XML template.   |
| IN_XML    | The name of a CLOB containing an XML template.   |

## Usage Notes

You should always load a template into the same version and release of Oracle Database as the one used to generate the template. The XML may not be valid if it was generated by a different release of the software.

## Example

This example reports a problem in the schema:

```
EXECUTE dbms_cube.validate_xml('UPGRADE_DIR', 'MYGLOBAL.XML');
BEGIN dbms_cube.validate_xml('UPGRADE_DIR', 'MYGLOBAL.XML'); END;

*
ERROR at line 1:
ORA-37162: OLAP error
'GLOBAL.PRICE_CUBE.$AW_ORGANIZATION': XOQ-01950: The AWCubeOrganization for
cube "GLOBAL.PRICE_CUBE" contains multiple BuildSpecifications with the same
name.
'GLOBAL.UNITS_CUBE.$AW_ORGANIZATION': XOQ-01950: The AWCubeOrganization for
cube "GLOBAL.UNITS_CUBE" contains multiple BuildSpecifications with the same
name.
XOQ-01400: invalid metadata objects
ORA-06512: at "SYS.DBMS_CUBE", line 411
ORA-06512: at "SYS.DBMS_CUBE", line 441
ORA-06512: at "SYS.DBMS_CUBE", line 501
ORA-06512: at "SYS.DBMS_CUBE", line 520
ORA-06512: at line 1
```

After the problems are corrected, the procedure reports no errors:

```
EXECUTE dbms_cube.validate_xml('UPGRADE_DIR', 'MYGLOBAL.XML');

PL/SQL procedure successfully completed.
```

This example loads an XML template into a temporary CLOB, then validates it. The script is named GLOBAL.XML, and it is located in a database directory named XML\_DIR.

```
DEFINE xml_file = 'GLOBAL.XML';

SET ECHO ON;
SET SERVEROUT ON;

DECLARE
    xml_file      BFILE := bfilename('XML_DIR', '&xml_file');
    in_xml        CLOB;
    out_xml       CLOB := NULL;
    dest_offset    INTEGER := 1;
```

```
src_offset    INTEGER := 1;
lang_context  INTEGER := 0;
warning       INTEGER;
BEGIN
    -- Setup the clob from a file
    DBMS_LOB.CREATETEMPORARY(in_xml, TRUE);
    DBMS_LOB.OPEN(in_xml, DBMS_LOB.LOB_READWRITE);
    DBMS_LOB.OPEN(xml_file, DBMS_LOB.FILE_READONLY);
    DBMS_LOB.LOADCLOBFROMFILE(in_xml, xml_file, DBMS_LOB.LOBMAXSIZE,
        dest_offset, src_offset, 0, lang_context, warning);

    -- Validate the xml
    DBMS_CUBE.VALIDATE_XML(in_xml);
END;
/
```

# DBMS\_CUBE\_ADVICE

DBMS\_CUBE\_ADVICE contains subprograms for evaluating cube materialized views to support log-based fast refresh and query rewrite.

This chapter contains the following topics:

- [DBMS\\_CUBE\\_ADVICE Security Model](#)
- [Summary of DBMS\\_CUBE\\_ADVICE Subprograms](#)

## See Also:

*Oracle OLAP User's Guide* for information about cube materialized views

## 46.1 DBMS\_CUBE\_ADVICE Security Model

The MV\_CUBE\_ADVICE function requires the ADVISOR privilege.

## 46.2 Summary of DBMS\_CUBE\_ADVICE Subprograms

This table lists and describes the DBMS\_CUBE\_ADVICE subprograms.

**Table 46-1 Summary of DBMS\_CUBE\_ADVICE Subprograms**

| Subprogram                                      | Description                                                                                                                                                                                                                   |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MV_CUBE_ADVICE Function</a>         | Evaluates the metadata of a cube materialized view and generates recommendations for constraints, SQL dimension objects, and materialized view logs to support a broad range of query rewrite and fast refresh opportunities. |
| <a href="#">SET_CNS_EXCEPTION_LOG Procedure</a> | Identifies the name of an exception log used in validated constraints generated by MV_CUBE_ADVICE.                                                                                                                            |
| <a href="#">TRACE Procedure</a>                 | Displays or suppresses diagnostic messages for MV_CUBE_ADVICE.                                                                                                                                                                |

### 46.2.1 MV\_CUBE\_ADVICE Function

This table function evaluates the metadata for a specified cube materialized view. It generates recommendations and returns them as a SQL result set. These SQL statements can be used to create constraints, SQL dimension objects, and materialized view logs that allow the broadest range of query rewrite transformations and log-based fast refresh of the cube materialized view.

#### Syntax

```
DBMS_CUBE_ADVICE.MV_CUBE_ADVICE (
    owner          IN VARCHAR2 DEFAULT USER,
```

```

        mvname      IN  VARCHAR2,
        reqtype     IN  VARCHAR2  DEFAULT '0',
        validate    IN  NUMBER    DEFAULT 0)
RETURN COAD_ADVICE_T PIPELINED;
```

## Parameters

**Table 46-2 MV\_CUBE\_ADVISE Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| owner     | Owner of the cube materialized view                                                                                                                                                                                                                                                                                            |
| mvname    | Name of the cube, such as UNITS_CUBE, or the cube materialized view, such as CB\$UNITS_CUBE                                                                                                                                                                                                                                    |
| reqtype   | Type of advice to generate: <ul style="list-style-type: none"> <li>0: All applicable advice types</li> <li>1: Column NOT NULL constraints</li> <li>2: Primary key constraints</li> <li>3: Foreign key constraints</li> <li>4: Relational dimension objects</li> <li>5: Cube materialized view logs with primary key</li> </ul> |
| validate  | Validation option: <ul style="list-style-type: none"> <li>0: Validate the constraints</li> <li>1: Do not validate the constraints</li> </ul>                                                                                                                                                                                   |

## Returns

A table of type COAD\_ADVICE\_T, consisting of a set of rows of type COAD\_ADVICE\_REC. [Table 46-3](#) describes the columns.

**Table 46-3 MV\_CUBE\_ADVISE Return Values**

| Column     | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER      | VARCHAR2 (30)  | Owner of the dimensional object identified in APIOBJECT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| APIOBJECT  | VARCHAR2 (30)  | Name of a cube enhanced with materialized view capabilities, such as UNITS_CUBE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SQLOBJOWN  | VARCHAR2 (30)  | Owner of the relational object identified in SQLOBJECT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| SQLOBJECT  | VARCHAR2 (65)  | Name of the master table, such as UNITS_FACT, or the cube materialized view, such as CB\$UNITS_CUBE.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ADVICETYPE | NUMBER (38, 0) | Type of recommendation: <ul style="list-style-type: none"> <li>1: Create NOT NULL constraints on the foreign key columns</li> <li>2: Create primary key constraints on the master table</li> <li>3: Create primary key constraints on the master view</li> <li>4: Create foreign key constraints on the master table</li> <li>5: Create foreign key constraints on the master view</li> <li>6: Create relational dimensions on the master dimension tables</li> <li>7: Create a materialized view log</li> <li>8: Compile the materialized view</li> </ul> |

**Table 46-3 (Cont.) MV\_CUBE\_ADVISE Return Values**

| Column      | Datatype | Description                                                                                                                                                 |
|-------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DISPOSITION | CLOB     | Pre-existing conditions that conflict with the recommendations and should be resolved before <code>SQLTEXT</code> can be executed.                          |
| SQLTEXT     | CLOB     | SQL statement that implements the recommendation.                                                                                                           |
| DROPTTEXT   | CLOB     | SQL statement that reverses <code>SQLTEXT</code> .<br>Pre-existing conditions may prevent these statements from restoring the schema to its previous state. |

### Usage Notes

This function is available in Analytic Workspace Manager as the Materialized View Advisor, which will generate a SQL script with the recommendations.

You can query the returned rows the same as any other table, as shown in the example.

`MV_CUBE_ADVISE` generates unique object names each time it is called. You should execute the function once, capture the results, and work with those SQL statements.

Take care when dropping database objects. If a table already has a materialized view log, it will have the same name used in the `SQL DROP MATERIALIZED VIEW LOG` statement in the `DROPTTEXT` column. You should avoid inadvertently dropping materialized view logs, especially when they may be used for remote data replication.

### Examples

The following query displays the SQL statements recommended by `MV_CUBE_ADVISE`. `UNITS_FACT` is the master table for `UNITS_CUBE`, and `MV_CUBE_ADVISE` generates an `ALTER TABLE` command to add primary key constraints.

It also generates an `ALTER MATERIALIZED VIEW` command to compile the `CB$UNITS_CUBE` cube materialized view.

```
SQL> SELECT apiobject, sqlobject, sqltext
       FROM TABLE(dbms_cube_advise.mv_cube_advise('GLOBAL', 'CB$UNITS_CUBE'));
```

| APIOBJECT  | SQLOBJECT      | SQLTEXT                                                                                                                                                  |
|------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| UNITS_CUBE | UNITS_FACT     | alter table "GLOBAL"."UNITS_FACT" add constraint "COAD_PK000208" PRIMARY KEY ("CHANNEL_ID", "ITEM_ID", "SHIP_TO_ID", "MONTH_ID") rely disable novalidate |
| UNITS_CUBE | CB\$UNITS_CUBE | alter materialized view "GLOBAL"."CB\$UNITS_CUBE" compile                                                                                                |

## 46.2.2 SET\_CNS\_EXCEPTION\_LOG Procedure

This procedure identifies the name of an exception log used in validated constraints generated by MV\_CUBE\_ADVICE.

### Syntax

```
DBMS_CUBE_ADVICE.SET_CNS_EXCEPTION_LOG (
    exceptlogtab IN VARCHAR2 DEFAULT user.EXCEPTIONS);
```

### Parameters

**Table 46-4 SET\_CNS\_EXCEPTION\_LOG Procedure Parameters**

| Parameter    | Description                            |
|--------------|----------------------------------------|
| exceptlogtab | The name of an existing exception log. |

### Usage Notes

To create an exception log, use the `utlexcpt.sql` or the `utlexpt1.sql` script before executing `SET_CNS_EXCEPTION_LOG`.

The `validate` parameter of `MV_CUBE_ADVICE` must be set to 1.

### Examples

The `utlexcpt.sql` script creates a table named `EXCEPTIONS`, and the `SET_CNS_EXCEPTION_LOG` procedure identifies it as the exception log for `MV_CUBE_ADVICE`. The `ALTER TABLE` statement now includes the clause `VALIDATE EXCEPTIONS INTO "GLOBAL"."EXCEPTIONS"`.

```
SQL> @utlexcpt
Table created.
```

```
SQL> EXECUTE dbms_cube_advice.set_cns_exception_log;
PL/SQL procedure successfully completed.
```

```
SQL> SELECT apiobject, sqlobject, advicetype type, sqltext
       FROM TABLE(
         dbms_cube_advice.mv_cube_advice('GLOBAL', 'CB$UNITS_CUBE', '2', 1));
```

| APIOBJECT  | SQLOBJECT      | TYPE | SQLTEXT                                                                                                                                                                                       |
|------------|----------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UNITS_CUBE | UNITS_FACT     | 2    | alter table "GLOBAL"."UNITS_FACT" add constraint "COAD_PK000219" PRIMARY KEY ("CHANNEL_ID", "ITEM_ID", "SHIP_TO_ID", "MONTH_ID") norely enable validate exceptions into "GLOBAL"."EXCEPTIONS" |
| UNITS_CUBE | CB\$UNITS_CUBE | 8    | alter materialized view "GLOBAL"."CB\$UNITS_CUBE" compile                                                                                                                                     |

## 46.2.3 TRACE Procedure

This procedure turns on and off diagnostic messages to server output for the `MV_CUBE_ADVISE` function.

### Syntax

```
DBMS_CUBE_ADVISE.TRACE (
    diaglevel          IN  BINARY_INTEGER DEFAULT 0);
```

### Parameters

**Table 46-5 TRACE Procedure Parameters**

| Parameter | Description                                     |
|-----------|-------------------------------------------------|
| diaglevel | 0 to turn tracing off, or 1 to turn tracing on. |

### Examples

The following example directs the diagnostic messages to server output. The SQL\*Plus `SERVEROUTPUT` setting displays the messages.

```
SQL> SET SERVEROUT ON FORMAT WRAPPED
SQL> EXECUTE dbms_cube_advise.trace(1);
DBMS_COAD_DIAG: Changing diagLevel from [0] to [1]
```

PL/SQL procedure successfully completed.

```
SQL> SELECT sqlobject, sqltext, droptext
FROM TABLE(
    dbms_cube_advise.mv_cube_advise('GLOBAL', 'CB$UNITS_CUBE'))
WHERE apiobject='UNITS_CUBE';
```

| SQLOBJECT      | SQLTEXT                                                                                                                                                              | DROPTEXT                                                                     |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| UNITS_FACT     | alter table "GLOBAL"."UNITS_FACT" add co<br>nstraint "COAD_PK000222" PRIMARY KEY ("C<br>HANNEL_ID", "ITEM_ID", "SHIP_TO_ID", "MO<br>NTH_ID") rely disable novalidate | alter table "GLOBAL"."UNITS_FACT" drop c<br>nstraint "COAD_PK000222" cascade |
| CB\$UNITS_CUBE | alter materialized view "GLOBAL"."CB\$UNI<br>TS_CUBE" compile                                                                                                        | alter materialized view "GLOBAL"."CB\$UNI<br>TS_CUBE" compile                |

```

# DBMS\_CUBE\_LOG

DBMS\_CUBE\_LOG contains subprograms for creating and managing logs for cubes and cube dimensions.

## See Also:

OLAP Technology in the Oracle Database in *Oracle OLAP User's Guide* regarding use of the OLAP option to support business intelligence and analytical applications.

This chapter contains the following topics:

- [Using DBMS\\_CUBE\\_LOG](#)
- [Summary of DBMS\\_CUBE\\_LOG Subprograms](#)

## 47.1 Using DBMS\_CUBE\_LOG

DBMS\_CUBE\_LOG manages several logs that enable you to track the progress of long running processes, then use the results to profile performance characteristics.

They provide information to help you diagnose and remedy problems that may occur during development and maintenance of a cube, such as hierarchies that are improperly structured in the relational source tables, records that fail to load, or data refreshes that take too long to complete. They also help diagnose performance problems in querying cubes.

Analytic Workspace Manager creates the logs automatically using the default names and types. It also disables the logs when Analytic Workspace Manager is closed. To use the same logs outside of Analytic Workspace Manager, you must first enable them. Alternatively, you can create and manage different logs for use outside of Analytic Workspace Manager.

This section contains the following topics:

- [Logging Types](#)
- [Logging Targets](#)
- [Verbosity Levels](#)
- [Security Model](#)
- [Creating Cube Logs](#)
- [Cube Build Log](#)
- [Cube Dimension Compile Log](#)
- [Cube Operations Log](#)
- [Cube Rejected Records Log](#)

## 47.1.1 DBMS\_CUBE\_LOG — Logging Types

Several logs are available, each one dedicated to storing messages of a particular type. You may use all of them or only those that you find particularly valuable.

The logs and their contents are described later in this topic.

- [Cube Build Log](#)
- [Cube Dimension Compile Log](#)
- [Cube Operations Log](#)
- [Cube Rejected Records Log](#)

DBMS\_CUBE\_LOG provides functions that return the binary integer for each log type. You can produce more readable code by using these functions instead of integers for the argument values of other DBMS\_CUBE\_LOG procedures and functions. Refer to these descriptions:

- [TYPE\\_BUILD Function](#)
- [TYPE\\_DIMENSION\\_COMPILE Function](#)
- [TYPE\\_OPERATIONS Function](#)
- [TYPE\\_REJECTED\\_RECORDS Function](#)

## 47.1.2 DBMS\_CUBE\_LOG — Logging Targets

The TABLE\_CREATE procedure creates database tables for storing the logs. Using the ENABLE procedure, you can create additional targets with changes in the destination or logging level. For example, you might target the Cube Operations log to both a table and a disk file.

These are the available targets:

- Disk file
- LOB
- Database table
- Trace file

See [ENABLE Procedure](#) for more information about creating multiple targets.

DBMS\_CUBE\_LOG provides functions that return the binary integer for each target type. You can produce more readable code by using these functions instead of integers for the argument values of other DBMS\_CUBE\_LOG procedures and functions. Refer to these descriptions:

- [TARGET\\_FILE Function](#)
- [TARGET\\_LOB Function](#)
- [TARGET\\_TABLE Function](#)
- [TARGET\\_TRACE Function](#)

### 47.1.3 DBMS\_CUBE\_LOG — Verbosity Levels

You can decide how much information is recorded in a log. You may want fewer details when leaving a job to run overnight than when you are monitoring the success of a new build. You can choose from these verbosity levels. Each level adds to the preceding level.

- **LOWEST:** Logs the status of each command used to build the cube dimensions and cubes, the use of slave processes, and summary records. This is the basic logging level.
- **LOW:** Logs messages from the OLAP engine, such as start and finish records for SQL Import, Aggregate, and Update.
- **MEDIUM:** Logs messages at the level used by Analytic Workspace Manager.
- **HIGH:** Logs messages that provide tuning information, such as composite lengths, partitioning details, object sizes, and aggregation work lists. This level is intended for use by Oracle Field Services.
- **HIGHEST:** Logs debugging messages and other information typically sent to a trace file. This level is intended for use by Oracle Support Services.

DBMS\_CUBE\_LOG provides functions that return the binary integer for each verbosity level. You can produce more readable code by using these functions instead of integers for the argument values of other DBMS\_CUBE\_LOG procedures and functions. Refer to these descriptions:

- [LEVEL\\_LOWEST Function](#)
- [LEVEL\\_LOW Function](#)
- [LEVEL\\_MEDIUM Function](#)
- [LEVEL\\_HIGH Function](#)
- [LEVEL\\_HIGHEST Function](#)

### 47.1.4 DBMS\_CUBE\_LOG Security Model

The TABLE\_CREATE procedure requires the CREATE TABLE privilege.

### 47.1.5 DBMS\_CUBE\_LOG — Creating Cube Logs

To store logging information in a database table, you must create that table using the TABLE\_CREATE procedure. Cube Build logs are always stored in tables. The ENABLE procedure creates the other target types for the other logs.

**To create a Cube Build log:**

- Execute the TABLE\_CREATE procedure.

The following command creates a Cube Build log with the default name of CUBE\_BUILD\_LOG:

```
EXECUTE dbms_cube_log.table_create(dbms_cube_log.type_build);
```

**To create a Cube Dimension Compile log, Cube Operations log, or Cube Rejected Records log with a database table target:**

1. Execute the TABLE\_CREATE procedure to create the table.
2. Execute the ENABLE procedure to begin logging.

These commands create and enable a Cube Operations table with the default name of CUBE\_OPERATIONS\_LOG and the default verbosity level:

```
EXECUTE dbms_cube_log.table_create(dbms_cube_log.type_operations);
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations);
```

**To create a Cube Dimension Compile log, Cube Operations log, or Cube Rejected Records log with a trace file, disk file, or LOB target:**

- Execute the `ENABLE` procedure.

This command enables the Cube Rejected Records log, sets verbosity to the lowest level, and directs the output to a disk file named `rejects.log` in the `WORK_DIR` database directory:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_rejected_records, -
    dbms_cube_log.target_file, dbms_cube_log.level_lowest, -
    'WORK_DIR/rejects.log');
```

## 47.1.6 DBMS\_CUBE\_LOG — Cube Build Log

The Cube Build log provides information about what happened during a build. Use this log to determine whether the build produced the results you were expecting, and if not, why not.

The contents of the Cube Build log are refreshed continuously during a build. You can query the log at any time to evaluate the progress of the build and to estimate the time to completion.

The default name of the Cube Build log is `CUBE_BUILD_LOG`. The following table describes its contents.

### Note:

To manage a Cube Build log, use only the `TABLE_CREATE` and `VERSION` procedures.

| Column            | Datatype       | NULL | Description                                                                                                                                                          |
|-------------------|----------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BUILD_ID          | NUMBER         | --   | A unique sequence number for the build. The same number is used for slave processes in a parallel build.                                                             |
| SLAVE_NUMBER      | NUMBER         | --   | A counter for slave processes in a parallel build: 0 is the master process, 1 is the first slave, 2 is the second slave, and so forth.                               |
| STATUS            | VARCHAR2 (10)  | --   | The current status of the command: <code>STARTED</code> , <code>COMPLETED</code> , <code>FAILED</code> , or <code>WORKING</code> .                                   |
| COMMAND           | VARCHAR2 (25)  | --   | The name of the command being executed, such as <code>BUILD</code> , <code>LOAD</code> , and <code>SOLVE</code> .                                                    |
| BUILD_OBJECT      | VARCHAR2 (500) | --   | The name of the cube or cube dimension being processed.                                                                                                              |
| BUILD_OBJECT_TYPE | VARCHAR2 (10)  | --   | The type of object: <code>CUBE</code> , <code>DIMENSION</code> , or <code>BUILD</code> .                                                                             |
| OUTPUT            | CLOB           | --   | Information structured like an XML document about the command, or <code>NULL</code> when there is no additional information, such as for a <code>STARTED</code> row. |

| Column                | Datatype       | NULL | Description                                                                                                                                                                                                                                                                 |
|-----------------------|----------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AW                    | VARCHAR2 (30)  | --   | The name of the analytic workspace that contains the objects of the build.                                                                                                                                                                                                  |
| OWNER                 | VARCHAR2 (30)  | --   | The owner of the analytic workspace and all the objects of the build.                                                                                                                                                                                                       |
| PARTITION             | VARCHAR2 (10)  | --   | The name of the partition being processed, or <b>NULL</b> when the current operation does not correspond to a partition.                                                                                                                                                    |
| SCHEDULER_JOB         | VARCHAR2 (100) | --   | A user-specified string to identify the build.                                                                                                                                                                                                                              |
| TIME                  | TIMESTAMP (6)  | --   | The time the row is added to the table.                                                                                                                                                                                                                                     |
| BUILD_SCRIPT          | CLOB           | --   | The cube build script. Populated only in rows where <b>COMMAND</b> is <b>BUILD</b> .                                                                                                                                                                                        |
| BUILD_TYPE            | VARCHAR2 (22)  | --   | The origin of the build: <b>DBMS_CUBE</b> , <b>DBMS_MVIEW</b> , <b>JAVA</b> , or <b>SLAVE</b> .                                                                                                                                                                             |
| COMMAND_DEPTH         | NUMBER (2)     | --   | The nesting depth of the command. For example, <b>COMPILE HIERARCHIES</b> is a component step of <b>COMPILE</b> , so if <b>COMPILE</b> has a depth of 1, then <b>COMPILE HIERARCHIES</b> has a depth of 2.                                                                  |
| BUILD_SUB_OBJECT      | VARCHAR2 (30)  | --   | The name of a subobject being processed, such as a measure that does not inherit the aggregation rules of the cube.                                                                                                                                                         |
| REFRESH_METHOD        | VARCHAR2 (1)   | --   | The refresh method, such as <b>C</b> or <b>F</b> , that is associated with the current command. The refresh method is important only for the <b>CLEAR</b> step.                                                                                                             |
| SEQ_NUMBER            | NUMBER         | --   | Not currently used.                                                                                                                                                                                                                                                         |
| COMMAND_NUMBER        | NUMBER         | --   | The sequence number of the command in the current process, which can be used to distinguish the same command on different objects. For example, a <b>LOAD</b> on <b>PRODUCT</b> and a <b>LOAD</b> on <b>TIME</b> .                                                          |
| IN_BRANCH             | NUMBER (1)     | --   | Not currently used.                                                                                                                                                                                                                                                         |
| COMMAND_STATUS_NUMBER | NUMBER         | --   | Identifies the sequence number of all rows for a particular command. For example, a particular command might be represented by four rows: The first row has a status of <b>STARTED</b> and the last row has a status of <b>COMPLETED</b> . This column is used for sorting. |

## 47.1.7 DBMS\_CUBE\_LOG — Cube Dimension Compile Log

When solving a cube, OLAP checks the dimension hierarchies to make sure they are valid. Errors that occur during this validation are written to the Cube Dimension Compile log.

The checks include:

- **Circularity:** Hierarchies are defined by parent-child relations among dimension members. Circularity occurs when a dimension member is specified as its own ancestor or descendant.

- **Hierarchy type:** Hierarchies can be level based or value based. You can define a cube so that only level-based hierarchies are valid, such as a cube materialized view.
- **Level options:** Level-based hierarchies can be regular, ragged, or skip level. You can define a dimension so that only regular hierarchies are valid, such as a Time dimension.

The default name of the Cube Dimension Compile log is `CUBE_DIMENSION_COMPILE`. The following table describes its contents.

| Column           | Datatype       | NULL     | Description                             |
|------------------|----------------|----------|-----------------------------------------|
| ID               | NUMBER         | --       | Current operation identifier            |
| SEQ_NUMBER       | NUMBER         | --       | Sequence number in the Cube Build log   |
| ERROR#           | NUMBER(8)      | NOT NULL | Number of the error being reported      |
| ERROR_MESSAGE    | VARCHAR2(2000) | --       | Error message associated with the error |
| DIMENSION        | VARCHAR2(100)  | --       | Name of the dimension being compiled    |
| DIMENSION_MEMBER | VARCHAR2(100)  | --       | Faulty dimension member                 |
| MEMBER_ANCESTOR  | VARCHAR2(100)  | --       | Parent of <code>DIMENSION_MEMBER</code> |
| HIERARCHY1       | VARCHAR2(100)  | --       | First hierarchy involved in the error   |
| HIERARCHY2       | VARCHAR2(100)  | --       | Second hierarchy involved in the error  |
| ERROR_CONTEXT    | CLOB           | --       | Additional information about the error  |

## 47.1.8 DBMS\_CUBE\_LOG — Cube Operations Log

The Cube Operations log contains messages and debugging information for all OLAP engine events. You can track current operations at a very detailed level. Using the `SQL_ID` column, you can join the Cube Operations log to dynamic performance views such as `V$SQL`, `V$SESSION`, and `V$SESSION_LONGOPS` to see cube operations in the context of other database operations such as I/O Wait and CPU.

The default name of the Cube Operations log is `CUBE_OPERATIONS_LOG`. The following table describes its contents.

| Column     | Datatype                    | NULL     | Description                                                                                     |
|------------|-----------------------------|----------|-------------------------------------------------------------------------------------------------|
| INST_ID    | NUMBER                      | NOT NULL | Instance identifier                                                                             |
| SID        | NUMBER                      | NOT NULL | Session identifier                                                                              |
| SERIAL#    | NUMBER                      | NOT NULL | Session serial number                                                                           |
| USER#      | NUMBER                      | NOT NULL | User identifier                                                                                 |
| SQL_ID     | VARCHAR2(13)                | --       | Executing SQL statement identifier                                                              |
| JOB        | NUMBER                      | --       | Job identifier                                                                                  |
| ID         | NUMBER                      | --       | Current operation identifier                                                                    |
| PARENT_ID  | NUMBER                      | --       | Parent operation identifier                                                                     |
| SEQ_NUMBER | NUMBER                      | --       | Sequence number in the Cube Build log                                                           |
| TIME       | TIMESTAMP(6) WITH TIME ZONE | NOT NULL | Time the record was added to the Cube Operations log                                            |
| LOG_LEVEL  | NUMBER(4)                   | NOT NULL | Verbosity level of the record, as specified by the <code>DBMS_CUBE_LOG.ENABLE</code> procedure. |

| Column       | Datatype        | NULL     | Description                                                                                                                                                    |
|--------------|-----------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEPTH        | NUMBER (4)      | --       | Nesting depth of the record. For example, a level of 0 indicates that the operation and suboperation are not nested within other operations and suboperations. |
| OPERATION    | VARCHAR2 (15)   | NOT NULL | Current operation, such as AGGREGATE, ROWSOURCE, or SQLIMPORT.                                                                                                 |
| SUBOPERATION | VARCHAR2 (20)   | --       | Current suboperation, such as Loading or Import                                                                                                                |
| STATUS       | VARCHAR2 (10)   | NOT NULL | Current status of the operation, such as START, TRACE, COMPLETED, or Failed.                                                                                   |
| NAME         | VARCHAR2 (20)   | NOT NULL | Name of the record, such as ROWS LOADED, AVE_ROW_LEN, and PAGEPOOLSIZE                                                                                         |
| VALUE        | VARCHAR2 (4000) | --       | Value of NAME                                                                                                                                                  |
| DETAILS      | CLOB            | --       | Additional information about NAME.                                                                                                                             |

### 47.1.9 DBMS\_CUBE\_LOG — Cube Rejected Records Log

The Cube Rejected Records log contains a summary of the loader job and any records that were rejected because they did not meet the expected format.

A single row in the source table may have errors in more than one field. Each field generates an error in the log, resulting in multiple rows with the same rowid4

in the SOURCE\_ROW column.

The default name of the Cube Rejected Records log is CUBE\_REJECTED\_RECORDS. The following table describes its contents.

| Column        | Datatype    | NULL     | Description                                                                     |
|---------------|-------------|----------|---------------------------------------------------------------------------------|
| ID            | NUMBER      | --       | Current operation identifier                                                    |
| SEQ_NUMBER    | NUMBER      | --       | Sequence number in the Cube Build log                                           |
| ERROR#        | NUMBER (8)  | NOT NULL | Number of the error triggered by the record                                     |
| ERROR_MESSAGE | VARCHAR2    | --       | Error message associated with the error                                         |
| RECORD#       | NUMBER (38) | --       | Input record number                                                             |
| SOURCE_ROW    | ROWID       | --       | Rowid of the row in the source table; null when the source is a view or a query |

## 47.2 Summary of DBMS\_CUBE\_LOG Subprograms

This table lists and describes the DBMS\_CUBE\_LOG subprograms.

**Table 47-1 DBMS\_CUBE\_LOG Subprograms**

| Subprogram                            | Description                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DEFAULT_NAME Function</a> | Returns the default table names of the various log types.                                                                                  |
| <a href="#">DISABLE Procedure</a>     | Turns logging off for the duration of a session.                                                                                           |
| <a href="#">ENABLE Procedure</a>      | Turns on logging for the duration of a session, redirects logging to additional output types, and changes the verbosity level in the logs. |

**Table 47-1 (Cont.) DBMS\_CUBE\_LOG Subprograms**

| Subprogram                                      | Description                                                                                              |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">FLUSH Procedure</a>                 | Forces all buffered messages to be written to the logs.                                                  |
| <a href="#">GET_LOG Procedure</a>               | Returns the current settings for the level and location of a particular log.                             |
| <a href="#">GET_LOG_SPEC Function</a>           | Retrieves a description of all active logs.                                                              |
| <a href="#">GET_PARAMETER Function</a>          | Returns the current values of the options that control various aspects of logging.                       |
| <a href="#">LEVEL_HIGH Function</a>             | Returns the integer value of the high verbosity level.                                                   |
| <a href="#">LEVEL_HIGHEST Function</a>          | Returns the integer value of the highest verbosity level.                                                |
| <a href="#">LEVEL_LOW Function</a>              | Returns the integer value of the low verbosity level.                                                    |
| <a href="#">LEVEL_LOWEST Function</a>           | Returns the integer value of the lowest verbosity level.                                                 |
| <a href="#">LEVEL_MEDIUM Function</a>           | Returns the integer value of the medium verbosity level.                                                 |
| <a href="#">SET_LOG_SPEC Procedure</a>          | Sets all logging to the values specified in the input string.                                            |
| <a href="#">SET_PARAMETER Procedure</a>         | Sets options that control various aspects of logging.                                                    |
| <a href="#">TABLE_CREATE Procedure</a>          | Creates the table targets for the OLAP logs.                                                             |
| <a href="#">TARGET_FILE Function</a>            | Returns the integer value of a disk file target.                                                         |
| <a href="#">TARGET_LOB Function</a>             | Returns the integer value of a LOB target.                                                               |
| <a href="#">TARGET_TABLE Function</a>           | Returns the integer value of a database table target                                                     |
| <a href="#">TARGET_TRACE Function</a>           | Returns the integer value of a trace file target.                                                        |
| <a href="#">TYPE_BUILD Function</a>             | Returns the integer value of the Cube Build log.                                                         |
| <a href="#">TYPE_DIMENSION_COMPILE Function</a> | Returns the integer value of the Cube Dimension Compile log.                                             |
| <a href="#">TYPE_OPERATIONS Function</a>        | Returns the integer value of the Cube Operations log.                                                    |
| <a href="#">TYPE_REJECTED_RECORDS Function</a>  | Returns the integer value of the Cube Rejected Records log.                                              |
| <a href="#">VERSION Function</a>                | Returns the version number of a specific log table or the current version number of a specific log type. |

## 47.2.1 DEFAULT\_NAME Function

This function returns the default table names of the various log types.

### Syntax

```
DBMS_CUBE_LOG.DEFAULT_NAME (
    LOG_TYPE          IN    BINARY_INTEGER  DEFAULT TYPE_OPERATIONS)
RETURN VARCHAR2;
```

## Parameters

**Table 47-2 DEFAULT\_NAME Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type  | <p>One of the following log types:</p> <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> <li>4: TYPE_BUILD</li> </ul> <p>See "<a href="#">Logging Types</a>".</p> |

## Returns

The default table name of the specified log type.

## Examples

This example returns the default name of the Cube Operations log:

```
SELECT dbms_cube_log.default_name FROM dual;
```

```
DEFAULT_NAME
-----
CUBE_OPERATIONS_LOG
```

The next example returns the default name of the Cube Rejected Records log:

```
select dbms_cube_log.default_name(dbms_cube_log.type_rejected_records) -
       "Default Name" from dual;
```

```
Default Name
-----
CUBE_REJECTED_RECORDS
```

## 47.2.2 DISABLE Procedure

This procedure turns logging off for the duration of a session, unless logging is explicitly turned on again with the `ENABLE` procedure.

### Syntax

```
DBMS_CUBE_LOG.DISABLE (
    LOG_TYPE      IN  BINARY_INTEGER  DEFAULT,
    LOG_TARGET     IN  BINARY_INTEGER  DEFAULT);
```

## Parameters

**Table 47-3** DISABLE Procedure Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type   | <p>One of the following log types:</p> <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> </ul> <p><b>Note:</b> You cannot disable the Cube Build log with this procedure.<br/>See "<a href="#">Logging Types</a>".</p>                                                              |
| log_target | <p>One of the following destinations for the logging records. The logs are sent to a table unless you previously specified a different target using the ENABLE procedure.</p> <ul style="list-style-type: none"> <li>1: TARGET_TABLE</li> <li>2: TARGET_TRACE</li> <li>3: TARGET_FILE</li> <li>4: TARGET_LOB</li> </ul> <p>See "<a href="#">Logging Targets</a>".</p> |

## Example

This command disables the dimension compilation error log table:

```
EXECUTE dbms_cube_log.disable(dbms_cube_log.type_dimension_compile);
```

## 47.2.3 ENABLE Procedure

This procedure turns on logging for the duration of a session or until it is turned off using the DISABLE procedure.

The ENABLE procedure also allows you to direct logging to additional output types and to change the amount of detail in the logs. You can enable a log type to each of the log targets. For example, you can enable the Cube Operations log to the trace file, a table, and a file at different verbosity levels, but you cannot enable the Cube Operations log to two files at the same time.

This procedure also checks the format of the logs and updates them if necessary.

## Syntax

```
DBMS_CUBE_LOG.ENABLE (
    LOG_TYPE      IN      BINARY_INTEGER DEFAULT NULL,
    LOG_TARGET     IN      BINARY_INTEGER DEFAULT NULL,
    LOG_LEVEL      IN      BINARY_INTEGER DEFAULT NULL);

DBMS_CUBE_LOG.ENABLE (
    LOG_TYPE      IN      BINARY_INTEGER DEFAULT NULL,
    LOG_TARGET     IN      BINARY_INTEGER DEFAULT NULL,
    LOG_LEVEL      IN      BINARY_INTEGER DEFAULT NULL,
    LOG_LOCATION   IN      VARCHAR2      DEFAULT NULL);

DBMS_CUBE_LOG.ENABLE (
    LOG_TYPE      IN      BINARY_INTEGER DEFAULT NULL,
    LOG_TARGET     IN      BINARY_INTEGER DEFAULT NULL,
```

```
LOG_LEVEL      IN      BINARY_INTEGER  DEFAULT NULL,
LOG_LOCATION   IN/OUT CLOB );
```

## Parameters

**Table 47-4** ENABLE Procedure Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type     | <p>One of the following log types:</p> <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> </ul> <p><b>Note:</b> You cannot disable the Cube Build log with this procedure. See "<a href="#">Logging Types</a>".</p>                                                                  |
| log_target   | <p>One of the following destinations for the logging records. The logs are sent to a table unless you previously specified a different target using the ENABLE procedure.</p> <ul style="list-style-type: none"> <li>1: TARGET_TABLE</li> <li>2: TARGET_TRACE</li> <li>3: TARGET_FILE</li> <li>4: TARGET_LOB</li> </ul> <p>See "<a href="#">Logging Targets</a>".</p> |
| log_level    | <p>One of the following log verbosity levels. Each level adds new types of messages to the previous level.</p> <ul style="list-style-type: none"> <li>1: LEVEL_LOWEST</li> <li>2: LEVEL_LOW</li> <li>3: LEVEL_MEDIUM</li> <li>4: LEVEL_HIGH</li> <li>5: LEVEL_HIGHEST</li> </ul> <p>See "<a href="#">Verbosity Levels</a>".</p>                                       |
| log_location | <p>The full identity of the log, such as <i>owner.table_name</i> when log_target is a table.</p>                                                                                                                                                                                                                                                                      |

## Examples

The following command enables all cube logs:

```
EXECUTE dbms_cube_log.enable;
```

The following PL/SQL procedure sets the log level to LEVEL\_LOWEST:

```
BEGIN
    dbms_cube_log.disable(dbms_cube_log.type_rejected_records);
    dbms_cube_log.enable(dbms_cube_log.type_rejected_records,
        dbms_cube_log.target_table, dbms_cube_log.level_lowest);
END;
```

## 47.2.4 FLUSH Procedure

This procedure forces all buffered messages to be written to the logs.

The buffers are flushed automatically throughout a session, but manually flushing them before viewing the logs assures that you can view all of the messages.

Syntax

```
DBMS_CUBE_LOG.FLUSH ( );
```

Example

The following example flushes the buffers for all of the logs:

```
EXECUTE dbms_cube_log.flush;
```

47.2.5 GET\_LOG Procedure

This procedure returns the current settings for the level and location of a particular log.

Syntax

```
DBMS_CUBE_LOG.GET_LOG (
    LOG_TYPE      IN  BINARY_INTEGER  DEFAULT TYPE_OPERATIONS,
    LOG_TARGET     IN  BINARY_INTEGER  DEFAULT TARGET_TABLE,
    LOG_LEVEL      OUT BINARY_INTEGER,
    LOG_LOCATION   OUT  VARCHAR2 );
```

Parameters

Table 47-5 GET\_LOG Procedure Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type     | One of the following log types: <ul style="list-style-type: none"><li>1: TYPE_OPERATIONS</li><li>2: TYPE_REJECTED_RECORDS</li><li>3: TYPE_DIMENSION_COMPILE</li></ul> See " <a href="#">Logging Types</a> ".                                                                                                                                         |
| log_target   | One of the following destinations for the logging records. The logs are sent to a table unless you previously specified a different target using the ENABLE procedure. <ul style="list-style-type: none"><li>1: TARGET_TABLE</li><li>2: TARGET_TRACE</li><li>3: TARGET_FILE</li><li>4: TARGET_LOB</li></ul> See " <a href="#">Logging Targets</a> ". |
| log_level    | One of the following log verbosity levels. Each level adds new types of messages to the previous level. <ul style="list-style-type: none"><li>1: LEVEL_LOWEST</li><li>2: LEVEL_LOW</li><li>3: LEVEL_MEDIUM</li><li>4: LEVEL_HIGH</li><li>5: LEVEL_HIGHEST</li></ul> See " <a href="#">Verbosity Levels</a> ".                                        |
| log_location | The full identity of the log, such as <i>owner.table_name</i> when log_target is a table.                                                                                                                                                                                                                                                            |

## Usage Notes

If `log_type` is not active, then `log_level` and `log_location` are null. Use `DBMS_CUBE_LOG.ENABLE` to activate a log.

## Examples

This PL/SQL procedure provides information about the Cube Rejected Records log:

```
SET serverout ON format wrapped

DECLARE
    myloglevel  binary_integer;
    mylogtarget varchar2(128);

BEGIN
    dbms_cube_log.get_log(dbms_cube_log.type_rejected_records,
        dbms_cube_log.target_table, myloglevel, mylogtarget);

    dbms_output.put_line('Log Level: ' || myloglevel);
    dbms_output.put_line('Log Target: ' || mylogtarget);
END;
/
```

The procedure generates results like the following:

```
Log Level: 5

Log Target: GLOBAL.CUBE_REJECTED_RECORDS
```

## 47.2.6 GET\_LOG\_SPEC Function

This function retrieves a description of all active Cube Operations logs, Cube Rejected Records logs, and Cube Dimension Compile logs.

### Syntax

```
DBMS_CUBE_LOG.GET_LOG_SPEC ( )
    RETURN VARCHAR2;
```

### Returns

The type and target of all active logs.

### Usage Notes

You can use the output from this function as the input to `SET_LOG_SPEC`.

## Examples

The following example shows that the Cube Operations log, Cube Rejected Records log, and Cube Dimension Compile log are active. The Cube Operations log is stored in the session trace file and the other logs are stored in tables.

```
SELECT dbms_cube_log.get_log_spec FROM dual;

GET_LOG_SPEC
-----
OPERATIONS(TABLE, TRACE) REJECTED_RECORDS(TABLE[DEBUG])
```

## 47.2.7 GET\_PARAMETER Function

This function returns the current values of the options that control various aspects of logging. To set these options, use the `SET_PARAMETER` function.

### Syntax

```
DBMS_CUBE_LOG.GET_PARAMETER (
    LOG_TYPE      IN   BINARY_INTEGER,
    LOG_PARAMETER IN   BINARY_INTEGER )
RETURN BINARY_INTEGER;
```

### Parameters

**Table 47-6 GET\_PARAMETER Function Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                            |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>log_type</code>      | One of the following log types: <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> </ul> See " <a href="#">Logging Types</a> ".                                       |
| <code>log_parameter</code> | One of the following options: <ul style="list-style-type: none"> <li>1: MAX_ERRORS</li> <li>2: FLUSH_INTERVAL</li> <li>3: LOG_FULL_RECORD</li> <li>4: LOG_EVERY_N</li> <li>5: ALLOW_ERRORS</li> </ul> See " <a href="#">SET_PARAMETER Procedure</a> ". |

### Returns

The value of the specified `log_parameter`.

### Examples

This example shows the current maximum number of errors in the Cube Rejected Records log before logging stops. This parameter was previously set with the `SET_PARAMETER` procedure.

```
SELECT dbms_cube_log.get_parameter(dbms_cube_log.type_rejected_records, 1) -
       "Maximum Records" FROM dual;
```

```
Maximum Records
-----
              100
```

## 47.2.8 LEVEL\_HIGH Function

This function returns the integer value of the high verbosity level.

### Syntax

```
DBMS_CUBE_LOG.LEVEL_HIGH ()
RETURN BINARY_INTEGER;
```

### Returns

4

### Usage Notes

Use this function instead of its binary integer equivalent for the `LOG_LEVEL` parameter in DBMS\_CUBE\_LOG subprograms. See "[Verbosity Levels](#)".

### Example

This command sets the verbosity level of the cube operations table to high:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations, -
                             dbms_cube_log.target_table, dbms_cube_log.level_high);
```

## 47.2.9 LEVEL\_HIGHEST Function

This function returns the integer value of the highest verbosity level.

### Syntax

```
DBMS_CUBE_LOG.LEVEL_HIGHEST ()
    RETURN BINARY_INTEGER;
```

### Returns

5

### Usage Notes

Use this function instead of its binary integer equivalent for the `LOG_LEVEL` parameter in DBMS\_CUBE\_LOG subprograms. See "[Verbosity Levels](#)".

### Example

This command sets the verbosity level of the cube operations table to highest:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations, -
                             dbms_cube_log.target_table, dbms_cube_log.level_highest);
```

## 47.2.10 LEVEL\_LOW Function

This function returns the integer value of the low verbosity level.

### Syntax

```
DBMS_CUBE_LOG.LEVEL_LOW ()
    RETURN BINARY_INTEGER;
```

### Returns

2

### Usage Notes

Use this function instead of its binary integer equivalent for the `LOG_LEVEL` parameter in DBMS\_CUBE\_LOG subprograms. See "[Verbosity Levels](#)".

### Example

This command sets the verbosity level of the cube operations table to low:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations, -
                             dbms_cube_log.target_table, dbms_cube_log.level_low);
```

## 47.2.11 LEVEL\_LOWEST Function

This function returns the integer value of the lowest verbosity level. This level logs the status of each command used to build the cube dimensions and cubes, the use of slave processes, and summary records.

### Syntax

```
DBMS_CUBE_LOG.LEVEL_LOWEST ()
    RETURN BINARY_INTEGER;
```

### Returns

1

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_LEVEL parameter in DBMS\_CUBE\_LOG subprograms. See "[Verbosity Levels](#)".

### Example

This command sets the verbosity level of the cube operations table to lowest:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations, -
                             dbms_cube_log.target_table, dbms_cube_log.level_lowest);
```

## 47.2.12 LEVEL\_MEDIUM Function

This function returns the integer value of the medium verbosity level.

### Syntax

```
DBMS_CUBE_LOG.LEVEL_MEDIUM ()
    RETURN BINARY_INTEGER;
```

### Returns

3

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_LEVEL parameter in DBMS\_CUBE\_LOG subprograms. See "[Verbosity Levels](#)".

### Example

This command sets the verbosity level of the cube operations table to medium:

```
EXECUTE dbms_cube_log.enable(dbms_cube_log.type_operations, -
                             dbms_cube_log.target_table, dbms_cube_log.level_medium);
```

## 47.2.13 SET\_LOG\_SPEC Procedure

This procedure sets all logging to the values specified in the input string.

### Syntax

```
DBMS_CUBE_LOG.SET_LOG_SPEC (
    LOG_SPEC      IN   VARCHAR2 );
```

### Parameters

**Table 47-7 SET\_LOG\_SPEC Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_spec  | <p>A string consisting of <i>type(target)</i> pairs.</p> <p><i>Type</i> can be:</p> <ul style="list-style-type: none"> <li>• OPERATIONS</li> <li>• REJECTED_RECORDS</li> <li>• DIMENSION_COMPILE</li> </ul> <p><i>Target</i> can be:</p> <ul style="list-style-type: none"> <li>• TABLE</li> <li>• TRACE</li> <li>• FILE</li> <li>• LOB</li> </ul> |

### Usage Notes

The GET\_LOG\_SPEC function returns a properly formatted string for SET\_LOG\_SPEC.

### Examples

This PL/SQL procedure disables all logs, verifies that they are disabled, then activates the Cube Operations log and the Cube Rejected Records log.

```
BEGIN
    dbms_cube_log.disable;
    dbms_output.put_line('Cube Logs: ' || dbms_cube_log.get_log_spec);

    dbms_cube_log.set_log_spec('OPERATIONS(TRACE) REJECTED_RECORDS(TABLE)');
    dbms_output.put_line('Cube Logs: ' || dbms_cube_log.get_log_spec);
END;
/
```

The output from the procedure verifies that the DISABLE function de-activated all logs, and the SET\_LOG\_SPEC function activated two logs:

Cube Logs:

Cube Logs: OPERATIONS(TRACE) REJECTED\_RECORDS(TABLE)

## 47.2.14 SET\_PARAMETER Procedure

This procedure sets options that control various aspects of logging.

To obtain the current value of these options, use the GET\_PARAMETER function.

## Syntax

```
DBMS_CUBE_LOG.SET_PARAMETER (
    LOG_TYPE      IN  BINARY_INTEGER,
    LOG_PARAMETER IN  BINARY_INTEGER,
    VALUE         IN  BINARY_INTEGER );
```

## Parameters

**Table 47-8 SET\_PARAMETER Procedure Parameters**

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type      | <p>One of the following log types:</p> <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> <li>4: TYPE_BUILD</li> </ul> <p>See "<a href="#">Logging Types</a>".</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| log_parameter | <p>One of the following parameters:</p> <ul style="list-style-type: none"> <li>1: MAX_ERRORS<br/>Maximum number of records before signalling an end to logging, such as the number of rejected records in the Cube Rejected Records log or the number of compilation errors in the dimension compilation error log.</li> <li>2: FLUSH_INTERVAL<br/>The number of seconds to buffer the records before writing them to a log. When this parameter is 0, the records are written directly to the logs without buffering.</li> <li>3: LOG_FULL_RECORD<br/>Controls logging of rejected records. Set this parameter to one of the following constants:<br/>0: FULL_RECORD_AUTO: Log the full record when no row ID is available.<br/>1: FULL_RECORD_ALWAYS: Always log the full record.<br/>2: FULL_RECORD_NEVER: Never log the full record.</li> <li>4: LOG_EVERY_N<br/>Enters a progress message every <i>n</i> rows during data maintenance.</li> <li>5: ALLOW_ERRORS: Displays logging errors, which are initially turned off to allow processing to proceed.</li> </ul> |
| value         | The new value of <i>log_parameter</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Examples

This PL/SQL procedure sets the two parameters, then uses the `GET_PARAMETER` function to show the settings:

```
BEGIN
    dbms_cube_log.set_parameter(dbms_cube_log.type_rejected_records, 1, 150);
    dbms_cube_log.set_parameter(dbms_cube_log.type_rejected_records, 2, 5);

    dbms_output.put_line('Max rejected records: ' ||
        dbms_cube_log.get_parameter(dbms_cube_log.type_rejected_records, 1));
```

```

        dbms_output.put_line('Buffer time: ' ||
        dbms_cube_log.get_parameter(dbms_cube_log.type_rejected_records, 2) ||
        ' seconds');
END;
/

```

The procedure displays this information:

Max rejected records: 150

Buffer time: 5 seconds

## 47.2.15 TABLE\_CREATE Procedure

This procedure creates the table targets for the OLAP logs. You must have the `CREATE TABLE` privilege to use this procedure.

`TABLE_CREATE` also upgrades existing log tables to the current version while preserving the data.

### Syntax

```

DBMS_CUBE_LOG.TABLE_CREATE (
    LOG_TYPE      IN   BINARY_INTEGER  DEFAULT,
    TBLNAME       IN   VARCHAR2        DEFAULT );

```

### Parameters

**Table 47-9 TABLE\_CREATE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type  | One of the following log types: <ul style="list-style-type: none"> <li>1: TYPE_OPERATIONS</li> <li>2: TYPE_REJECTED_RECORDS</li> <li>3: TYPE_DIMENSION_COMPILE</li> <li>4: TYPE_BUILD</li> </ul> See " <a href="#">Logging Types</a> ". |
| tblname   | A table name for the log. These are the default names: <ul style="list-style-type: none"> <li>CUBE_OPERATIONS_LOG</li> <li>CUBE_REJECTED_RECORDS</li> <li>CUBE_DIMENSION_COMPILE</li> <li>CUBE_BUILD_LOG</li> </ul>                     |

### Examples

This example creates a Cube Operations log table named `CUBE_OPERATIONS_LOG`:

```
EXECUTE dbms_cube_log.table_create;
```

This example creates a Cube Rejected Records log table named `CUBE_REJECTED_RECORDS`:

```
EXECUTE dbms_cube_log.table_create(dbms_cube_log.type_rejected_records);
```

The next example creates a Cube Build log table named `MY_BUILD_LOG`:

```
EXECUTE dbms_cube_log.table_create -
    (dbms_cube_log.type_build, 'MY_BUILD_LOG');
```

## 47.2.16 TARGET\_FILE Function

This function returns the integer value of a file target in DBMS\_CUBE\_LOG subprograms.

### Syntax

```
DBMS_CUBE_LOG.TARGET_FILE ()  
    RETURN BINARY_INTEGER;
```

### Returns

3

### Usage Notes

Use this function instead of its binary integer equivalent for the *LOG\_LEVEL* parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Targets"](#).

### Example

This command disables the Cube Operations log file:

```
EXECUTE dbms_cube_log.disable -  
    (dbms_cube_log.type_operations, dbms_cube_log.target_file);
```

## 47.2.17 TARGET\_LOB Function

This function returns the integer value of a LOB target.

### Syntax

```
DBMS_CUBE_LOG.TARGET_LOB ()  
    RETURN BINARY_INTEGER;
```

### Returns

4

### Usage Notes

Use this function instead of its binary integer equivalent for the *LOG\_LEVEL* parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Targets"](#).

### Example

This command disables the Cube Operations log LOB:

```
EXECUTE dbms_cube_log.disable -  
    (dbms_cube_log.type_operations, dbms_cube_log.target_lob);
```

## 47.2.18 TARGET\_TABLE Function

This function returns the integer value of a table target.

### Syntax

```
DBMS_CUBE_LOG.TARGET_TABLE ()  
    RETURN BINARY_INTEGER;
```

### Returns

1

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TARGET parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Targets"](#).

### Example

This command disables the Cube Operations log table:

```
EXECUTE dbms_cube_log.disable -  
        (dbms_cube_log.type_operations, dbms_cube_log.target_table);
```

## 47.2.19 TARGET\_TRACE Function

This function returns the integer value of a trace file target.

### Syntax

```
DBMS_CUBE_LOG.TARGET_TRACE ()  
    RETURN BINARY_INTEGER;
```

### Returns

2

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TARGET parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Targets"](#).

### Example

This command disables the Cube Operations log trace file:

```
EXECUTE dbms_cube_log.disable -  
        (dbms_cube_log.type_operations, dbms_cube_log.target_trace);
```

## 47.2.20 TYPE\_BUILD Function

This function returns the integer value of the Cube Build log.

### Syntax

```
DBMS_CUBE_LOG.TYPE_BUILD ()  
    RETURN BINARY_INTEGER;
```

### Returns

4

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TYPE parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Types"](#).

### Example

This query returns the default name of a Cube Build log:

```
SELECT dbms_cube_log.default_name(dbms_cube_log.type_build) "Log Name" -
       FROM dual;

Log Name
-----
CUBE_BUILD_LOG
```

## 47.2.21 TYPE\_DIMENSION\_COMPILE Function

This function returns the integer value of the Cube Dimension Compile log.

### Syntax

```
DBMS_CUBE_LOG.TYPE_DIMENSION_COMPILE ()
RETURN BINARY_INTEGER;
```

### Returns

3

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TYPE parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Types"](#).

### Example

This query returns the default name of a Cube Dimension Compile log:

```
SELECT dbms_cube_log.default_name(dbms_cube_log.type_dimension_compile) -
       "Log Name" FROM dual;

Log Name
-----
CUBE_DIMENSION_COMPILE
```

## 47.2.22 TYPE\_OPERATIONS Function

This function returns the integer value of the Cube Operations log.

### Syntax

```
DBMS_CUBE_LOG.TYPE_OPERATIONS ()
RETURN BINARY_INTEGER;
```

### Returns

1

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TYPE parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Types"](#).

### Example

This query returns the default name of a Cube Dimension Compile log:

```
SELECT dbms_cube_log.default_name(dbms_cube_log.type_operations) "Log Name" -
       FROM dual;
```

```
Log Name
-----
CUBE_OPERATIONS_LOG
```

## 47.2.23 TYPE\_REJECTED\_RECORDS Function

This function returns the integer value of the cube Cube Rejected Records log.

### Syntax

```
DBMS_CUBE_LOG.TYPE_REJECTED_RECORDS (
    RETURN BINARY_INTEGER;
```

### Returns

2

### Usage Notes

Use this function instead of its binary integer equivalent for the LOG\_TYPE parameter in DBMS\_CUBE\_LOG subprograms. See ["Logging Types"](#).

### Example

This query returns the default name of a Cube Rejected Records log:

```
SELECT dbms_cube_log.default_name(dbms_cube_log.type_rejected_records) -
       "Log Name" FROM dual;
```

```
Log Name
-----
CUBE_REJECTED_RECORDS
```

## 47.2.24 VERSION Function

This function returns the version number of a specific log table or the current version number of a specific log type.

### Syntax

```
DBMS_CUBE_LOG.VERSION (
    LOG_TYPE      IN  BINARY_INTEGER  DEFAULT 1,
    TBLNAME       IN  VARCHAR2        DEFAULT NULL)
RETURN BINARY_INTEGER;
```

## Parameters

**Table 47-10** VERSION Function Parameters

| Parameter | Description                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_type  | One of the following log types: <ul style="list-style-type: none"> <li>• 1: TYPE_OPERATIONS</li> <li>• 2: TYPE_REJECTED_RECORDS</li> <li>• 3: TYPE_DIMENSION_COMPILE</li> <li>• 4: TYPE_BUILD</li> </ul> See " <a href="#">Logging Types</a> ". |
| tblname   | The name of the log table whose version is returned.                                                                                                                                                                                            |

## Returns

A version number

## Examples

This example returns the current version of the Cube Operations log:

```
SELECT dbms_cube_log.version FROM dual;
```

```

VERSION
-----
      2
```

This example returns the version number of an existing Cube Rejected Records log named CUBE\_REJECTED\_RECORDS.

```
SELECT dbms_cube_log.version(dbms_cube_log.type_rejected_records, -
    'CUBE_REJECTED_RECORDS') version FROM dual;
```

```

VERSION
-----
      2
```

# DBMS\_DATA\_MINING

The `DBMS_DATA_MINING` package is the application programming interface for creating, evaluating, and querying data mining models.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Mining Functions](#)
- [Model Settings](#)
- [Solver Settings](#)
- [Datatypes](#)
- [Summary of DBMS\\_DATA\\_MINING Subprograms](#)

## See Also:

- [DBMS\\_DATA\\_MINING\\_TRANSFORM](#)
- [DBMS\\_PREDICTIVE\\_ANALYTICS](#)

## 48.1 DBMS\_DATA\_MINING Overview

Oracle Data Mining supports both supervised and unsupervised data mining. Supervised data mining predicts a target value based on historical data. Unsupervised data mining discovers natural groupings and does not use a target. You can use Oracle Data Mining to mine structured data and unstructured text.

Supervised data mining functions include:

- Classification
- Regression
- Feature Selection (Attribute Importance)

Unsupervised data mining functions include:

- Clustering
- Association
- Feature Extraction
- Anomaly Detection

The steps you use to build and apply a mining model depend on the data mining function and the algorithm being used. The algorithms supported by Oracle Data Mining are listed in [Table 48-1](#).

**Table 48-1 Oracle Data Mining Algorithms**

| Algorithm                                                     | Abbreviation | Function                                      |
|---------------------------------------------------------------|--------------|-----------------------------------------------|
| Apriori                                                       | AR           | Association                                   |
| CUR Matrix Decomposition                                      | CUR          | Attribute Importance                          |
| Decision Tree                                                 | DT           | Classification                                |
| Expectation Maximization                                      | EM           | Clustering                                    |
| Explicit Semantic Analysis                                    | ESA          | Feature Extraction, Classification            |
| Exponential Smoothing                                         | ESM          | Time Series                                   |
| Generalized Linear Model                                      | GLM          | Classification, Regression                    |
| <i>k</i> -Means                                               | KM           | Clustering                                    |
| Minimum Descriptor Length                                     | MDL          | Attribute Importance                          |
| Naive Bayes                                                   | NB           | Classification                                |
| Neural Networks                                               | NN           | Classification, Regression                    |
| Non-Negative Matrix Factorization                             | NMF          | Feature Extraction                            |
| Orthogonal Partitioning Clustering                            | O-Cluster    | Clustering                                    |
| Random Forest                                                 | RF           | Classification                                |
| Singular Value Decomposition and Principal Component Analysis | SVD and PCA  | Feature Extraction                            |
| Support Vector Machine                                        | SVM          | Classification, Regression, Anomaly Detection |

Oracle Data Mining supports more than one algorithm for the classification, regression, clustering, and feature extraction mining functions. Each of these mining functions has a default algorithm, as shown in [Table 48-2](#).

**Table 48-2 Oracle Data Mining Default Algorithms**

| Mining Function    | Default Algorithm                 |
|--------------------|-----------------------------------|
| Classification     | Naive Bayes                       |
| Clustering         | <i>k</i> -Means                   |
| Feature Extraction | Non-Negative Matrix Factorization |
| Feature Selection  | Minimum Descriptor Length         |
| Regression         | Support Vector Machine            |

## 48.2 DBMS\_DATA\_MINING Security Model

The `DBMS_DATA_MINING` package is owned by user `SYS` and is installed as part of database installation. Execution privilege on the package is granted to public. The routines in the package are run with invokers' rights (run with the privileges of the current user).

The `DBMS_DATA_MINING` package exposes APIs that are leveraged by the Oracle Data Mining component of the Advanced Analytics Option. Users who wish to create mining models in their

own schema require the `CREATE MINING MODEL` system privilege. Users who wish to create mining models in other schemas require the `CREATE ANY MINING MODEL` system privilege.

Users have full control over managing models that exist within their own schema. Additional system privileges necessary for managing data mining models in other schemas include `ALTER ANY MINING MODEL`, `DROP ANY MINING MODEL`, `SELECT ANY MINING MODEL`, `COMMENT ANY MINING MODEL`, and `AUDIT ANY`.

Individual object privileges on mining models, `ALTER MINING MODEL` and `SELECT MINING MODEL`, can be used to selectively grant privileges on a model to a different user.

## 48.3 DBMS\_DATA\_MINING — Mining Functions

A data mining **function** refers to the methods for solving a given class of data mining problems.

The mining function must be specified when a model is created. (See [CREATE\\_MODEL Procedure](#).)

**Table 48-3 Mining Functions**

| Value                | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ASSOCIATION          | Association is a descriptive mining function. An association model identifies relationships and the probability of their occurrence within a data set.<br>Association models use the Apriori algorithm.                                                                                                                                                                                                                           |
| ATTRIBUTE_IMPORTANCE | Attribute importance is a predictive mining function, also known as feature selection. An attribute importance model identifies the relative importance of an attribute in predicting a given outcome.<br>Attribute importance models can use Minimum Description Length, or CUR Matrix Decomposition. Minimum Description Length is the default.                                                                                 |
| CLASSIFICATION       | Classification is a predictive mining function. A classification model uses historical data to predict a categorical target.<br>Classification models can use: Naive Bayes, Decision Tree, Logistic Regression, or Support Vector Machine. The default is Naive Bayes.<br>The classification function can also be used for <b>anomaly detection</b> . In this case, the SVM algorithm with a null target is used (One-Class SVM). |
| CLUSTERING           | Clustering is a descriptive mining function. A clustering model identifies natural groupings within a data set.<br>Clustering models can use <i>k</i> -Means, O-Cluster, or Expectation Maximization. The default is <i>k</i> -Means.                                                                                                                                                                                             |

**Table 48-3 (Cont.) Mining Functions**

| Value              | Description                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_EXTRACTION | Feature Extraction is a descriptive mining function. A feature extraction model creates an optimized data set on which to base a model.<br>Feature extraction models can use Explicit Semantic Analysis, Non-Negative Matrix Factorization, Singular Value Decomposition, or Principal Component Analysis. Non-Negative Matrix Factorization is the default. |
| REGRESSION         | Regression is a predictive mining function. A regression model uses historical data to predict a numerical target.<br>Regression models can use Support Vector Machine or Linear Regression. The default is Support Vector Machine.                                                                                                                          |
| TIME_SERIES        | Time series is a predictive mining function. A time series model forecasts the future values of a time-ordered series of historical numeric data over a user-specified time window. Time series models use the Exponential Smoothing algorithm.                                                                                                              |

**See Also:**

*Oracle Data Mining Concepts* for more information about mining functions

## 48.4 DBMS\_DATA\_MINING — Model Settings

Oracle Data Mining uses settings to specify the algorithm and other characteristics of a model. Some settings are general, some are specific to a mining function, and some are specific to an algorithm.

All settings have default values. If you want to override one or more of the settings for a model, you must create a settings table. The settings table must have the column names and datatypes shown in the following table.

**Table 48-4 Required Columns in the Model Settings Table**

| Column Name   | Datatype        |
|---------------|-----------------|
| SETTING_NAME  | VARCHAR2 (30)   |
| SETTING_VALUE | VARCHAR2 (4000) |

The information you provide in the settings table is used by the model at build time. The name of the settings table is an optional argument to the [CREATE\\_MODEL Procedure](#).

You can find the settings used by a model by querying the data dictionary view `ALL_MINING_MODEL_SETTINGS`. This view lists the model settings used by the mining models to which you have access. All the setting values are included in the view, whether default or user-specified.

 **See Also:**

- `ALL_MINING_MODEL_SETTINGS` in *Oracle Database Reference*
- *Oracle Data Mining User's Guide* for information about specifying model settings

## 48.4.1 DBMS\_DATA\_MINING — Algorithm Names

The `ALGO_NAME` setting specifies the model algorithm.

The values for the `ALGO_NAME` setting are listed in the following table.

**Table 48-5 Algorithm Names**

| ALGO_NAME Value                             | Description                            | Mining Function                                                   |
|---------------------------------------------|----------------------------------------|-------------------------------------------------------------------|
| <code>ALGO_AI_MDL</code>                    | Minimum Description Length             | Attribute Importance                                              |
| <code>ALGO_APRIORI_ASSOCIATION_RULES</code> | Apriori                                | Association Rules                                                 |
| <code>ALGO_CUR_DECOMPOSITION</code>         | CUR Decomposition                      | Attribute Importance                                              |
| <code>ALGO_DECISION_TREE</code>             | Decision Tree                          | Classification                                                    |
| <code>ALGO_EXPECTATION_MAXIMIZATION</code>  | Expectation Maximization               | Clustering                                                        |
| <code>ALGO_EXPLICIT_SEMANTIC_ANALYS</code>  | Explicit Semantic Analysis             | Feature Extraction<br>Classification                              |
| <code>ALGO_EXPONENTIAL_SMOOTHING</code>     | Exponential Smoothing                  | Time Series                                                       |
| <code>ALGO_EXTENSIBLE_LANG</code>           | Language used for extensible algorithm | All mining functions supported                                    |
| <code>ALGO_GENERALIZED_LINEAR_MODEL</code>  | Generalized Linear Model               | Classification, Regression; also Feature Selection and Generation |
| <code>ALGO_KMEANS</code>                    | Enhanced <i>k</i> _Means               | Clustering                                                        |
| <code>ALGO_NAIVE_BAYES</code>               | Naive Bayes                            | Classification                                                    |
| <code>ALGO_NEURAL_NETWORK</code>            | Neural Network                         | Classification                                                    |
| <code>ALGO_NONNEGATIVE_MATRIX_FACTOR</code> | Non-Negative Matrix Factorization      | Feature Extraction                                                |
| <code>ALGO_O_CLUSTER</code>                 | O-Cluster                              | Clustering                                                        |
| <code>ALGO_RANDOM_FOREST</code>             | Random Forest                          | Classification                                                    |
| <code>ALGO_SINGULAR_VALUE_DECOMP</code>     | Singular Value Decomposition           | Feature Extraction                                                |
| <code>ALGO_SUPPORT_VECTOR_MACHINES</code>   | Support Vector Machine                 | Classification and Regression                                     |

## 48.4.2 DBMS\_DATA\_MINING — Automatic Data Preparation

Oracle Data Mining for SQL supports fully Automatic Data Preparation (ADP), user-directed general data preparation, and user-specified embedded data preparation. The `PREP_*` settings enable the user to request fully automated or user-directed general data preparation. By default, fully Automatic Data Preparation (`PREP_AUTO_ON`) is enabled.

When you enable ADP, the model uses heuristics to transform the build data according to the requirements of the algorithm. Instead of fully ADP, the user can request that the data be shifted and/or scaled with the `PREP_SCALE*` and `PREP_SHIFT*` settings. The transformation instructions are stored with the model and reused whenever the model is applied. The model settings can be viewed in `USER_MINING_MODEL_SETTINGS`.

You can choose to supplement Automatic Data Preparations by specifying additional transformations in the `xform_list` parameter when you build the model. See "[CREATE\\_MODEL Procedure](#)" and "[CREATE\\_MODEL2 Procedure](#)".

If you do not use ADP *and* do not specify transformations in the `xform_list` parameter to `CREATE_MODEL`, you must implement your own transformations separately in the build, test, and scoring data. You must take special care to implement the exact same transformations in each data set.

If you do not use ADP, but you *do* specify transformations in the `xform_list` parameter to `CREATE_MODEL`, OML4SQL embeds the transformation definitions in the model and prepares the test and scoring data to match the build data.

The values for the `PREP_*` setting are described in the following table.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.PREP_AUTO_ON`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'ON'`.

### Note:

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-6 PREP\_\* Setting**

| Setting Name | Constant Value | String Value Equivalent | Description                                                                                          |
|--------------|----------------|-------------------------|------------------------------------------------------------------------------------------------------|
| PREP_AUTO    | PREP_AUTO_ON   | ON                      | This setting enables fully automated data preparation.<br>The default is <code>PREP_AUTO_ON</code> . |
|              | PREP_AUTO_OFF  | OFF                     | Disables fully automated data preparation.                                                           |

Table 48-6 (Cont.) PREP\_\* Setting

| Setting Name     | Constant Value          | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PREP_SCALE_2DNUM | PREP_SCALE_STDEV<br>EV  | PREP_SCALE_STDEV<br>EV  | This setting enables scaling data preparation for two-dimensional numeric columns. PREP_AUTO must be OFF for this setting to take effect.<br><br>PREP_SCALE_STDDEV: A request to divide the column values by the standard deviation of the column and is often provided together with PREP_SHIFT_MEAN to yield z-score normalization. |
|                  | PREP_SCALE_RANGE<br>E   | PREP_SCALE_RANGE<br>E   | A request to divide the column values by the range of values and is often provided together with PREP_SHIFT_MIN to yield a range of [0,1].                                                                                                                                                                                            |
| PREP_SCALE_NNUM  | PREP_SCALE_MAXABS<br>BS | PREP_SCALE_MAXABS<br>BS | This setting enables scaling data preparation for nested numeric columns. PREP_AUTO must be OFF for this setting to take effect. If specified, then the valid value for this setting is PREP_SCALE_MAXABS, which yields data in the range of [-1,1].                                                                                  |
| PREP_SHIFT_2DNUM | PREP_SHIFT_MEAN<br>M    | PREP_SHIFT_MEAN<br>M    | This setting enables centering data preparation for two-dimensional numeric columns. PREP_AUTO must be OFF for this setting to take effect.<br><br>PREP_SHIFT_MEAN: Results in subtracting the average of the column from each value.                                                                                                 |
|                  | PREP_SHIFT_MIN          | PREP_SHIFT_MIN          | Results in subtracting the minimum of the column from each value.                                                                                                                                                                                                                                                                     |

## 48.4.3 DBMS\_DATA\_MINING — Mining Function Settings

The settings described in this table apply to a mining function.

Table 48-7 Mining Function Settings

| Mining Function | Setting Name         | Setting Value                   | Description                                                 |
|-----------------|----------------------|---------------------------------|-------------------------------------------------------------|
| Association     | ASSO_MAX_RULE_LENGTH | TO_CHAR( 2<= numeric_expr <=20) | Maximum rule length for Association Rules.<br>Default is 4. |

Table 48-7 (Cont.) Mining Function Settings

| Mining Function | Setting Name            | Setting Value                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|-------------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Association     | ASSO_MIN_CONFIDENCE     | TO_CHAR( 0<=<br><i>numeric_expr</i><br><=1) | Minimum confidence for Association Rules.<br>Default is 0.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Association     | ASSO_MIN_SUPPORT        | TO_CHAR( 0<=<br><i>numeric_expr</i><br><=1) | Minimum support for Association Rules<br>Default is 0.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Association     | ASSO_MIN_SUPPORT_INT    | a positive<br>integer                       | Minimum absolute support that each rule must satisfy.<br>The value must be an integer.<br>Default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Association     | ASSO_MIN_REV_CONFIDENCE | TO_CHAR( 0<=<br><i>numeric_expr</i><br><=1) | Sets the Minimum Reverse Confidence that each rule<br>should satisfy.<br><br>The Reverse Confidence of a rule is defined as the<br>number of transactions in which the rule occurs<br>divided by the number of transactions in which the<br>consequent occurs.<br><br>The value is real number between 0 and 1.<br>The default is 0.                                                                                                                                                                                                   |
| Association     | ASSO_IN_RULES           | NULL                                        | Sets Including Rules applied for each association<br>rule: it specifies the list of items that at least one of<br>them must appear in each reported association rule,<br>either as antecedent or as consequent. It is a comma<br>separated string containing the list of including items.<br>If not set, the default behavior is, the filtering is not<br>applied.<br>For example,<br><br><pre>INSERT INTO sett_tab (setting_name,<br/>setting_value) VALUES<br/>      (dbms_data_mining.asso_in_rules,<br/>      ''a'', ''b'');</pre> |
| Association     | ASSO_EX_RULES           | NULL                                        | Sets Excluding Rules applied for each association<br>rule: it specifies the list of items that none of them can<br>appear in each reported Association Rules. It is a<br>comma separated string containing the list of<br>excluding items. No rule can contain any item in the<br>list.<br>The default is NULL.<br>For example,<br><br><pre>INSERT INTO sett_tab (setting_name,<br/>setting_value) VALUES<br/>      (dbms_data_mining.asso_ex_rules,<br/>      ''a'', ''b'');</pre>                                                    |

Table 48-7 (Cont.) Mining Function Settings

| Mining Function | Setting Name       | Setting Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|--------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Association     | ASSO_ANT_IN_RULES  | NULL          | <p>Sets Including Rules for the antecedent: it specifies the list of items that at least one of them must appear in the antecedent part of each reported association rule. It is a comma separated string containing the list of including items. The antecedent part of each rule must contain at least one item in the list.</p> <p>The default is NULL.</p> <p>For example,</p> <pre>INSERT INTO sett_tab (setting_name, setting_value) VALUES  (dbms_data_mining.asso_ant_in_rules, '''a','b''');</pre> |
| Association     | ASSO_ANT_EX_RULES  | NULL          | <p>Sets Excluding Rules for the antecedent: it specifies the list of items that none of them can appear in the antecedent part of each reported association rule. It is a comma separated string containing the list of excluding items. No rule can contain any item in the list in its antecedent part.</p> <p>The default is NULL.</p> <p>For example,</p> <pre>INSERT INTO sett_tab (setting_name, setting_value) VALUES  (dbms_data_mining.asso_ant_ex_rules, '''a','b''');</pre>                      |
| Association     | ASSO_CONS_IN_RULES | NULL          | <p>Sets Including Rules for the consequent: it specifies the list of items that at least one of them must appear in the consequent part of each reported association rule. It is a comma separated string containing the list of including items. The consequent of each rule must be an item in the list.</p> <p>The default is NULL.</p> <p>For example,</p> <pre>INSERT INTO sett_tab (setting_name, setting_value) VALUES  (dbms_data_mining.asso_cons_in_rules, '''a','b''');</pre>                    |

**Table 48-7 (Cont.) Mining Function Settings**

| Mining Function | Setting Name       | Setting Value                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|--------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Association     | ASSO_CONS_EX_RULES | NULL                                             | <p>Sets Excluding Rules for the consequent: it specifies the list of items that none of them can appear in the consequent part of each reported association rule. It is a comma separated string containing the list of excluding items. No rule can have any item in the list as its consequent.</p> <p>The excluding rule can be used to reduce the data that must be stored, but the user may be required to build extra model for executing different including or Excluding Rules.</p> <p>The default is NULL.</p> <p>For example,</p> <pre>INSERT INTO sett_tab (setting_name, setting_value) VALUES  (dbms_data_mining.asso_cons_ex_rules, '''a','b''');</pre>                                                                                                                                                   |
| Association     | ASSO_AGGREGATES    | NULL                                             | <p>Specifies the columns to be aggregated. It is a comma separated string containing the names of the columns for aggregation. Number of columns in the list must be &lt;= 10.</p> <p>You can set ASSO_AGGREGATES if ODMS_ITEM_ID_COLUMN_NAME is set indicating transactional input data. See <a href="#">DBMS_DATA_MINING - Global Settings</a>. The data table must have valid column names such as ITEM_ID and CASE_ID which are derived from ODMS_ITEM_ID_COLUMN_NAME and case_id_column_name respectively.</p> <p>ITEM_VALUE is not a mandatory value.</p> <p>The default is NULL.</p> <p>For each item, the user may supply several columns to aggregate. It requires more memory to buffer the extra data. Also, the performance impact can be seen because of the larger input data set and more operation.</p> |
| Association     | ASSO_ABS_ERROR     | 0.5 * MAX(ASSO_MIN_SUPPORT, ASSO_MIN_CONFIDENCE) | <p>Specifies the absolute error for the Association Rules sampling.</p> <p>A smaller value of ASSO_ABS_ERROR obtains a larger sample size which gives accurate results but takes longer computational time. "Set a reasonable value for ASSO_ABS_ERROR, such as its default value, to avoid large sample size. The default value is 0.5 * MAX(ASSO_MIN_SUPPORT, ASSO_MIN_CONFIDENCE).</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 48-7 (Cont.) Mining Function Settings**

| Mining Function | Setting Name            | Setting Value                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Association     | ASSO_CONF_LEVEL         | 0 ≤ ASSO_CONF_LEVEL ≤ 1                                                                                                              | <p>Specifies the confidence level for an Association Rules sample.</p> <p>A larger value of ASSO_CONF_LEVEL obtains a larger sample size. Any value between 0.9 and 1 is suitable. The default value is 0.95.</p>                                                                                                                                                                                                                                                                                                                               |
| Classification  | CLAS_COST_TABLE_NAME    | <i>table_name</i>                                                                                                                    | <p>(Decision Tree only) Name of a table that stores a cost matrix to be used by the algorithm in building the model. The cost matrix specifies the costs associated with misclassifications.</p> <p>Only Decision Tree models can use a cost matrix at build time. All classification algorithms can use a cost matrix at apply time.</p> <p>The cost matrix table is user-created. See <a href="#">"ADD_COST_MATRIX Procedure"</a> for the column requirements.</p> <p>See <i>Oracle Data Mining Concepts</i> for information about costs.</p> |
| Classification  | CLAS_PRIORS_TABLE_NAME  | <i>table_name</i>                                                                                                                    | <p>(Naive Bayes) Name of a table that stores prior probabilities to offset differences in distribution between the build data and the scoring data.</p> <p>The priors table is user-created. See <i>Oracle Data Mining User's Guide</i> for the column requirements. See <i>Oracle Data Mining Concepts</i> for additional information about priors.</p>                                                                                                                                                                                        |
| Classification  | CLAS_WEIGHTS_TABLE_NAME | <i>table_name</i>                                                                                                                    | <p>(GLM and SVM only) Name of a table that stores weighting information for individual target values in SVM classification and GLM logistic regression models. The weights are used by the algorithm to bias the model in favor of higher weighted classes.</p> <p>The class weights table is user-created. See <i>Oracle Data Mining User's Guide</i> for the column requirements. See <i>Oracle Data Mining Concepts</i> for additional information about class weights.</p>                                                                  |
| Classification  | CLAS_WEIGHTS_BALANCED   | ON<br>OFF                                                                                                                            | <p>This setting indicates that the algorithm must create a model that balances the target distribution. This setting is most relevant in the presence of rare targets, as balancing the distribution may enable better average accuracy (average of per-class accuracy) instead of overall accuracy (which favors the dominant class). The default value is OFF.</p>                                                                                                                                                                            |

Table 48-7 (Cont.) Mining Function Settings

| Mining Function    | Setting Name      | Setting Value                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clustering         | CLUS_NUM_CLUSTERS | <code>TO_CHAR( num<br/>eric_expr<br/>&gt;=1)</code> | <p>Maximum number of leaf clusters generated by a clustering algorithm. The algorithm may return fewer clusters, depending on the data.</p> <p>Enhanced <i>k</i>-Means usually produces the exact number of clusters specified by <code>CLUS_NUM_CLUSTERS</code>, unless there are fewer distinct data points.</p> <p>Expectation Maximization (EM) may return fewer clusters than the number specified by <code>CLUS_NUM_CLUSTERS</code> depending on the data. The number of clusters returned by EM cannot be greater than the number of components, which is governed by algorithm-specific settings. (See <i>Expectation Maximization Settings for Learning</i> table) Depending on these settings, there may be fewer clusters than components. If component clustering is disabled, the number of clusters equals the number of components.</p> <p>For EM, the default value of <code>CLUS_NUM_CLUSTERS</code> is system-determined. For <i>k</i>-Means and <i>O</i>-Cluster, the default is 10.</p> |
| Feature Extraction | FEAT_NUM_FEATURES | <code>TO_CHAR( num<br/>eric_expr<br/>&gt;=1)</code> | <p>Number of features to be extracted by a feature extraction model.</p> <p>The default is estimated from the data by the algorithm. If the matrix rank is smaller than this number, fewer features will be returned.</p> <p>For CUR Matrix Decomposition, the <code>FEAT_NUM_FEATURES</code> value is same as the <code>CURS_SVD_RANK</code> value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 48.4.4 DBMS\_DATA\_MINING — Global Settings

The configuration settings in this table are applicable to any type of model, but are currently only implemented for specific algorithms.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.ODMS_MISSING_VALUE_MEAN_MODE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'ODMS_MISSING_VALUE_MEAN_MODE'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

Table 48-8 Global Settings

| Setting Name                | Setting Value      | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ODMS_ITEM_ID_COLUMN_NAME    | <i>column_name</i> | <i>column_name</i>      | <p>(Association rules only) Name of a column that contains the items in a transaction. When this setting is specified, the algorithm expects the data to be presented in a native transactional format, consisting of two columns:</p> <ul style="list-style-type: none"> <li>• Case ID, either categorical or numeric</li> <li>• Item ID, either categorical or numeric</li> </ul> <p>A typical example of transactional data is market basket data, wherein a case represents a basket that may contain many items. Each item is stored in a separate row, and many rows may be needed to represent a case. The case ID values do not uniquely identify each row. Transactional data is also called multi-record case data.</p> <p>Association rules function is normally used with transactional data, but it can also be applied to single-record case data (similar to other algorithms).</p> <p>For more information about single-record and multi-record case data, see <i>Oracle SQL Developer Data Modeler User's Guide</i>.</p>                                                                                                                                                                              |
| ODMS_ITEM_VALUE_COLUMN_NAME | <i>column_name</i> | <i>column_name</i>      | <p>(Association rules only) Name of a column that contains a value associated with each item in a transaction. This setting is only used when a value has been specified for <code>ODMS_ITEM_ID_COLUMN_NAME</code> indicating that the data is presented in native transactional format.</p> <p>If <code>ASSO_AGGREGATES</code> is used, then the build data must include the following three columns and the columns specified in the <code>AGGREGATES</code> setting.</p> <ul style="list-style-type: none"> <li>• Case ID, either categorical or numeric</li> <li>• Item ID, either categorical or numeric, specified by <code>ODMS_ITEM_ID_COLUMN_NAME</code></li> <li>• Item value, either categorical or numeric, specified by <code>ODMS_ITEM_VALUE_COLUMN_NAME</code></li> </ul> <p>If <code>ASSO_AGGREGATES</code>, Case ID, and Item ID column are present, then the Item Value column may or may not appear.</p> <p>The Item Value column may specify information such as the number of items (for example, three apples) or the type of the item (for example, macintosh apples).</p> <p>For details on <code>ASSO_AGGREGATES</code>, see <a href="#">DBMS_DATA_MINING - Mining Function Settings</a>.</p> |

| Setting Name                 | Setting Value                                                          | String Value Equivalent                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ODMS_MISSING_VALUE_TREATMENT | ODMS_MISSING_VALUE_MEAN_MODE                                           | ODMS_MISSING_VALUE_MEAN_MODE                                           | <p>Indicates how to treat missing values in the training data. This setting does not affect the scoring data. The default value is ODMS_MISSING_VALUE_AUTO.</p> <p>ODMS_MISSING_VALUE_MEAN_MODE replaces missing values with the mean (numeric attributes) or the mode (categorical attributes) both at build time and apply time where appropriate.</p> <p>When ODMS_MISSING_VALUE_TREATMENT is set to ODMS_MISSING_VALUE_DELETE_ROW, the rows in the training data that contain missing values are deleted. However, if you want to replicate this missing value treatment in the scoring data, then you must perform the transformation explicitly.</p> |
|                              | ODMS_MISSING_VALUE_DELETE_ROW                                          | ODMS_MISSING_VALUE_DELETE_ROW                                          | The value ODMS_MISSING_VALUE_DELETE_ROW applies to all algorithms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                              | ODMS_MISSING_VALUE_AUTO                                                | ODMS_MISSING_VALUE_AUTO                                                | ODMS_MISSING_VALUE_AUTO performs different strategies for different algorithms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ODMS_ROW_WEIGHT_COLUMN_NAME  | column_name                                                            | column_name                                                            | <p>(GLM only) Name of a column in the training data that contains a weighting factor for the rows. The column data type must be NUMBER.</p> <p>Row weights can be used as a compact representation of repeated rows, as in the design of experiments where a specific configuration is repeated several times. Row weights can also be used to emphasize certain rows during model construction. For example, to bias the model towards rows that are more recent and away from potentially obsolete data.</p>                                                                                                                                             |
| ODMS_TEXT_POLICY_NAME        | The name of an Oracle Text POLICY created using CTX_DDL.CREATE_POLICY. | The name of an Oracle Text POLICY created using CTX_DDL.CREATE_POLICY. | <p>Affects how individual tokens are extracted from unstructured text.</p> <p>For details about CTX_DDL.CREATE_POLICY, see <i>Oracle Text Reference</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ODMS_TEXT_MAX_FEATURES       | 1 <= value                                                             | 1 <= value                                                             | The maximum number of distinct features, across all text attributes, to use from a document set passed to CREATE_MODEL. The default is 3000. ESA has the default value of 300000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ODMS_TEXT_MIN_DOCUMENTS      | Non-negative value                                                     | Non-negative value                                                     | <p>This is a text processing setting the controls how in how many documents a token needs to appear to be used as a feature.</p> <p>The default is 1. ESA has a default of 3.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Table 48-8 (Cont.) Global Settings

| Setting Name              | Setting Value                                  | String Value Equivalent                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ODMS_PARTITION_COLUMNS    | Comma separated list of data mining attributes | Comma separated list of data mining attributes | This setting indicates a request to build a partitioned model. The setting value is a comma-separated list of the data mining attributes to be used to determine the in-list partition key values. These data mining attributes are taken from the input columns unless an XFORM_LIST parameter is passed to CREATE_MODEL. If the XFORM_LIST parameter is passed to CREATE_MODEL, then the data mining attributes are taken from the attributes produced by these transformations. |
| ODMS_MAX_PARTITIONS       | 1 < value <= 1000000                           | 1 < value <= 1000000                           | This setting indicates the maximum number of partitions allowed for the model. The default is 1000.                                                                                                                                                                                                                                                                                                                                                                                |
| ODMS_SAMPLING             | ODMS_SAMPLING_ENABLE                           | ODMS_SAMPLING_ENABLE                           | This setting allows the user to request a sampling of the build data. The default is ODMS_SAMPLING_DISABLE.                                                                                                                                                                                                                                                                                                                                                                        |
|                           | ODMS_SAMPLING_DISABLE                          | ODMS_SAMPLING_DISABLE                          | Disables sampling of the build data.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ODMS_SAMPLE_SIZE          | 0 < Value                                      | 0 < Value                                      | This setting determines how many rows will be sampled (approximately). It can be set only if ODMS_SAMPLING is enabled. The default value is the system determined.                                                                                                                                                                                                                                                                                                                 |
| ODMS_PARTITION_BUILD_TYPE | ODMS_PARTITION_BUILD_INTRA                     | ODMS_PARTITION_BUILD_INTRA                     | This setting controls the parallel build of partitioned models.<br>ODMS_PARTITION_BUILD_INTRA — Each partition is built in parallel using all slaves.<br>The default mode is<br>ODMS_PARTITION_BUILD_HYBRID                                                                                                                                                                                                                                                                        |
|                           | ODMS_PARTITION_BUILD_INTER                     | ODMS_PARTITION_BUILD_INTER                     | Each partition is built entirely in a single slave, but multiple partitions may be built at the same time since multiple slaves are active.                                                                                                                                                                                                                                                                                                                                        |
|                           | ODMS_PARTITION_BUILD_HYBRID                    | ODMS_PARTITION_BUILD_HYBRID                    | It is a combination of the other two types and is recommended for most situations to adapt to dynamic environments.                                                                                                                                                                                                                                                                                                                                                                |
| ODMS_TABLESPACE_NAME      | <i>tablespace_name</i>                         | <i>tablespace_name</i>                         | This setting controls the storage specifications. If you explicitly sets this to the name of a tablespace (for which you have sufficient quota), then the specified tablespace storage creates the resulting model content. If you do not provide this setting, then the default tablespace of the user creates the resulting model content.                                                                                                                                       |
| ODMS_RANDOM_SEED          | Non-negative integer                           | Non-negative integer                           | The hash function with a random number seed generates a random number with uniform distribution. Users can control the random number seed by this setting. The default is 0.<br><br>This setting is used by Random Forest, Neural Network, and CUR Matrix Decomposition.                                                                                                                                                                                                           |

Table 48-8 (Cont.) Global Settings

| Setting Name | Setting Value | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ODMS_DETAILS | ODMS_ENABLE   | ODMS_ENABLE             | This setting reduces the space that is used while creating a model, especially a partitioned model. The default value is ODMS_ENABLE.<br><br>When the setting is ODMS_ENABLE, it creates model tables and views when the model is created. You can query the model with SQL.<br><br>The reduction in space depends on the model. Reduction on the order of 10x can be achieved. |
|              | ODMS_DISABLE  | ODMS_DISABLE            | When the setting is ODMS_DISABLE, model views are not created and tables relevant to model details are not created either.                                                                                                                                                                                                                                                      |

## 48.4.5 DBMS\_DATA\_MINING — Algorithm Settings: ALGO\_EXTENSIBLE\_LANG

The settings listed in the following table configure the behavior of the mining model with an Extensible algorithm. The mining model is built in R language.

The `RALG_*_FUNCTION` specifies the R script that is used to build, score, and view an R model and must be registered in the Oracle R Enterprise script repository. The R scripts are registered through Oracle R Enterprise with special privileges. When `ALGO_EXTENSIBLE_LANG` is set to R in the `MINING_MODEL_SETTING` table, the mining model is built in the R language. After the R model is built, the names of the R scripts are recorded in `MINING_MODEL_SETTING` table in the `SYS` schema. The scripts must exist in the script repository for the R model to function. The amount of R memory used to build, score, and view the R model through these R scripts can be controlled by Oracle R Enterprise.

All algorithm-independent `DBMS_DATA_MINING` subprograms can operate on an R model for mining functions such as Association, Attribute Importance, Classification, Clustering, Feature Extraction, and Regression.

The supported `DBMS_DATA_MINING` subprograms include, but are not limited, to the following:

- `ADD_COST_MATRIX` Procedure
- `COMPUTE_CONFUSION_MATRIX` Procedure
- `COMPUTE_LIFT` Procedure
- `COMPUTE_ROC` Procedure

- CREATE\_MODEL Procedure
- DROP\_MODEL Procedure
- EXPORT\_MODEL Procedure
- GET\_MODEL\_COST\_MATRIX Function
- IMPORT\_MODEL Procedure
- REMOVE\_COST\_MATRIX Procedure
- RENAME\_MODEL Procedure

**Table 48-9 ALGO\_EXTENSIBLE\_LANG Settings**

| Setting Name          | Setting Value                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RALG_BUILD_FUNCTION   | R_BUILD_FUNCTION_SCRIPT_NAME                           | Specifies the name of an existing registered R script for R algorithm mining model build function. The R script defines an R function for the first input argument for training data and returns an R model object. For Clustering and Feature Extraction mining function model build, the R attributes <code>dm\$nclus</code> and <code>dm\$nfeat</code> must be set on the R model to indicate the number of clusters and features respectively. The RALG_BUILD_FUNCTION must be set along with ALGO_EXTENSIBLE_LANG in the model_setting_table. |
| RALG_BUILD_PARAMETER  | SELECT <i>value</i><br>param_name, ... FROM DUAL       | Specifies a list of numeric and string scalar for optional input parameters of the model build function.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| RALG_SCORE_FUNCTION   | R_SCORE_FUNCTION_SCRIPT_NAME                           | Specifies the name of an existing registered R script to score data. The script returns a <code>data.frame</code> containing the corresponding prediction results. The setting is used to score data for mining functions such as Regression, Classification, Clustering, and Feature Extraction. This setting does not apply to Association and Attribute Importance functions                                                                                                                                                                    |
| RALG_WEIGHT_FUNCTION  | R_WEIGHT_FUNCTION_SCRIPT_NAME                          | Specifies the name of an existing registered R script for R algorithm that computes the weight (contribution) for each attribute in scoring. The script returns a <code>data.frame</code> containing the contributing weight for each attribute in a row. This function setting is needed for PREDICTION_DETAILS SQL function.                                                                                                                                                                                                                     |
| RALG_DETAILS_FUNCTION | R_DETAILS_FUNCTION_SCRIPT_NAME                         | Specifies the name of an existing registered R script for R algorithm that produces the model information. This setting is required to generate a model view.                                                                                                                                                                                                                                                                                                                                                                                      |
| RALG_DETAILS_FORMAT   | SELECT <i>type_value</i><br>column_name, ... FROM DUAL | Specifies the SELECT query for the list of numeric and string scalars for the output column type and the column name of the generated model view. This setting is required to generate a model view.                                                                                                                                                                                                                                                                                                                                               |

## 48.4.6 DBMS\_DATA\_MINING — Algorithm Settings: CUR Matrix Decomposition

The following settings configure the behavior of the CUR Matrix Decomposition algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.CURS_ROW_IMP_DISABLE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'CURS_ROW_IMP_DISABLE'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-10 CUR Matrix Decomposition Settings**

| Setting Name                      | Constant Value                       | String Value Equivalent              | Description                                                                                                                                                                                                           |
|-----------------------------------|--------------------------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CURS_APPROX_ATTR_NUM</code> | The value must be a positive integer | The value must be a positive integer | Defines the approximate number of attributes to be selected.<br>The default value is the number of attributes.                                                                                                        |
| <code>CURS_ROW_IMPORTANCE</code>  | <code>CURS_ROW_IMP_ENABLE</code>     | <code>CURS_ROW_IMP_ENABLE</code>     | Defines the flag indicating whether or not to perform row selection.<br>Enables row selection.<br>The default value is <code>CURS_ROW_IMP_DISABLE</code> .                                                            |
|                                   | <code>CURS_ROW_IMP_DISABLE</code>    | <code>CURS_ROW_IMP_DISABLE</code>    | Disables row selection.                                                                                                                                                                                               |
| <code>CURS_APPROX_ROW_NUM</code>  | The value must be a positive integer | The value must be a positive integer | Defines the approximate number of rows to be selected. This parameter is only used when users decide to perform row selection ( <code>CURS_ROW_IMP_ENABLE</code> ).<br>The default value is the total number of rows. |
| <code>CURS_SVD_RANK</code>        | The value must be a positive integer | The value must be a positive integer | Defines the rank parameter used in the column/row leverage score calculation.<br>If users do not provide an input value, the value is determined by the system.                                                       |

## 48.4.7 DBMS\_DATA\_MINING — Algorithm Settings: Decision Tree

These settings configure the behavior of the Decision Tree algorithm. Note that the Decision Tree settings are also used to configure the behavior of Random Forest as it constructs each individual Decision Tree.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.TREE_IMPURITY_ENTROPY`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'TREE_IMPURITY_ENTROPY'`.

### Note:

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-11 Decision Tree Settings**

| Setting Name           | Constant Value                                                                                                      | String Value Equivalent                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TREE_IMPURITY_METRIC   | TREE_IMPURITY_ENTROPY                                                                                               | TREE_IMPURITY_ENTROPY                                                                                                   | Tree impurity metric for Decision Tree.<br><br>Tree algorithms seek the best test question for splitting data at each node. The best splitter and split values are those that result in the largest increase in target value homogeneity (purity) for the entities in the node. Purity is by a metric. By default, the algorithm uses TREE_IMPURITY_GINI. |
|                        | TREE_IMPURITY_GINI                                                                                                  | TREE_IMPURITY_GINI                                                                                                      | Decision trees can use either Gini (TREE_IMPURITY_GINI) or entropy (TREE_IMPURITY_ENTROPY) as the purity metric.                                                                                                                                                                                                                                          |
| TREE_TERM_MAX_DEPTH    | For Decision Tree:<br>$2 \leq a \text{ number} \leq 20$<br>For Random Forest:<br>$2 \leq a \text{ number} \leq 100$ | For Decision Tree:<br>$2 \leq a \text{ number} \leq 20$<br><br>For Random Forest:<br>$2 \leq a \text{ number} \leq 100$ | Criteria for splits: maximum tree depth (the maximum number of nodes between the root and any leaf node, including the leaf node).<br>For Decision Tree, the default is 7.<br>For Random Forest, the default is 16.                                                                                                                                       |

## 48.4.8 DBMS\_DATA\_MINING — Algorithm Settings: Expectation Maximization

These algorithm settings configure the behavior of the Expectation Maximization algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.EMCS_ATTR_FILTER_ENABLE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'EMCS_ATTR_FILTER_ENABLE'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-12 Expectation Maximization Settings for Data Preparation and Analysis**

| Setting Name            | Constant Value                  | String Value Equivalent         | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMCS_ATTRIBUTE_FILTER   | EMCS_ATTR_FILTER_ENABLE         | EMCS_ATTR_FILTER_ENABLE         | Whether or not to include uncorrelated attributes in the model. When EMCS_ATTRIBUTE_FILTER is enabled, uncorrelated attributes are not included.                                                                                                                                                                                                                                                |
|                         |                                 |                                 | Default is system-determined.                                                                                                                                                                                                                                                                                                                                                                   |
|                         | EMCS_ATTR_FILTER_DISABLE        | EMCS_ATTR_FILTER_DISABLE        | Includes uncorrelated attributes in the model.                                                                                                                                                                                                                                                                                                                                                  |
| EMCS_MAX_NUM_ATTR_2D    | TO_CHAR( numeric_expr >=1)      | TO_CHAR( numeric_expr >=1)      | Maximum number of correlated attributes to include in the model.<br>Note: This setting applies only to attributes that are not nested (2D).<br>Default is 50.                                                                                                                                                                                                                                   |
| EMCS_NUM_DISTRIBUTION   | EMCS_NUM_DISTR_BERNOULLI        | EMCS_NUM_DISTR_BERNOULLI        | The distribution for modeling numeric attributes. Applies to the input table or view as a whole and does not allow per-attribute specifications.<br>The options include Bernoulli, Gaussian, or system-determined distribution. When Bernoulli or Gaussian distribution is chosen, all numeric attributes are modeled using the same type of distribution.<br>Default is EMCS_NUM_DISTR_SYSTEM. |
|                         | EMCS_NUM_DISTR_GAUSSIAN         | EMCS_NUM_DISTR_GAUSSIAN         | Models all numeric attributes using Gaussian distribution.                                                                                                                                                                                                                                                                                                                                      |
|                         | EMCS_NUM_DISTR_SYSTEM           | EMCS_NUM_DISTR_SYSTEM           | When the distribution is system-determined, individual attributes may use different distributions (either Bernoulli or Gaussian), depending on the data.                                                                                                                                                                                                                                        |
| EMCS_NUM_EQUIWIDTH_BINS | TO_CHAR( 1 <numeric_expr <=255) | TO_CHAR( 1 <numeric_expr <=255) | Number of equi-width bins that will be used for gathering cluster statistics for numeric columns.<br>Default is 11.                                                                                                                                                                                                                                                                             |
| EMCS_NUM_PROJECTIONS    | TO_CHAR( numeric_expr >=1)      | TO_CHAR( numeric_expr >=1)      | Specifies the number of projections that will be used for each nested column. If a column has fewer distinct attributes than the specified number of projections, the data will not be projected. The setting applies to all nested columns.<br>Default is 50.                                                                                                                                  |
| EMCS_NUM_QUANTILE_BINS  | TO_CHAR( 1 <numeric_expr <=255) | TO_CHAR( 1 <numeric_expr <=255) | Specifies the number of quantile bins that will be used for modeling numeric columns with multivalued Bernoulli distributions.<br>Default is system-determined.                                                                                                                                                                                                                                 |

**Note:**

This setting applies only to attributes that are not nested.

**Table 48-12 (Cont.) Expectation Maximization Settings for Data Preparation and Analysis**

| Setting Name       | Constant Value                     | String Value Equivalent                | Description                                                                                                                                                          |
|--------------------|------------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMCS_NUM_TOPN_BINS | TO_CHAR( 1<br><numeric_expr <=255) | TO_CHAR( 1<br><numeric_ex<br>pr <=255) | Specifies the number of top-N bins that will be used for modeling categorical columns with multivalued Bernoulli distributions.<br><br>Default is system-determined. |

**Table 48-13 Expectation Maximization Settings for Learning**

| Setting Name               | Constant Value                           | String Value Equivalent                  | Description                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|------------------------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMCS_CONVERGENCE_CRITERION | EMCS_CONV_CRIT_HEL<br>DASIDE             | EMCS_CONV_CRIT_HEL<br>DASIDE             | The convergence criterion for EM. The convergence criterion may be based on a held-aside data set, or it may be Bayesian Information Criterion.<br><br>EMCS_CONV_CRIT_HELDA<br>SIDE: Uses a held-aside data set for convergence criterion.<br><br>Default is system determined.                                                                                 |
|                            | EMCS_CONV_CRIT_BIC                       | EMCS_CONV_CRIT_BIC                       | Uses the Bayesian Information Criterion (BIC) for convergence.                                                                                                                                                                                                                                                                                                  |
| EMCS_LOGLIKE_IMPROVEMENT   | TO_CHAR( 0 <<br>numeric_expr < 1)        | TO_CHAR( 0 <<br>numeric_expr < 1)        | When the convergence criterion is based on a held-aside data set (EMCS_CONVERGENCE_CRITERION = EMCS_CONV_CRIT_HELDA<br>SIDE), this setting specifies the percentage improvement in the value of the log likelihood function that is required for adding a new component to the model.<br><br>Default value is 0.001.                                            |
| EMCS_NUM_COMPONENTS        | TO_CHAR(numeric_ex<br>pr >=1)            | TO_CHAR(numeric_ex<br>pr >=1)            | Maximum number of components in the model. If model search is enabled, the algorithm automatically determines the number of components based on improvements in the likelihood function or based on regularization, up to the specified maximum.<br><br>The number of components must be greater than or equal to the number of clusters.<br><br>Default is 20. |
| EMCS_NUM_ITERATIONS        | TO_CHAR(numeric_ex<br>pr >=1)            | TO_CHAR(numeric_ex<br>pr >=1)            | Specifies the maximum number of iterations in the EM algorithm.<br><br>Default is 100.                                                                                                                                                                                                                                                                          |
| EMCS_MODEL_SEARCH          | EMCS_MODEL_SEARCH_<br>ENABLE             | EMCS_MODEL_SEARCH_<br>ENABLE             | This setting enables model search in EM where different model sizes are explored and a best size is selected.<br><br>The default is EMCS_MODEL_SEARCH_DISABLE.                                                                                                                                                                                                  |
|                            | EMCS_MODEL_SEARCH_<br>DISABLE (default). | EMCS_MODEL_SEARCH_<br>DISABLE (default). | Deactivates model search.                                                                                                                                                                                                                                                                                                                                       |

**Table 48-13 (Cont.) Expectation Maximization Settings for Learning**

| Setting Name           | Constant Value                     | String Value Equivalent            | Description                                                                                                                     |
|------------------------|------------------------------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| EMCS_REMOVE_COMPONENTS | EMCS_REMOVE_COMPS_ENABLE (default) | EMCS_REMOVE_COMPS_ENABLE (default) | This setting allows the EM algorithm to remove a small component from the solution.<br>The default is EMCS_REMOVE_COMPS_ENABLE. |
|                        | EMCS_REMOVE_COMPS_DISABLE          | EMCS_REMOVE_COMPS_DISABLE          | Prevents the EM algorithm from removing small components.                                                                       |
| EMCS_RANDOM_SEED       | Non-negative integer               | Non-negative integer               | This setting controls the seed of the random generator used in EM. The default is 0.                                            |

**Table 48-14 Expectation Maximization Settings for Component Clustering**

| Setting Name            | Constant Value             | String Value Equivalent    | Description                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|----------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMCS_CLUSTER_COMPONENTS | EMCS_CLUSTER_COMP_ENABLE   | EMCS_CLUSTER_COMP_ENABLE   | Enables or disables the grouping of EM components into high-level clusters. When disabled, the components themselves are treated as clusters.<br>When component clustering is enabled, model scoring through the SQL CLUSTER function will produce assignments to the higher level clusters.<br>Default is EMCS_CLUSTER_COMP_ENABLE.                |
|                         | EMCS_CLUSTER_COMP_DISABLE  | EMCS_CLUSTER_COMP_DISABLE  | When clustering is disabled, the CLUSTER function will produce assignments to the original components.                                                                                                                                                                                                                                              |
| EMCS_CLUSTER_THRESHOLD  | TO_CHAR( numeric_expr >=1) | TO_CHAR( numeric_expr >=1) | Dissimilarity threshold that controls the clustering of EM components. When the dissimilarity measure is less than the threshold, the components are combined into a single cluster.<br>A lower threshold may produce more clusters that are more compact. A higher threshold may produce fewer clusters that are more spread out.<br>Default is 2. |
| EMCS_LINKAGE_FUNCTION   | EMCS_LINKAGE_SINGLE        | EMCS_LINKAGE_SINGLE        | Allows the specification of a linkage function for the agglomerative clustering step.<br>EMCS_LINKAGE_SINGLE uses the nearest distance within the branch. The clusters tend to be larger and have arbitrary shapes.<br>Default is EMCS_LINKAGE_SINGLE.                                                                                              |
|                         | EMCS_LINKAGE_AVERAGE       | EMCS_LINKAGE_AVERAGE       | EMCS_LINKAGE_AVERAGE uses the average distance within the branch. There is less chaining effect and the clusters are more compact.                                                                                                                                                                                                                  |
|                         | EMCS_LINKAGE_COMPLETE      | EMCS_LINKAGE_COMPLETE      | EMCS_LINKAGE_COMPLETE uses the maximum distance within the branch. The clusters are smaller and require strong component overlap.                                                                                                                                                                                                                   |

**Table 48-15** Expectation Maximization Settings for Cluster Statistics

| Setting Name              | Constant Value                 | String Value Equivalents       | Description                                                                                                                                                                                                        |
|---------------------------|--------------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMCS_CLUSTER_STATISTICS   | EMCS_CLUS_STATS_ENABLE         | EMCS_CLUS_STATS_ENABLE         | Enables or disables the gathering of descriptive statistics for clusters (centroids, histograms, and rules).<br>Default is EMCS_CLUS_STATS_ENABLE.                                                                 |
|                           | EMCS_CLUS_STATS_DISABLE        | EMCS_CLUS_STATS_DISABLE        | When statistics are disabled, model size is reduced, and GET_MODEL_DETAILS_EM only returns taxonomy (hierarchy) and cluster counts.                                                                                |
| EMCS_MIN_PCT_ATTR_SUPPORT | TO_CHAR( 0 < numeric_expr < 1) | TO_CHAR( 0 < numeric_expr < 1) | Minimum support required for including an attribute in the cluster rule. The support is the percentage of the data rows assigned to a cluster that must have non-null values for the attribute.<br>Default is 0.1. |

## 48.4.9 DBMS\_DATA\_MINING — Algorithm Settings: Explicit Semantic Analysis

Explicit Semantic Analysis (ESA) is a useful technique for extracting meaningful and interpretable features.

The settings listed in the following table configure the ESA values.

**Table 48-16** Explicit Semantic Analysis Settings

| Setting Name         | Constant Value                        | String Value Equivalent               | Description                                                                                                                                                         |
|----------------------|---------------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ESAS_VALUE_THRESHOLD | Non-negative number                   | Non-negative number                   | This setting thresholds a small value for attribute weights in the transformed build data. The default is 1e-8.                                                     |
| ESAS_MIN_ITEMS       | Text input 100<br>Non-text input is 0 | Text input 100<br>Non-text input is 0 | This setting determines the minimum number of non-zero entries that need to be present in an input row. The default is 100 for text input and 0 for non-text input. |
| ESAS_TOPN_FEATURES   | A positive integer                    | A positive integer                    | This setting controls the maximum number of features per attribute. The default is 1000.                                                                            |

### See Also:

*Oracle Data Mining Concepts* for information about ESA.

## 48.4.10 DBMS\_DATA\_MINING — Algorithm Settings: Exponential Smoothing

These settings configure the behavior of the Exponential Smoothing (ESM) algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.EXSM_SIMPLE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'EXSM_SIMPLE'`.

### Note:

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

The settings listed in the following table configure Exponential Smoothing values.

**Table 48-17 Exponential Smoothing Settings**

| Setting Name | Constant Value   | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXSM_MODEL   | EXSM_SIMPLE      | EXSM_SIMPLE             | This setting specifies the model.<br><br>EXSM_SIMPLE: Forecasts data as a weighted moving average, with the influence of past observations declining exponentially with the length of time since the observation occurred. Errors in estimation are assumed to be normally distributed, with constant mean and variance. It is appropriate for data with no clear trend or seasonal pattern.<br><br>The default value is EXSM_SIMPLE. |
|              | EXSM_SIMPLE_MULT | EXSM_SIMPLE_MULT_ERR    | Forecasts data as a weighted moving average, with the influence of past observations declining exponentially with the length of time since the observation occurred. Errors in estimation are assumed to be proportional to the level of the prior estimate.                                                                                                                                                                          |
|              | EXSM_HOLT        | EXSM_HOLT               | Applies Holt's linear exponential smoothing method, designed to forecast data with an underlying linear trend.                                                                                                                                                                                                                                                                                                                        |
|              | EXSM_HOLT_DMP    | EXSM_HOLT_DAMPED        | Applies Holt's linear exponential smoothing with a damping factor to progressively reduce the strength of the trend over time.                                                                                                                                                                                                                                                                                                        |
|              | EXSM_MULT_TRND   | EXSM_MULT_TREND         | Applies an exponential smoothing framework with a multiplicative trend component, effectively capturing data where trends are not linear but grow or decay over time.                                                                                                                                                                                                                                                                 |

**Table 48-17 (Cont.) Exponential Smoothing Settings**

| Setting Name | Constant Value  | String Value Equivalent     | Description                                                                                                                                                                                                         |
|--------------|-----------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | EXSM_MULTRD_DMP | EXSM_MULT_TREND_DAMPED      | Applies an exponential smoothing algorithm with a multiplicative trend that diminishes over time, providing a conservative approach to trend estimation.                                                            |
|              | EXSM_SEAS_ADD   | EXSM_SEASON_ADD             | Applies an exponential smoothing with an additive seasonal component, isolating and accounting for seasonal variations without incorporating a trend.                                                               |
|              | EXSM_SEAS_MUL   | EXSM_SEASON_MUL             | Executes exponential smoothing with a multiplicative seasonal component, capturing seasonal effects that increase or decrease in proportion to the level of the series.                                             |
|              | EXSM_HW         | EXSM_WINTERS                | Applies the Holt-Winters method with additive trends and multiplicative seasonality, offering a robust model for data with both linear trend and proportional seasonal variation.                                   |
|              | EXSM_HW_DMP     | EXSM_WINTERS_DAMPED         | Applies the Holt-Winters method with a damped trend and multiplicative seasonality, moderating the linear trend over time while still capturing proportional seasonal changes.                                      |
|              | EXSM_HW_ADDSEA  | EXSM_ADDWINTERS             | Applies the Holt-Winters additive model to simultaneously smooth data with linear trends and additive seasonal effects.                                                                                             |
|              | EXSM_DHW_ADDSEA | EXSM_ADDWINTERS_DAMPED      | Applies the Holt-Winters additive approach with a damping mechanism, reducing the impact of the trend and seasonal components over time.                                                                            |
|              | EXSM_HWMT       | EXSM_WINTERS_MULT_TREND     | Applies the Holt-Winters model with both trend and seasonality components being multiplicative, suited for series where the seasonal variations and trends are both increasing or decreasing proportional to level. |
|              | EXSM_HWMT_DMP   | EXSM_WINTERS_MULT_TREND_DMP | Applies the Holt-Winters model with a damped multiplicative trend, effectively moderating the exponential increase or decrease of both trend and seasonal components over time.                                     |

Table 48-17 (Cont.) Exponential Smoothing Settings

| Setting Name     | Constant Value        | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXSM_SEASONALITY | positive integer > 1  | positive integer > 1    | <p>This setting specifies a positive integer value as the length of seasonal cycle.</p> <p>The value it takes must be larger than 1. For example, setting value 4 means that every group of four observations forms a seasonal cycle.</p> <p>This setting is only applicable and must be provided for models with seasonality, otherwise the model throws an error.</p> <p>When EXSM_INTERVAL is not set, this setting applies to the original input time series. When EXSM_INTERVAL is set, this setting applies to the accumulated time series.</p> |
| EXSM_INTERVAL    | EXSM_INTERVAL_YEAR    | EXSM_INTERVAL_YEAR      | <p>This setting only applies and must be provided when the time column (case_id column) has datetime type. It specifies the spacing interval of the accumulated equally spaced time series.</p> <p>The model throws an error if the time column of input table is of datetime type and setting EXSM_INTERVAL is not provided.</p> <p>EXSM_INTERVAL_YEAR: This option sets the spacing interval of the accumulated time series to one year. When selected, the data is aggregated or summarized on a yearly basis.</p>                                 |
|                  | EXSM_INTERVAL_QUARTER | EXSM_INTERVAL_QUARTER   | <p>This option sets the spacing interval to a quarter, aggregating the data for every three months.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                  | EXSM_INTERVAL_MONTH   | EXSM_INTERVAL_MONTH     | <p>This option adjusts the spacing interval to one month. The accumulated time series represent aggregated or summarized data for each month.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
|                  | EXSM_INTERVAL_WEEK    | EXSM_INTERVAL_WEEK      | <p>With this option data is aggregated or summarized on a weekly basis, setting the spacing interval to one week.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                  | EXSM_INTERVAL_DAY     | EXSM_INTERVAL_DAY       | <p>This option adjusts the spacing interval to one day. It's suitable for scenarios where daily aggregated insights are required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                  | EXSM_INTERVAL_HOUR    | EXSM_INTERVAL_HOUR      | <p>For more granular insights, this option sets the spacing interval to one hour. It's especially useful when analyzing data that changes significantly within a day.</p>                                                                                                                                                                                                                                                                                                                                                                             |
|                  | EXSM_INTERVAL_MINUTE  | EXSM_INTERVAL_MINUTE    | <p>With this option the spacing is set to one minute. This provides a very detailed view of data, suitable for applications like high-frequency trading or real-time monitoring systems.</p>                                                                                                                                                                                                                                                                                                                                                          |

**Table 48-17 (Cont.) Exponential Smoothing Settings**

| Setting Name             | Constant Value                   | String Value Equivalent          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | EXSM_INTERVAL_S<br>EC            | EXSM_INTERVAL_S<br>ECOND         | For most granular details, this options sets the spacing interval to one second. It's tailored for scenarios requiring real-time or near-real-time analysis.                                                                                                                                                                                                                                                                                                                                   |
| EXSM_INITVL_OPT<br>IMIZE | EXSM_INITVL_OPT<br>IMIZE_ENABLE  | EXSM_INITVL_OPT<br>IMIZE_ENABLE  | The setting <code>EXSM_INITVL_OPTIMIZE</code> determines whether initial values are optimized during model build.<br><br>The default value is <code>EXSM_INITVL_OPTIMIZE_ENABLE</code> .                                                                                                                                                                                                                                                                                                       |
|                          | EXSM_INITVL_OPT<br>IMIZE_DISABLE | EXSM_INITVL_OPT<br>IMIZE_DISABLE | <b>Note:</b><br><code>EXSM_INITVL_OPTIMIZE</code> can only be set to <code>EXSM_INITVL_OPTIMIZE_DISABLE</code> if the user has set <code>EXSM_MODEL</code> to <code>EXSM_HW</code> or <code>EXSM_HW_ADDSEA</code> . If <code>EXSM_MODEL</code> is set to another model type or is not specified, you get an error 40213 (conflicting settings) and the model is not built.                                                                                                                     |
| EXSM_ACCUMULATE          | EXSM_ACCU_TOTAL                  | EXSM_ACCU_TOTAL                  | This setting only applies and must be provided when the time column has datetime type. It specifies how to generate the value of the accumulated time series from the input time series.<br><br><code>EXSM_ACCU_TOTAL</code> : This option calculates the total sum of the time series values within a specified interval. When selected, it will aggregate the data by summing up all the individual values in the datetime range.<br><br>The default value is <code>EXSM_ACCU_TOTAL</code> . |
|                          | EXSM_ACCU_STD                    | EXSM_ACCU_STD                    | This option computes the standard deviation of the time series values within a specified interval. It helps you understand the amount of variation or dispersion in your data.                                                                                                                                                                                                                                                                                                                 |
|                          | EXSM_ACCU_MAX                    | EXSM_ACCU_MAX                    | By selecting this option, the maximum value of the time series within a specified interval will be determined. It helps in identifying the peak value in the given range.                                                                                                                                                                                                                                                                                                                      |
|                          | EXSM_ACCU_MIN                    | EXSM_ACCU_MIN                    | This option focuses on determining the minimum value of the time series within a specified interval. It is useful for identifying the lowest value in the time series for the given datetime range.                                                                                                                                                                                                                                                                                            |
|                          | EXSM_ACCU_AVG                    | EXSM_ACCU_AVG                    | This specifies the average value of your time series within a specified interval. It calculates the mean value of all data points in the specified range.                                                                                                                                                                                                                                                                                                                                      |

Table 48-17 (Cont.) Exponential Smoothing Settings

| Setting Name    | Constant Value                      | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                          |
|-----------------|-------------------------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXSM_SETMISSING | EXSM_ACCU_MEDIA<br>N                | EXSM_ACCU_MEDIA<br>N    | This option provides the median of the time series values within the given interval. The median gives a central value, which can be especially useful if your data contains outliers.                                                                                                                                                                |
|                 | EXSM_ACCU_COUNT                     | EXSM_ACCU_COUNT         | This option counts the number of time series values within the specified interval. It is helpful if you want to know how many data points are present in a certain datetime range.                                                                                                                                                                   |
|                 | Specify an option:<br>EXSM_MISS_MIN | EXSM_MISS_MIN           | This setting specifies how to handle missing values, which may come from input data and/or the accumulation process of time series. You can specify either a number or an option. If a number is specified, all the missing values are set to that number.<br><br>EXSM_MISS_MIN: Replaces missing value with minimum of the accumulated time series. |
|                 | EXSM_MISS_MAX                       | EXSM_MISS_MAX           | Replaces missing value with maximum of the accumulated time series.                                                                                                                                                                                                                                                                                  |
|                 | EXSM_MISS_AVG                       | EXSM_MISS_AVG           | Replaces missing value with average of the accumulated time series.                                                                                                                                                                                                                                                                                  |
|                 | EXSM_MISS_MEDIA<br>N                | EXSM_MISS_MEDIA<br>N    | Replaces missing value with median of the accumulated time series.                                                                                                                                                                                                                                                                                   |
|                 | EXSM_MISS_LAST                      | EXSM_MISS_LAST          | Replaces missing value with last non-missing value of the accumulated time series.                                                                                                                                                                                                                                                                   |
|                 | EXSM_MISS_FIRST                     | EXSM_MISS_FIRST         | Replaces missing value with first non-missing value of the accumulated time series.                                                                                                                                                                                                                                                                  |
|                 | EXSM_MISS_PREV                      | EXSM_MISS_PREV          | Replaces missing value with the previous non-missing value of the accumulated time series.                                                                                                                                                                                                                                                           |
|                 | EXSM_MISS_NEXT                      | EXSM_MISS_NEXT          | Replaces missing value with the next non-missing value of the accumulated time series.                                                                                                                                                                                                                                                               |
|                 | EXSM_MISS_AUTO                      | EXSM_MISS_AUTO          | EXSM model treats the input data as an irregular (non-uniformly spaced) time series.<br><br>If this setting is not provided, EXSM_MISS_AUTO is the default value. In such a case, the model treats the input time series as irregular time series, viewing missing values as gaps.                                                                   |

Table 48-17 (Cont.) Exponential Smoothing Settings

| Setting Name          | Constant Value                                  | String Value Equivalent                         | Description                                                                                                                                                                                                                                                                                                                                |
|-----------------------|-------------------------------------------------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXSM_PREDICTION_STEP  | It must be set to a number between 1-30.        | It must be set to a number between 1-30.        | This setting specifies how many steps ahead the predictions are to be made. If it is not set, the default value is 1: the model gives one-step-ahead prediction. A value greater than 30 results in an error.                                                                                                                              |
| EXSM_CONFIDENCE_LEVEL | It must be a number between 0 and 1, exclusive. | It must be a number between 0 and 1, exclusive. | This setting specifies the desired confidence level for prediction. The lower and upper bounds of the specified confidence interval is reported. If this setting is not specified, the default confidence level is 95%.                                                                                                                    |
| EXSM_OPT_CRITERION    | EXSM_OPT_CRIT_LIK<br>IK                         | EXSM_OPT_CRIT_LIK<br>IK                         | This setting specifies the desired optimization criterion. The optimization criterion is useful as a diagnostic for comparing models' fit to the same data.<br><br>EXSM_OPT_CRIT_LIK: This represents the negative double of the logarithm of the likelihood associated with a given model.<br><br>The default value is EXSM_OPT_CRIT_LIK. |
|                       | EXSM_OPT_CRIT_MSE                               | EXSM_OPT_CRIT_MSE                               | This provides the mean squared error pertaining to the model.                                                                                                                                                                                                                                                                              |
|                       | EXSM_OPT_CRIT_A                                 | EXSM_OPT_CRIT_A                                 | This denotes the average of the mean squared error over a time window as specified by the user.                                                                                                                                                                                                                                            |
|                       | EXSM_OPT_CRIT_SIG                               | EXSM_OPT_CRIT_SIG                               | This metric captures the standard deviation of the residuals of the model.                                                                                                                                                                                                                                                                 |
|                       | EXSM_OPT_CRIT_MAE                               | EXSM_OPT_CRIT_MAE                               | This metric conveys the average absolute error associated with the model. It measures the size of the error.                                                                                                                                                                                                                               |
| EXSM_NMSE             | positive integer                                | positive integer                                | This setting specifies the length of the window used in computing the error metric Average Mean Square Error (AMSE).                                                                                                                                                                                                                       |

## 48.4.11 DBMS\_DATA\_MINING — Algorithm Settings: Generalized Linear Model

The settings listed in the following table configure the behavior of the Generalized Linear Model algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.GLMS_FTR_GEN_QUADRATIC`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'GLMS_FTR_GEN_QUADRATIC'`.

### Note:

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-18 DBMS\_DATA\_MINING GLM Settings**

| Setting Name           | Constant Value                                   | String Value Equivalent                          | Description                                                                                                                                                                                                                                                                               |
|------------------------|--------------------------------------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GLMS_CONF_LEVEL        | <code>TO_CHAR(0 &lt; numeric_expr &lt; 1)</code> | <code>TO_CHAR(0 &lt; numeric_expr &lt; 1)</code> | The confidence level for coefficient confidence intervals.<br>The default confidence level is 0.95.                                                                                                                                                                                       |
| GLMS_FTR_GEN_METHOD    | <code>GLMS_FTR_GEN_QUADRATIC</code>              | <code>GLMS_FTR_GEN_QUADRATIC</code>              | Whether feature generation is quadratic or cubic. When feature generation is enabled, the algorithm automatically chooses the most appropriate feature generation method based on the data.<br><br><code>GLMS_FTR_GEN_QUADRATIC</code> : Generates features using a quadratic method.     |
|                        | <code>GLMS_FTR_GEN_CUBIC</code>                  | <code>GLMS_FTR_GEN_CUBIC</code>                  | Generates features using a cubic method.                                                                                                                                                                                                                                                  |

**Table 48-18 (Cont.) DBMS\_DATA\_MINING GLM Settings**

| Setting Name              | Constant Value                           | String Value Equivalent                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GLMS_FTR_SELECTION        | GLMS_FTR_SEL_ALPHA_INV                   | GLMS_FTR_SEL_ALPHA_INV                   | Uses Alpha Inverse Criterion for feature selection.                                                                                                                                                                                                                                                                                                                                                                                                         |
|                           | GLMS_FTR_SELECTION_ENABLE                | GLMS_FTR_SELECTION_ENABLE                | Whether or not feature selection is enabled for GLM.<br>By default, feature selection is not enabled.                                                                                                                                                                                                                                                                                                                                                       |
|                           | GLMS_FTR_SELECTION_DISABLE               | GLMS_FTR_SELECTION_DISABLE               | Disables feature selection.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| GLMS_MAX_FEATURES         | TO_CHAR(0 < <i>numeric_expr</i> <= 2000) | TO_CHAR(0 < <i>numeric_expr</i> <= 2000) | When feature selection is enabled, this setting specifies the maximum number of features that can be selected for the final model.<br>By default, the algorithm limits the number of features to ensure sufficient memory.                                                                                                                                                                                                                                  |
| GLMS_PRUNE_MODEL          | GLMS_PRUNE_MODEL_ENABLE                  | GLMS_PRUNE_MODEL_ENABLE                  | Enables or disables pruning of features in the final model. Pruning is based on T-Test statistics for linear regression, or Wald Test statistics for logistic regression. Features are pruned in a loop until all features are statistically significant with respect to the full data.<br>When feature selection is enabled, the algorithm automatically prunes as per the description.<br>When feature selection is disabled, you cannot specify pruning. |
|                           | GLMS_PRUNE_MODEL_DISABLE                 | GLMS_PRUNE_MODEL_DISABLE                 | Disables pruning of features.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| GLMS_REFERENCE_CLASS_NAME | <i>target_value</i>                      | <i>target_value</i>                      | The target value used as the reference class in a binary logistic regression model. Probabilities are produced for the other class.<br>By default, the algorithm chooses the value with the highest prevalence (the most cases) for the reference class.                                                                                                                                                                                                    |
| GLMS_RIDGE_REGRESSION     | GLMS_RIDGE_REG_ENABLE                    | GLMS_RIDGE_REG_ENABLE                    | Enable or disable ridge regression. Ridge applies to both regression and classification data mining techniques.<br>When ridge is enabled, prediction bounds are not produced by the PREDICTION_BOUNDS SQL function.<br><b>Note:</b> Ridge may only be enabled when feature selection is not specified, or has been explicitly disabled. If ridge regression is enabled, you cannot enable feature selection and an exception is raised.                     |
|                           | GLMS_RIDGE_REG_DISABLE                   | GLMS_RIDGE_REG_DISABLE                   | Disables ridge regression.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 48-18 (Cont.) DBMS\_DATA\_MINING GLM Settings

| Setting Name         | Constant Value                                  | String Value Equivalent                         | Description                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GLMS_RIDGE_VALUE     | TO_CHAR<br>(numeric_expr > 0)                   | TO_CHAR<br>(numeric_expr > 0)                   | The value of the ridge parameter. This setting is only used when the algorithm is configured to use ridge regression.<br><br>If ridge regression is enabled internally by the algorithm, then the ridge parameter is determined by the algorithm.                                                                           |

## 48.4.12 DBMS\_DATA\_MINING — Algorithm Settings: k-Means

The settings listed in the following table configure the behavior of the *k*-Means algorithm.

/

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.KMNS_COSINE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'KMNS_COSINE'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-19 k-Means Settings**

| Setting Name              | Constant Value                 | String Value Equivalent        | Description                                                                                                                                                                                                                                                                                                                                                                                      |

## 48.4.13 DBMS\_DATA\_MINING — Algorithm Settings: Naive Bayes

The settings listed in the following table configure the behavior of the Naive Bayes algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.NABS_PAIRWISE_THRESHOLD`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'NABS_PAIRWISE_THRESHOLD'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-20 Naive Bayes Settings**

| Setting Name             | Setting Value                                      | String Value Equivalent                            | Description                                                          |
|--------------------------|----------------------------------------------------|----------------------------------------------------|----------------------------------------------------------------------|
| NABS_PAIRWISE_THRESHOLD  | <code>TO_CHAR(0 &lt;= numeric_expr &lt;= 1)</code> | <code>TO_CHAR(0 &lt;= numeric_expr &lt;= 1)</code> | Value of pairwise threshold for NB algorithm<br>Default is 0.        |
| NABS_SINGLETON_THRESHOLD | <code>TO_CHAR(0 &lt;= numeric_expr &lt;= 1)</code> | <code>TO_CHAR(0 &lt;= numeric_expr &lt;= 1)</code> | Value of singleton threshold for NB algorithm<br>Default value is 0. |

## 48.4.14 DBMS\_DATA\_MINING — Algorithm Settings: Neural Network

The settings listed in the following table configure the behavior of Neural Network.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.NNET_REGULARIZER_NONE`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'NNET_REGULARIZER_NONE'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-21 DBMS\_DATA\_MINING Neural Network Settings**

| Setting Name         | Constant Value              | String Value Equivalent     | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|-----------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NNET_HIDDEN_LAYERS   | Non-negative integer        | Non-negative integer        | Defines the topology by number of hidden layers.<br><br>The default value is 1.                                                                                                                                                                                                                                                                                                    |
| NNET_NODES_PER_LAYER | A list of positive integers | A list of positive integers | Defines the topology by number of nodes per layer. Different layers can have different number of nodes.<br><br>The value should be non-negative integers and comma separated. For example, '10, 20, 5'. The setting values must be consistent with NNET_HIDDEN_LAYERS. The default number of nodes per layer is the number of attributes or 50 (if the number of attributes > 50). |

|                         | NNET_ACTIVATIONS_B<br>IPOLAR_SIG | NNET_ACTIVATIONS_B<br>IPOLAR_SIG | Uses the bipolar sigmoid activation function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| NNET_WEIGHT_LOWER_BOUND | A real number                    | A real number                    | <p>The setting specifies the lower bound of the region where weights are randomly initialized. NNET_WEIGHT_LOWER_BOUND and NNET_WEIGHT_UPPER_BOUND must be set together. Setting one and not setting the other raises an error. NNET_WEIGHT_LOWER_BOUND must not be greater than NNET_WEIGHT_UPPER_BOUND. The default value is <math>-\sqrt{6/(l\_nodes+r\_nodes)}</math>. The value of <i>l_nodes</i> for:</p> <ul style="list-style-type: none"> <li>input layer dense attributes is (1+number of dense attributes)</li> <li>input layer sparse attributes is number of sparse attributes</li> <li>each hidden layer is (1+number of nodes in that hidden layer)</li> </ul> <p>The value of <i>r_nodes</i> is the number of nodes in the layer that the weight is connecting to.</p> |
| NNET_WEIGHT_UPPER_BOUND | A real number                    | A real number                    | <p>This setting specifies the upper bound of the region where weights are initialized. It should be set in pairs with NNET_WEIGHT_LOWER_BOUND and its value must not be smaller than the value of NNET_WEIGHT_LOWER_BOUND. If not specified, the values of NNET_WEIGHT_LOWER_BOUND and NNET_WEIGHT_UPPER_BOUND are system determined.</p> <p>The default value is <math>\sqrt{6/(l\_nodes+r\_nodes)}</math>. See NNET_WEIGHT_LOWER_BOUND.</p>                                                                                                                                                                                                                                                                                                                                          |
| NNET_ITERATIONS         | Positive integer                 | Positive integer                 | <p>This setting specifies the maximum number of iterations in the Neural Network algorithm.</p> <p>The default value is 200.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| NNET_TOLERANCE          | TO_CHAR(0<<br>numeric_expr <1)   | TO_CHAR(0<<br>numeric_expr <1)   | <p>Defines the convergence tolerance setting of the Neural Network algorithm.</p> <p>The default value is 0.000001.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Table 48-21 (Cont.) DBMS\_DATA\_MINING Neural Network Settings

| Setting Name            | Constant Value             | String Value Equivalent    | Description                                                                                                                                                                                                                        |
|-------------------------|----------------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NNET_REGULARIZER        | NNET_REGULARIZER_NONE      | NNET_REGULARIZER_NONE      | Regularization setting for Neural Network algorithm.<br><br>NNET_REGULARIZER_NONE: Disables regularization. If the total number of training rows is less than or equal to 50000, the default is NNET_REGULARIZER_NONE.             |
|                         | NNET_REGULARIZER_L2        | NNET_REGULARIZER_L2        | Applies L2 regularization, which penalizes the sum of squared weights.                                                                                                                                                             |
|                         | NNET_REGULARIZER_HELDASIDE | NNET_REGULARIZER_HELDASIDE | Uses a held-aside method for regularization. If the total number of training rows is greater than 50000, the default is NNET_REGULARIZER_HELDASIDE.                                                                                |
| NNET_HELDASIDE_RATIO    | 0 <= numeric_expr <=1      | 0 <= numeric_expr <=1      | Define the held ratio for the held-aside method. The default value is 0.25.                                                                                                                                                        |
| NNET_HELDASIDE_MAX_FAIL | A positive integer.        | A positive integer.        | With NNET_REGULARIZER_HELDASIDE, the training process is stopped early if the network performance on the validation data fails to improve or remains the same for NNET_HELDASIDE_MAX_FAIL epochs in a row. The default value is 6. |
| NNET_REG_LAMBDA         | TO_CHAR(numeric_expr >=0)  | TO_CHAR(numeric_expr >=0)  | Defines the L2 regularization parameter lambda. This can not be set together with NNET_REGULARIZER_HELDASIDE. The default value is 1.                                                                                              |

**Related Topics**

- [DBMS\\_DATA\\_MINING — Solver Settings: LBFGS](#)

The settings listed in the following table configure the behavior of L-BFGS. Neural Network and Generalized Linear Models (GLM) use these settings.

## 48.4.15 DBMS\_DATA\_MINING — Algorithm Settings: Non-Negative Matrix Factorization

The settings listed in the following table configure the behavior of the Non-negative Matrix Factorization algorithm.

The **Constant Value** column specifies constants using the prefix DBMS\_DATA\_MINING. For example, DBMS\_DATA\_MINING.NMFS\_NONNEG\_SCORING\_ENABLE. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the DBMS\_DATA\_MINING prefix, in single quotes. For example, 'NMFS\_NONNEG\_SCORING\_ENABLE'.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

You can query the data dictionary view `*_MINING_MODEL_SETTINGS` (using the `ALL`, `USER`, or `DBA` prefix) to find the setting values for a model. See *Oracle Database Reference* for information about `*_MINING_MODEL_SETTINGS`.

**Table 48-22 NMF Settings**

| Setting Name             | Constant Value                                       | String Value Equivalent                              | Description                                                                                                                                                                                                                        |

## 48.4.16 DBMS\_DATA\_MINING — Algorithm Settings: O-Cluster

The settings in the table configure the behavior of the O-Cluster algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.OCLT_SENSITIVITY`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'OCLT_SENSITIVITY'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-23 O-Cluster Settings**

| Setting Name     | Constant Value                      | String Value Equivalent             | Description                                                                                                                                              |
|------------------|-------------------------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| OCLT_SENSITIVITY | TO_CHAR(0<br><=numeric_expr<br><=1) | TO_CHAR(0<br><=numeric_expr<br><=1) | A fraction that specifies the peak density required for separating a new cluster. The fraction is related to the global uniform density. Default is 0.5. |

**See Also:**

*Oracle Data Mining Concepts* for information about O-Cluster

## 48.4.17 DBMS\_DATA\_MINING — Algorithm Settings: Random Forest

These settings configure the behavior of the Random Forest algorithm. Random Forest makes use of the Decision Tree settings to configure the construction of individual trees.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.RFOR_MTRY`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'RFOR_MTRY'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

**Table 48-24 Random Forest Settings**

| Setting Name   | Constant Value          | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                    |
|----------------|-------------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RFOR_MTRY      | a number >= 0           | a number >= 0           | Size of the random subset of columns to be considered when choosing a split at a node. For each node, the size of the pool remains the same, but the specific candidate columns change. The default is half of the columns in the model signature. The special value 0 indicates that the candidate pool includes all columns. |
| RFOR_NUM_TREES | 1<= a number<br><=65535 | 1<= a number<br><=65535 | Number of trees in the forest<br>Default is 20.                                                                                                                                                                                                                                                                                |

Table 48-24 (Cont.) Random Forest Settings

| Setting Name        | Constant Value                  | String Value Equivalent         | Description                                                                                                                                                             |
|---------------------|---------------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RFOR_SAMPLING_RATIO | $0 < a \text{ fraction} \leq 1$ | $0 < a \text{ fraction} \leq 1$ | Fraction of the training data to be randomly sampled for use in the construction of an individual tree. The default is half of the number of rows in the training data. |

**Related Topics**

- [DBMS\\_DATA\\_MINING — Algorithm Settings: Decision Tree](#)  
These settings configure the behavior of the Decision Tree algorithm. Note that the Decision Tree settings are also used to configure the behavior of Random Forest as it constructs each individual Decision Tree.

## 48.4.18 DBMS\_DATA\_MINING — Algorithm Constants and Settings: Singular Value Decomposition

The following constant affects the behavior of the Singular Value Decomposition algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.SVDS_MAX_NUM_FEATURES`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'SVDS_MAX_NUM_FEATURES'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

Table 48-25 Singular Value Decomposition Constant

| Constant Name         | Constant Value | Description                                      |
|-----------------------|----------------|--------------------------------------------------|
| SVDS_MAX_NUM_FEATURES | 2500           | The maximum number of features supported by SVD. |

The following settings configure the behavior of the Singular Value Decomposition algorithm.

**Table 48-26 Singular Value Decomposition Settings**

| Setting Name         | Constant Value        | String Value Equivalent | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVDS_U_MATRIX_OUTPUT | SVDS_U_MATRIX_ENABLE  | SVDS_U_MATRIX_ENABLE    | <p>Specifies whether to persist the <b>U</b> Matrix produced by SVD.</p> <p>SVDS_U_MATRIX_ENABLE: The U matrix in SVD has as many rows as the number of rows in the build data. To avoid creating a large model, the U matrix is persisted only when SVDS_U_MATRIX_OUTPUT is enabled.</p> <p>When SVDS_U_MATRIX_OUTPUT is enabled, the build data must include a case ID. An exception is raised if no case ID is present.</p> <p>Default is SVDS_U_MATRIX_DISABLE.</p> |
|                      | SVDS_U_MATRIX_DISABLE | SVDS_U_MATRIX_DISABLE   | Does not persist the U Matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| SVDS_SOLVER      | SVDS_SOLVER_TSSVD         | SVDS_SOLVER_TSSVD         | <p>This setting indicates the solver to be used for computing SVD of the data. In the case of PCA, the solver setting indicates the type of SVD solver used to compute the PCA for the data. When this setting is not specified the solver type selection is data driven. If the number of attributes is greater than 3240, then the default wide solver is used. Otherwise, the default narrow solver is selected.</p> <p>The following are the group of solvers:</p> <ul style="list-style-type: none"> <li>Narrow data solvers: for matrices with up to 11500 attributes (TSEIGEN) or up to 8100 attributes (TSSVD).</li> <li>Wide data solvers: for matrices up to 1 million attributes.</li> </ul> <p>For narrow data solvers:</p> <ul style="list-style-type: none"> <li>Tall-Skinny SVD uses QR computation TSVD (SVDS_SOLVER_TSSVD)</li> <li>Tall-Skinny SVD uses eigenvalue computation, TSEIGEN (SVDS_SOLVER_TSEIGEN), is the default solver for narrow data.</li> </ul> <p>For wide data solvers:</p> <ul style="list-style-type: none"> <li>Stochastic SVD uses QR computation SSVD (SVDS_SOLVER_SSVD), is the default solver for wide data solvers.</li> <li>Stochastic SVD uses eigenvalue computations, STEIGEN (SVDS_SOLVER_STEIGEN).</li> </ul> |
|                  | SVDS_SOLVER_TSEIGEN       | SVDS_SOLVER_TSEIGEN       | Tall-Skinny SVD using eigenvalue computation for matrices with up to 11500 attributes. This is the default solver for narrow data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                  | SVDS_SOLVER_SSVD          | SVDS_SOLVER_SSVD          | Stochastic SVD using QR computation for matrices with up to 1 million attributes. This is the default solver for wide data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                  | SVDS_SOLVER_STEIGEN       | SVDS_SOLVER_STEIGEN       | Stochastic SVD using eigenvalue computations for matrices with up to 1 million attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SVDS_TOLERANCE   | Range [0, 1]              | Range [0, 1]              | This setting is used to prune features. Define the minimum value the eigenvalue of a feature as a share of the first eigenvalue to not to prune. Default value is data driven.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SVDS_RANDOM_SEED | Range [0 - 4,294,967,296] | Range [0 - 4,294,967,296] | The random seed value is used for initializing the sampling matrix used by the Stochastic SVD solver. The default is 0. The SVD Solver must be set to SSVD or STEIGEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 48-26 (Cont.) Singular Value Decomposition Settings

| Setting Name          | Constant Value   | String Value Equivalent | Description                                                                                                                                                                                                                                                                |
|-----------------------|------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVDS_OVER_SAMPLING    | Range [1, 5000]. | Range [1, 5000].        | This setting is configured the number of columns in the sampling matrix used by the Stochastic SVD solver. The number of columns in this matrix is equal to the requested number of features plus the oversampling setting. The SVD Solver must be set to SSVD or STEIGEN. |
| SVDS_POWER_ITERATIONS | Range [0, 20].   | Range [0, 20].          | The power iteration setting improves the accuracy of the SSVD solver. The default is 2. The SVD Solver must be set to SSVD or STEIGEN.                                                                                                                                     |

## 48.4.19 DBMS\_DATA\_MINING — Algorithm Settings: Support Vector Machine

The settings listed in the following table configure the behavior of the Support Vector Machine algorithm.

The **Constant Value** column specifies constants using the prefix `DBMS_DATA_MINING`. For example, `DBMS_DATA_MINING.SVMS_GAUSSIAN`. Alternatively, you can specify the corresponding string value from the **String Value Equivalent** column without the `DBMS_DATA_MINING` prefix, in single quotes. For example, `'SVMS_GAUSSIAN'`.

**Note:**

The distinction between **Constant Value** and **String Value Equivalent** for this algorithm is applicable to Oracle Database 19c and Oracle Database 21c.

Table 48-27 SVM Settings

| Setting Name           | Constant Value                           | String Value Equivalent                  | Description                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVMS_COMPLEXITY_FACTOR | <code>TO_CHAR(numeric_exp &gt; 0)</code> | <code>TO_CHAR(numeric_exp &gt; 0)</code> | <p>Regularization setting that balances the complexity of the model against model robustness to achieve good generalization on new data. SVM uses a data-driven approach to finding the complexity factor.</p> <p>Value of complexity factor for SVM algorithm (both classification and regression).</p> <p>Default value estimated from the data by the algorithm.</p> |

**Table 48-27 (Cont.) SVM Settings**

| Setting Name         | Constant Value                | String Value Equivalent       | Description                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVMS_CONV_TOLERANCE  | TO_CHAR(numeric_expr > 0)     | TO_CHAR(numeric_expr > 0)     | Convergence tolerance for SVM algorithm.<br>Default is 0.0001.                                                                                                                                                                                                                                                                                  |
| SVMS_EPSILON         | TO_CHAR(numeric_expr > 0)     | TO_CHAR(numeric_expr > 0)     | Regularization setting for regression, similar to complexity factor. Epsilon specifies the allowable residuals, or noise, in the data.<br>Value of epsilon factor for SVM regression.<br>Default is 0.1.                                                                                                                                        |
| SVMS_KERNEL_FUNCTION | SVMS_GAUSSIAN                 | SVMS_GAUSSIAN                 | Kernel for Support Vector Machine. Linear or Gaussian.<br>SVMS_GAUSSIAN: Uses the Gaussian kernel for SVM.<br>The default value is SVMS_LINEAR.                                                                                                                                                                                                 |
|                      | SVMS_LINEAR                   | SVMS_LINEAR                   | Uses the Linear kernel for SVM. This is the default option.                                                                                                                                                                                                                                                                                     |
| SVMS_OUTLIER_RATE    | TO_CHAR(0 < numeric_expr < 1) | TO_CHAR(0 < numeric_expr < 1) | The desired rate of outliers in the training data. Valid for One-Class SVM models only (anomaly detection).<br>Default is 0.01.                                                                                                                                                                                                                 |
| SVMS_STD_DEV         | TO_CHAR(numeric_expr > 0)     | TO_CHAR(numeric_expr > 0)     | Controls the spread of the Gaussian kernel function. SVM uses a data-driven approach to find a standard deviation value that is on the same scale as distances between typical cases.<br>Value of standard deviation for SVM algorithm. This is applicable only for Gaussian kernel.<br>Default value estimated from the data by the algorithm. |
| SVMS_NUM_ITERATIONS  | Positive integer              | Positive integer              | This setting sets an upper limit on the number of SVM iterations. The default is system determined because it depends on the SVM solver.                                                                                                                                                                                                        |
| SVMS_NUM_PIVOTS      | Range [1; 10000]              | Range [1; 10000]              | This setting sets an upper limit on the number of pivots used in the Incomplete Cholesky decomposition. It can be set only for non-linear kernels. The default value is 200.                                                                                                                                                                    |
| SVMS_BATCH_ROWS      | Positive integer              | Positive integer              | This setting applies to SVM models with linear kernel. This setting sets the size of the batch for the SGD solver. An input of 0 triggers a data driven batch size estimate. The default is 20000.                                                                                                                                              |
| SVMS_REGULARIZER     | SVMS_REGULARIZER_L1           | SVMS_REGULARIZER_L1           | This setting controls the type of regularization that the SGD SVM solver uses. The setting can be used only for linear SVM models. The default is system determined because it depends on the potential model size.<br>SVMS_REGULARIZER_L1: Uses L1 regularization.                                                                             |
|                      | SVMS_REGULARIZER_L2           | SVMS_REGULARIZER_L2           | Uses L2 regularization.                                                                                                                                                                                                                                                                                                                         |

Table 48-27 (Cont.) SVM Settings

| Setting Name | Constant Value                             | String Value Equivalent                    | Description                                                                                                                                                                                        |
|--------------|--------------------------------------------|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVMS_SOLVER  | SVMS_SOLVER_SGD<br>(Sub-Gradient Descend)  | SVMS_SOLVER_SGD<br>(Sub-Gradient Descend)  | Enables to choose the SVM solver. The SGD solver cannot be selected if the kernel is non-linear. The default value is system determined.<br><br>SVMS_SOLVER_SGD: Uses Sub-Gradient Descent solver. |
|              | SVMS_SOLVER_IPM<br>(Interior Point Method) | SVMS_SOLVER_IPM<br>(Interior Point Method) | Uses Interior Point Method solver.                                                                                                                                                                 |

## 48.5 DBMS\_DATA\_MINING — Solver Settings

Oracle Data Mining algorithms can use different solvers. Solver settings can be provided at build time in the setting table.

**Related Topics**

- [DBMS\\_DATA\\_MINING — Solver Settings: ADMM](#)  
The settings listed in the following table configure the behavior of Alternating Direction Method of Multipliers (ADMM). Generalized Linear Models (GLM) use these settings.
- [DBMS\\_DATA\\_MINING — Solver Settings: LBFGS](#)  
The settings listed in the following table configure the behavior of L-BFGS. Neural Network and Generalized Linear Models (GLM) use these settings.

### 48.5.1 DBMS\_DATA\_MINING — Solver Settings: ADMM

The settings listed in the following table configure the behavior of Alternating Direction Method of Multipliers (ADMM). Generalized Linear Models (GLM) use these settings.

Table 48-28 DBMS\_DATA\_MINING ADMM Settings

| Settings Name   | Setting Value      | Description                                                                                        |
|-----------------|--------------------|----------------------------------------------------------------------------------------------------|
| ADMM_CONSENSUS  | A positive integer | It is a ADMM's consensus parameter. The value must be a positive number. The default value is 0.1. |
| ADMM_ITERATIONS | A positive integer | The number of ADMM iterations. The value must be a positive integer. The default value is 50.      |
| ADMM_TOLERANCE  | A positive integer | It is a tolerance parameter. The value must be a positive number. The default value is 0.0001      |

## 48.5.2 DBMS\_DATA\_MINING — Solver Settings: LBFGS

The settings listed in the following table configure the behavior of L-BFGS. Neural Network and Generalized Linear Models (GLM) use these settings.

**Table 48-29 DBMS\_DATA\_MINING L-BFGS Settings**

| Setting Name             | Setting Value                                             | Description                                                                                           |
|--------------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| LBFGS_GRADIENT_TOLERANCE | TO_CHAR (numeric_expr >0)                                 | Defines gradient infinity norm tolerance for L-BFGS. Default value is 1E-9.                           |
| LBFGS_HISTORY_DEPTH      | The value must be a positive integer.                     | Defines the number of historical copies kept in L-BFGS solver.<br>The default value is 20.            |
| LBFGS_SCALE_HESSIAN      | LBFGS_SCALE_HESSIAN_ENABLE<br>LBFGS_SCALE_HESSIAN_DISABLE | Defines whether to scale Hessian in L-BFGS or not.<br>Default value is<br>LBFGS_SCALE_HESSIAN_ENABLE. |

## 48.6 DBMS\_DATA\_MINING Datatypes

The DBMS\_DATA\_MINING package defines object datatypes for mining transactional data. The package also defines a type for user-specified transformations. These types are called DM\_NESTED\_n, where n identifies the Oracle datatype of the nested attributes.

The Data Mining object datatypes are described in the following table:

**Table 48-30 DBMS\_DATA\_MINING Summary of Datatypes**

| Datatype                 | Description                                                        |
|--------------------------|--------------------------------------------------------------------|
| DM_NESTED_BINARY_DOUBLE  | The name and value of a numerical attribute of type BINARY_DOUBLE. |
| DM_NESTED_BINARY_DOUBLES | A collection of DM_NESTED_BINARY_DOUBLE.                           |
| DM_NESTED_BINARY_FLOAT   | The name and value of a numerical attribute of type BINARY_FLOAT.  |

**Table 48-30 (Cont.) DBMS\_DATA\_MINING Summary of Datatypes**

| Datatype                | Description                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_NESTED_BINARY_FLOATS | A collection of DM_NESTED_BINARY_FLOAT.                                                                                                                                                                                     |
| DM_NESTED_CATEGORICAL   | The name and value of a categorical attribute of type CHAR, VARCHAR, or VARCHAR2.                                                                                                                                           |
| DM_NESTED_CATEGORICALS  | A collection of DM_NESTED_CATEGORICAL.                                                                                                                                                                                      |
| DM_NESTED_NUMERICAL     | The name and value of a numerical attribute of type NUMBER or FLOAT.                                                                                                                                                        |
| DM_NESTED_NUMERICALS    | A collection of DM_NESTED_NUMERICAL.                                                                                                                                                                                        |
| ORA_MINING_VARCHAR2_NT  | A table of VARCHAR2 (4000).                                                                                                                                                                                                 |
| TRANSFORM_LIST          | A list of user-specified transformations for a model. Accepted as a parameter by the <a href="#">CREATE_MODEL Procedure</a> .<br>This collection type is defined in the <a href="#">DBMS_DATA_MINING_TRANSFORM</a> package. |

For more information about mining nested data, see *Oracle Data Mining User's Guide*.

**Note:**

Starting from Oracle Database 12c Release 2, \*GET\_MODEL\_DETAILS are deprecated and are replaced with *Model Detail Views*. See *Oracle Data Mining User's Guide*.

## 48.6.1 Deprecated Types

This topic contains tables listing deprecated types.

The DBMS\_DATA\_MINING package defines object datatypes for storing information about model attributes. Most of these types are returned by the table functions GET\_n, where *n* identifies the type of information to return. These functions take a model name as input and return the requested information as a collection of rows.

For a list of the GET functions, see "[Summary of DBMS\\_DATA\\_MINING Subprograms](#)".

All the table functions use pipelining, which causes each row of output to be materialized as it is read from model storage, without waiting for the generation of the complete table object. For more information on pipelined, parallel table functions, consult the *Oracle Database PL/SQL Language Reference*.

**Table 48-31 DBMS\_DATA\_MINING Summary of Deprecated Datatypes**

| Datatype     | Description                                          |
|--------------|------------------------------------------------------|
| DM_CENTROID  | The centroid of a cluster.                           |
| DM_CENTROIDS | A collection of DM_CENTROID. A member of DM_CLUSTER. |
| DM_CHILD     | A child node of a cluster.                           |
| DM_CHILDREN  | A collection of DM_CHILD. A member of DM_CLUSTER.    |

**Table 48-31 (Cont.) DBMS\_DATA\_MINING Summary of Deprecated Datatypes**

| Datatype                | Description                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_CLUSTER              | A cluster. A cluster includes DM_PREDICATES, DM_CHILDREN, DM_CENTROIDS, and DM_HISTOGRAMS. It also includes a DM_RULE.<br>See also, <a href="#">DM_CLUSTER Fields</a> .                                                                      |
| DM_CLUSTERS             | A collection of DM_CLUSTER. Returned by <a href="#">GET_MODEL_DETAILS_KM Function</a> , <a href="#">GET_MODEL_DETAILS_OC Function</a> , and <a href="#">GET_MODEL_DETAILS_EM Function</a> .<br>See also, <a href="#">DM_CLUSTER Fields</a> . |
| DM_CONDITIONAL          | The conditional probability of an attribute in a Naive Bayes model.                                                                                                                                                                          |
| DM_CONDITIONALS         | A collection of DM_CONDITIONAL. Returned by <a href="#">GET_MODEL_DETAILS_NB Function</a> .                                                                                                                                                  |
| DM_COST_ELEMENT         | The actual and predicted values in a cost matrix.                                                                                                                                                                                            |
| DM_COST_MATRIX          | A collection of DM_COST_ELEMENT. Returned by <a href="#">GET_MODEL_COST_MATRIX Function</a> .                                                                                                                                                |
| DM_EM_COMPONENT         | A component of an Expectation Maximization model.                                                                                                                                                                                            |
| DM_EM_COMPONENT_SET     | A collection of DM_EM_COMPONENT. Returned by <a href="#">GET_MODEL_DETAILS_EM_COMP Function</a> .                                                                                                                                            |
| DM_EM_PROJECTION        | A projection of an Expectation Maximization model.                                                                                                                                                                                           |
| DM_EM_PROJECTION_SET    | A collection of DM_EM_PROJECTION. Returned by <a href="#">GET_MODEL_DETAILS_EM_PROJ Function</a> .                                                                                                                                           |
| DM_GLM_COEFF            | The coefficient and associated statistics of an attribute in a Generalized Linear Model.                                                                                                                                                     |
| DM_GLM_COEFF_SET        | A collection of DM_GLM_COEFF. Returned by <a href="#">GET_MODEL_DETAILS_GLM Function</a> .                                                                                                                                                   |
| DM_HISTOGRAM_BIN        | A histogram associated with a cluster.                                                                                                                                                                                                       |
| DM_HISTOGRAMS           | A collection of DM_HISTOGRAM_BIN. A member of DM_CLUSTER.<br>See also, <a href="#">DM_CLUSTER Fields</a> .                                                                                                                                   |
| DM_ITEM                 | An item in an association rule.                                                                                                                                                                                                              |
| DM_ITEMS                | A collection of DM_ITEM.                                                                                                                                                                                                                     |
| DM_ITEMSET              | A collection of DM_ITEMS.                                                                                                                                                                                                                    |
| DM_ITEMSETS             | A collection of DM_ITEMSET. Returned by <a href="#">GET_FREQUENT_ITEMSETS Function</a> .                                                                                                                                                     |
| DM_MODEL_GLOBAL_DETAIL  | High-level statistics about a model.                                                                                                                                                                                                         |
| DM_MODEL_GLOBAL_DETAILS | A collection of DM_MODEL_GLOBAL_DETAIL. Returned by <a href="#">GET_MODEL_DETAILS_GLOBAL Function</a> .                                                                                                                                      |
| DM_NB_DETAIL            | Information about an attribute in a Naive Bayes model.                                                                                                                                                                                       |
| DM_NB_DETAILS           | A collection of DM_NB_DETAIL. Returned by <a href="#">GET_MODEL_DETAILS_NB Function</a> .                                                                                                                                                    |
| DM_NMF_ATTRIBUTE        | An attribute in a feature of a Non-Negative Matrix Factorization model.                                                                                                                                                                      |
| DM_NMF_ATTRIBUTE_SET    | A collection of DM_NMF_ATTRIBUTE. A member of DM_NMF_FEATURE.                                                                                                                                                                                |

**Table 48-31 (Cont.) DBMS\_DATA\_MINING Summary of Deprecated Datatypes**

| Datatype                | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_NMF_FEATURE          | A feature in a Non-Negative Matrix Factorization model.                                                                                                                                                                                                                                                                                                                                                 |
| DM_NMF_FEATURE_SET      | A collection of DM_NMF_FEATURE. Returned by <a href="#">GET_MODEL_DETAILS_NMF Function</a> .                                                                                                                                                                                                                                                                                                            |
| DM_PREDICATE            | Antecedent and consequent in a rule.                                                                                                                                                                                                                                                                                                                                                                    |
| DM_PREDICATES           | A collection of DM_PREDICATE. A member of DM_RULE and DM_CLUSTER. Predicates are returned by <a href="#">GET_ASSOCIATION_RULES Function</a> , <a href="#">GET_MODEL_DETAILS_EM Function</a> , <a href="#">GET_MODEL_DETAILS_KM Function</a> , and <a href="#">GET_MODEL_DETAILS_OC Function</a> .<br>See also, <a href="#">DM_CLUSTER Fields</a> .                                                      |
| DM_RANKED_ATTRIBUTE     | An attribute ranked by its importance in an Attribute Importance model.                                                                                                                                                                                                                                                                                                                                 |
| DM_RANKED_ATTRIBUTES    | A collection of DM_RANKED_ATTRIBUTE. Returned by <a href="#">GET_MODEL_DETAILS_AI Function</a> .                                                                                                                                                                                                                                                                                                        |
| DM_RULE                 | A rule that defines a conditional relationship.<br>The rule can be one of the association rules returned by <a href="#">GET_ASSOCIATION_RULES Function</a> , or it can be a rule associated with a cluster in the collection of clusters returned by <a href="#">GET_MODEL_DETAILS_KM Function</a> and <a href="#">GET_MODEL_DETAILS_OC Function</a> .<br>See also, <a href="#">DM_CLUSTER Fields</a> . |
| DM_RULES                | A collection of DM_RULE. Returned by <a href="#">GET_ASSOCIATION_RULES Function</a> .<br>See also, <a href="#">DM_CLUSTER Fields</a> .                                                                                                                                                                                                                                                                  |
| DM_SVD_MATRIX           | A factorized matrix S, V, or U returned by a Singular Value Decomposition model.                                                                                                                                                                                                                                                                                                                        |
| DM_SVD_MATRIX_SET       | A collection of DM_SVD_MATRIX. Returned by <a href="#">GET_MODEL_DETAILS_SVD Function</a> .                                                                                                                                                                                                                                                                                                             |
| DM_SVM_ATTRIBUTE        | The name, value, and coefficient of an attribute in a Support Vector Machine model.                                                                                                                                                                                                                                                                                                                     |
| DM_SVM_ATTRIBUTE_SET    | A collection of DM_SVM_ATTRIBUTE. Returned by <a href="#">GET_MODEL_DETAILS_SVM Function</a> . Also a member of DM_SVM_LINEAR_COEFF.                                                                                                                                                                                                                                                                    |
| DM_SVM_LINEAR_COEFF     | The linear coefficient of each attribute in a Support Vector Machine model.                                                                                                                                                                                                                                                                                                                             |
| DM_SVM_LINEAR_COEFF_SET | A collection of DM_SVM_LINEAR_COEFF. Returned by <a href="#">GET_MODEL_DETAILS_SVM Function</a> for an SVM model built using the linear kernel.                                                                                                                                                                                                                                                         |
| DM_TRANSFORM            | The transformation and reverse transformation expressions for an attribute.                                                                                                                                                                                                                                                                                                                             |
| DM_TRANSFORMS           | A collection of DM_TRANSFORM. Returned by <a href="#">GET_MODEL_TRANSFORMATIONS Function</a> .                                                                                                                                                                                                                                                                                                          |

## Return Values for Clustering Algorithms

The table contains description of `DM_CLUSTER` return value columns, nested table columns, and rows.

**Table 48-32** `DM_CLUSTER` Return Values for Clustering Algorithms

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DM_CLUSTERS</code>  | <p>A set of rows of type <code>DM_CLUSTER</code>. The rows have the following columns:</p> <pre>(id          NUMBER,  cluster_id  VARCHAR2(4000),  record_count NUMBER,  parent      NUMBER,  tree_level  NUMBER,  dispersion  NUMBER,  split_predicate DM_PREDICATES,  child       DM_CHILDREN,  centroid    DM_CENTROIDS,  histogram   DM_HISTOGRAMS,  rule        DM_RULE)</pre>                                                                                                   |
| <code>DM_PREDICATE</code> | <p>The antecedent and consequent columns each return nested tables of type <code>DM_PREDICATES</code>. The rows, of type <code>DM_PREDICATE</code>, have the following columns:</p> <pre>(attribute_name      VARCHAR2(4000),  attribute_subname    VARCHAR2(4000),  conditional_operator CHAR(2) /*=, &lt;&gt;, &lt;, &gt;, &lt;=, &gt;=*/,  attribute_num_value  NUMBER,  attribute_str_value   VARCHAR2(4000),  attribute_support     NUMBER,  attribute_confidence  NUMBER)</pre> |

## `DM_CLUSTER` Fields

The following table describes `DM_CLUSTER` fields.

**Table 48-33** `DM_CLUSTER` Fields

| Column Name               | Description                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>           | Cluster identifier                                                                                                       |
| <code>cluster_id</code>   | The ID of a cluster in the model                                                                                         |
| <code>record_count</code> | Specifies the number of records                                                                                          |
| <code>parent</code>       | Parent ID                                                                                                                |
| <code>tree_level</code>   | Specifies the number of splits from the root                                                                             |
| <code>dispersion</code>   | A measure used to quantify whether a set of observed occurrences are dispersed compared to a standard statistical model. |

**Table 48-33 (Cont.) DM\_CLUSTER Fields**

| Column Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| split_predicate | <p>The split_predicate column of DM_CLUSTER returns a nested table of type DM_PREDICATES. Each row, of type DM_PREDICATE, has the following columns:</p> <pre> (attribute_name      VARCHAR2(4000),  attribute_subname   VARCHAR2(4000),  conditional_operator CHAR(2) /  *=,&lt;&gt;,&lt;,&gt;,&lt;=,&gt;=*/ ,  attribute_num_value  NUMBER,  attribute_str_value  VARCHAR2(4000),  attribute_support    NUMBER,  attribute_confidence NUMBER)</pre> <p>Note: The Expectation Maximization algorithm uses all the fields except dispersion and split_predicate.</p> |
| child           | The child column of DM_CLUSTER returns a nested table of type DM_CHILDREN. The rows, of type DM_CHILD, have a single column of type NUMBER, which contains the identifiers of each child.                                                                                                                                                                                                                                                                                                                                                                            |
| centroid        | <p>The centroid column of DM_CLUSTER returns a nested table of type DM_CENTROIDS. The rows, of type DM_CENTROID, have the following columns:</p> <pre> (attribute_name      VARCHAR2(4000),  attribute_subname   VARCHAR2(4000),  mean                NUMBER,  mode_value          VARCHAR2(4000),  variance            NUMBER)</pre>                                                                                                                                                                                                                                |
| histogram       | <p>The histogram column of DM_CLUSTER returns a nested table of type DM_HISTOGRAMS. The rows, of type DM_HISTOGRAM_BIN, have the following columns:</p> <pre> (attribute_name      VARCHAR2(4000),  attribute_subname   VARCHAR2(4000),  bin_id              NUMBER,  lower_bound         NUMBER,  upper_bound         NUMBER,  label               VARCHAR2(4000),  count               NUMBER)</pre>                                                                                                                                                               |
| rule            | <p>The rule column of DM_CLUSTER returns a single row of type DM_RULE. The columns are:</p> <pre> (rule_id             INTEGER,  antecedent           DM_PREDICATES,  consequent           DM_PREDICATES,  rule_support         NUMBER,  rule_confidence      NUMBER,  rule_lift            NUMBER,  antecedent_support   NUMBER,  consequent_support   NUMBER,  number_of_items      INTEGER)</pre>                                                                                                                                                                 |

### Usage Notes

- The table function pipes out rows of type `DM_CLUSTER`. For information on Data Mining datatypes and piped output from table functions, see "[Datatypes](#)".
- For descriptions of predicates (`DM_PREDICATE`) and rules (`DM_RULE`), see [GET\\_ASSOCIATION\\_RULES Function](#).

## 48.7 Summary of DBMS\_DATA\_MINING Subprograms

This table summarizes the subprograms included in the `DBMS_DATA_MINING` package.

The `GET_*` interfaces are replaced by model views. Oracle recommends that users leverage model detail views instead. For more information, refer to "Model Detail Views" in *Oracle Data Mining User's Guide* and "Static Data Dictionary Views: `ALL_ALL_TABLES` to `ALL_OUTLINES`" in *Oracle Database Reference*.

**Table 48-34 DBMS\_DATA\_MINING Package Subprograms**

| Subprogram                                                  | Purpose                                                                         |
|-------------------------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">ADD_COST_MATRIX Procedure</a>                   | Adds a cost matrix to a classification model                                    |
| <a href="#">ADD_PARTITION Procedure</a>                     | Adds single or multiple partitions in an existing partition model               |
| <a href="#">ALTER_REVERSE_EXPRESSION Procedure</a>          | Changes the reverse transformation expression to an expression that you specify |
| <a href="#">APPLY Procedure</a>                             | Applies a model to a data set (scores the data)                                 |
| <a href="#">COMPUTE_CONFUSION_MATRIX Procedure</a>          | Computes the confusion matrix for a classification model                        |
| <a href="#">COMPUTE_CONFUSION_MATRIX_PART Procedure</a>     | Computes the evaluation matrix for partitioned models                           |
| <a href="#">COMPUTE_LIFT Procedure</a>                      | Computes lift for a classification model                                        |
| <a href="#">COMPUTE_LIFT_PART Procedure</a>                 | Computes lift for partitioned models                                            |
| <a href="#">COMPUTE_ROC Procedure</a>                       | Computes Receiver Operating Characteristic (ROC) for a classification model     |
| <a href="#">COMPUTE_ROC_PART Procedure</a>                  | Computes Receiver Operating Characteristic (ROC) for a partitioned model        |
| <a href="#">CREATE_MODEL Procedure</a>                      | Creates a model                                                                 |
| <a href="#">CREATE_MODEL2 Procedure</a>                     | Creates a model without extra persistent stages                                 |
| <a href="#">Create Model Using Registration Information</a> | Fetches setting information from JSON object                                    |
| <a href="#">DROP_ALGORITHM Procedure</a>                    | Drops the registered algorithm information.                                     |
| <a href="#">DROP_PARTITION Procedure</a>                    | Drops a single partition                                                        |
| <a href="#">DROP_MODEL Procedure</a>                        | Drops a model                                                                   |
| <a href="#">EXPORT_MODEL Procedure</a>                      | Exports a model to a dump file                                                  |
| <a href="#">EXPORT_SERMODEL Procedure</a>                   | Exports a model in a serialized format                                          |
| <a href="#">FETCH_JSON_SCHEMA Procedure</a>                 | Fetches and reads JSON schema from <code>all_mining_algorithms</code> view      |
| <a href="#">GET_MODEL_COST_MATRIX Function</a>              | Returns the cost matrix for a model                                             |
| <a href="#">IMPORT_MODEL Procedure</a>                      | Imports a model into a user schema                                              |

**Table 48-34 (Cont.) DBMS\_DATA\_MINING Package Subprograms**

| Subprogram                                             | Purpose                                                                              |
|--------------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">IMPORT_SERMODEL Procedure</a>              | Imports a serialized model back into the database                                    |
| <a href="#">JSON Schema for R Extensible Algorithm</a> | Displays flexibility in creating JSON schema for R Extensible                        |
| <a href="#">REGISTER_ALGORITHM Procedure</a>           | Registers a new algorithm                                                            |
| <a href="#">RANK_APPLY Procedure</a>                   | Ranks the predictions from the <code>APPLY</code> results for a classification model |
| <a href="#">REMOVE_COST_MATRIX Procedure</a>           | Removes a cost matrix from a model                                                   |
| <a href="#">RENAME_MODEL Procedure</a>                 | Renames a model                                                                      |

#### Deprecated GET\_MODEL\_DETAILS

Starting from Oracle Database 12c Release 2, the following `GET_MODEL_DETAILS` are deprecated:

**Table 48-35 Deprecated GET\_MODEL\_DETAILS Functions**

| Subprogram                                         | Purpose                                                                                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GET_ASSOCIATION_RULES Function</a>     | Returns the rules from an association model                                                                                                |
| <a href="#">GET_FREQUENT_ITEMSETS Function</a>     | Returns the frequent itemsets for an association model                                                                                     |
| <a href="#">GET_MODEL_DETAILS_AI Function</a>      | Returns details about an Attribute Importance model                                                                                        |
| <a href="#">GET_MODEL_DETAILS_EM Function</a>      | Returns details about an Expectation Maximization model                                                                                    |
| <a href="#">GET_MODEL_DETAILS_EM_COMP Function</a> | Returns details about the parameters of an Expectation Maximization model                                                                  |
| <a href="#">GET_MODEL_DETAILS_EM_PROJ Function</a> | Returns details about the projects of an Expectation Maximization model                                                                    |
| <a href="#">GET_MODEL_DETAILS_GLM Function</a>     | Returns details about a Generalized Linear Model                                                                                           |
| <a href="#">GET_MODEL_DETAILS_GLOBAL Function</a>  | Returns high-level statistics about a model                                                                                                |
| <a href="#">GET_MODEL_DETAILS_KM Function</a>      | Returns details about a <i>k</i> -Means model                                                                                              |
| <a href="#">GET_MODEL_DETAILS_NB Function</a>      | Returns details about a Naive Bayes model                                                                                                  |
| <a href="#">GET_MODEL_DETAILS_NMF Function</a>     | Returns details about a Non-Negative Matrix Factorization model                                                                            |
| <a href="#">GET_MODEL_DETAILS_OC Function</a>      | Returns details about an O-Cluster model                                                                                                   |
| <a href="#">GET_MODEL_SETTINGS Function</a>        | Returns the settings used to build the given model<br>This function is replaced with <code>USER/ALL/DBA_MINING_MODEL_SETTINGS</code>       |
| <a href="#">GET_MODEL_SIGNATURE Function</a>       | Returns the list of columns from the build input table<br>This function is replaced with <code>USER/ALL/DBA_MINING_MODEL_ATTRIBUTES</code> |
| <a href="#">GET_MODEL_DETAILS_SVD Function</a>     | Returns details about a Singular Value Decomposition model                                                                                 |

**Table 48-35 (Cont.) Deprecated GET\_MODEL\_DETAILS Functions**

| Subprogram                                         | Purpose                                                                                                                         |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">GET_MODEL_DETAILS_SVM Function</a>     | Returns details about a Support Vector Machine model with a linear kernel                                                       |
| <a href="#">GET_MODEL_TRANSFORMATIONS Function</a> | Returns the transformations embedded in a model<br>This function is replaced with <code>USER/ALL/DBA_MINING_MODEL_XFORMS</code> |
| <a href="#">GET_MODEL_DETAILS_XML Function</a>     | Returns details about a Decision Tree model                                                                                     |
| <a href="#">GET_TRANSFORM_LIST Procedure</a>       | Converts between two different transformation specification formats                                                             |

## 48.7.1 ADD\_COST\_MATRIX Procedure

The `ADD_COST_MATRIX` procedure associates a cost matrix table with a Classification model. The cost matrix biases the model by assigning costs or benefits to specific model outcomes.

The cost matrix is stored with the model and taken into account when the model is scored.

You can also specify a cost matrix inline when you invoke a Data Mining SQL function for scoring. To view the scoring matrix for a model, query the `DM$VC` prefixed model view. Refer to Model Detail View for Classification Algorithm.

To obtain the default scoring matrix for a model, query the `DM$VC` prefixed model view. To remove the default scoring matrix from a model, use the `REMOVE_COST_MATRIX` procedure. See "[GET\\_MODEL\\_COST\\_MATRIX Function](#)" and "[REMOVE\\_COST\\_MATRIX Procedure](#)".

**See Also:**

- "Biasing a Classification Model" in *Oracle Data Mining Concepts* for more information about costs
- *Oracle Database SQL Language Reference* for syntax of inline cost matrix
- *Oracle Data Mining User's Guide*

**Syntax**

```
DBMS_DATA_MINING.ADD_COST_MATRIX (  
    model_name           IN VARCHAR2,  
    cost_matrix_table_name IN VARCHAR2,  
    cost_matrix_schema_name IN VARCHAR2 DEFAULT NULL);  
partition_name          IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 48-36 ADD\_COST\_MATRIX Procedure Parameters**

| Parameter                            | Description                                                                                                                            |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>              | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is assumed. |
| <code>cost_matrix_table_name</code>  | Name of the cost matrix table (described in <a href="#">Table 48-37</a> ).                                                             |
| <code>cost_matrix_schema_name</code> | Schema of the cost matrix table. If no schema is specified, then the current schema is used.                                           |
| <code>partition_name</code>          | Name of the partition in a partitioned model                                                                                           |

## Usage Notes

1. If the model is not in your schema, then `ADD_COST_MATRIX` requires the `ALTER ANY MINING MODEL` system privilege or the `ALTER` object privilege for the mining model.
2. The cost matrix table must have the columns shown in [Table 48-37](#).

**Table 48-37 Required Columns in a Cost Matrix Table**

| Column Name                         | Datatype                                      |
|-------------------------------------|-----------------------------------------------|
| <code>ACTUAL_TARGET_VALUE</code>    | Valid target data type                        |
| <code>PREDICTED_TARGET_VALUE</code> | Valid target data type                        |
| <code>COST</code>                   | NUMBER, FLOAT, BINARY_DOUBLE, or BINARY_FLOAT |

### See Also:

*Oracle Data Mining User's Guide* for valid target datatypes

3. The types of the actual and predicted target values must be the same as the type of the model target. For example, if the target of the model is `BINARY_DOUBLE`, then the actual and predicted values must be `BINARY_DOUBLE`. If the actual and predicted values are `CHAR` or `VARCHAR`, then `ADD_COST_MATRIX` treats them as `VARCHAR2` internally.

If the types do not match, or if the actual or predicted value is not a valid target value, then the `ADD_COST_MATRIX` procedure raises an error.

### Note:

If a reverse transformation is associated with the target, then the actual and predicted values must be consistent with the target after the reverse transformation has been applied.

See “Reverse Transformations and Model Transparency” under the “About Transformation Lists” section in [DBMS\\_DATA\\_MINING\\_TRANSFORM Operational Notes](#) for more information.

4. Since a benefit can be viewed as a negative cost, you can specify a benefit for a given outcome by providing a negative number in the `costs` column of the cost matrix table.
5. All Classification algorithms can use a cost matrix for scoring. The Decision Tree algorithm can also use a cost matrix at build time. If you want to build a Decision Tree model with a cost matrix, specify the cost matrix table name in the `CLAS_COST_TABLE_NAME` setting in the settings table for the model. See [Table 48-7](#).

The cost matrix used to create a Decision Tree model becomes the default scoring matrix for the model. If you want to specify different costs for scoring, use the `REMOVE_COST_MATRIX` procedure to remove the cost matrix and the `ADD_COST_MATRIX` procedure to add a new one.

6. Scoring on a partitioned model is partition-specific. Scoring cost matrices can be added to or removed from an individual partition in a partitioned model. If `PARTITION_NAME` is NOT NULL, then the model must be a partitioned model. The `COST_MATRIX` is added to that partition of the partitioned model.

If the `PARTITION_NAME` is NULL, but the model is a partitioned model, then the `COST_MATRIX` table is added to every partition in the model.

### Example

This example creates a cost matrix table called `COSTS_NB` and adds it to a Naive Bayes model called `NB_SH_CLAS_SAMPLE`. The model has a binary target: 1 means that the customer responds to a promotion; 0 means that the customer does not respond. The cost matrix assigns a cost of .25 to misclassifications of customers who do not respond and a cost of .75 to misclassifications of customers who do respond. This means that it is three times more costly to misclassify responders than it is to misclassify non-responders.

```
CREATE TABLE costs_nb (
  actual_target_value      NUMBER,
  predicted_target_value   NUMBER,
  cost                     NUMBER);
INSERT INTO costs_nb values (0, 0, 0);
INSERT INTO costs_nb values (0, 1, .25);
INSERT INTO costs_nb values (1, 0, .75);
INSERT INTO costs_nb values (1, 1, 0);
COMMIT;

EXEC dbms_data_mining.add_cost_matrix('nb_sh_clas_sample', 'costs_nb');
```

```
SELECT cust_gender, COUNT(*) AS cnt, ROUND(AVG(age)) AS avg_age
FROM mining_data_apply_v
WHERE PREDICTION(nb_sh_clas_sample COST MODEL
  USING cust_marital_status, education, household_size) = 1
GROUP BY cust_gender
ORDER BY cust_gender;
```

| C | CNT | AVG_AGE |
|---|-----|---------|
| F | 72  | 39      |
| M | 555 | 44      |

## 48.7.2 ADD\_PARTITION Procedure

`ADD_PARTITION` procedure supports a single or multiple partition addition to an existing partitioned model.

The `ADD_PARTITION` procedure derives build settings and user-defined expressions from the existing model. The target column must exist in the input data query when adding partitions to a supervised model.

### Syntax

```
DBMS_DATA_MINING.ADD_PARTITION (
    model_name          IN VARCHAR2,
    data_query          IN CLOB,
    add_options         IN VARCHAR2 DEFAULT ERROR);
```

### Parameters

**Table 48-38 ADD\_PARTITION Procedure Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>  | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>data_query</code>  | An arbitrary SQL statement that provides data to the model build. The user must have privilege to evaluate this query.                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>add_options</code> | Allows users to control the conditional behavior of ADD for cases where rows in the input dataset conflict with existing partitions in the model. The following are the possible values: <ul style="list-style-type: none"> <li><code>REPLACE</code>: Replaces the existing partition for which the conflicting keys are found.</li> <li><code>ERROR</code>: Terminates the ADD operation without adding any partitions.</li> <li><code>IGNORE</code>: Eliminates the rows having the conflicting keys.</li> </ul> |

#### Note:

For better performance, Oracle recommends using `DROP_PARTITION` followed by the `ADD_PARTITION` instead of using the `REPLACE` option.

## 48.7.3 ALTER\_REVERSE\_EXPRESSION Procedure

This procedure replaces a reverse transformation expression with an expression that you specify. If the attribute does not have a reverse expression, the procedure creates one from the specified expression.

You can also use this procedure to customize the output of clustering, feature extraction, and anomaly detection models.

## Syntax

```
DBMS_DATA_MINING.ALTER_REVERSE_EXPRESSION (
    model_name          VARCHAR2,
    expression          CLOB,
    attribute_name       VARCHAR2 DEFAULT NULL,
    attribute_subname    VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 48-39 ALTER\_REVERSE\_EXPRESSION Procedure Parameters**

| Parameter         | Description                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------|
| model_name        | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, your own schema is used.               |
| expression        | An expression to replace the reverse transformation associated with the attribute.                                             |
| attribute_name    | Name of the attribute. Specify NULL if you wish to apply <i>expression</i> to a cluster, feature, or One-Class SVM prediction. |
| attribute_subname | Name of the nested attribute if <i>attribute_name</i> is a nested column, otherwise NULL.                                      |

## Usage Notes

- For purposes of model transparency, Oracle Data Mining provides reverse transformations for transformations that are embedded in a model. Reverse transformations are applied to the attributes returned in model details (GET\_MODEL\_DETAILS\_\* functions) and to the scored target of predictive models.

### See Also:

"About Transformation Lists" under [DBMS\\_DATA\\_MINING\\_TRANSFORM Operational Notes](#)

- If you alter the reverse transformation for the target of a model that has a cost matrix, you must specify a transformation expression that has the same type as the actual and predicted values in the cost matrix. Also, the reverse transformation that you specify must result in values that are present in the cost matrix.

### See Also:

"[ADD\\_COST\\_MATRIX Procedure](#)" and *Oracle Data Mining Concepts* for information about cost matrixes.

- To prevent reverse transformation of an attribute, you can specify NULL for *expression*.
- The reverse transformation expression can contain a reference to a PL/SQL function that returns a valid Oracle datatype. For example, you could define a function like the following for a categorical attribute named blood\_pressure that has values 'Low', 'Medium' and 'High'.

```
CREATE OR REPLACE FUNCTION numx(c char) RETURN NUMBER IS
BEGIN
  CASE c WHEN 'Low' THEN RETURN 1;
        WHEN 'Medium' THEN RETURN 2;
        WHEN 'High' THEN RETURN 3;
        ELSE RETURN null;
  END CASE;
END numx;
```

Then you could invoke ALTER\_REVERSE\_EXPRESSION for blood\_pressure as follows.

```
EXEC dbms_data_mining.alter_reverse_expression(
    '<model_name>', 'NUMX(blood_pressure)', 'blood_pressure');
```

5. You can use ALTER\_REVERSE\_EXPRESSION to label clusters produced by clustering models and features produced by feature extraction.

You can use ALTER\_REVERSE\_EXPRESSION to replace the zeros and ones returned by anomaly-detection models. By default, anomaly-detection models label anomalous records with 0 and all other records with 1.

### See Also:

*Oracle Data Mining Concepts* for information about anomaly detection

## Examples

1. In this example, the target (affinity\_card) of the model CLASS\_MODEL is manipulated internally as yes or no instead of 1 or 0 but returned as 1s and 0s when scored. The ALTER\_REVERSE\_EXPRESSION procedure causes the target values to be returned as TRUE or FALSE.

The data sets MINING\_DATA\_BUILD and MINING\_DATA\_TEST are included with the Oracle Data Mining sample programs. See *Oracle Data Mining User's Guide* for information about the sample programs.

```
DECLARE
  v_xlst dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
  dbms_data_mining_transform.SET_TRANSFORM(v_xlst,
    'affinity_card', NULL,
    'decode(affinity_card, 1, 'yes', 'no')',
    'decode(affinity_card, 'yes', 1, 0)');
  dbms_data_mining.CREATE_MODEL(
    model_name          => 'CLASS_MODEL',
    mining_function      => dbms_data_mining.classification,
    data_table_name     => 'mining_data_build',
    case_id_column_name => 'cust_id',
    target_column_name  => 'affinity_card',
    settings_table_name => NULL,
    data_schema_name    => 'dmuser',
    settings_schema_name => NULL,
    xform_list          => v_xlst );
END;
/
SELECT cust_income_level, occupation,
       PREDICTION(CLASS_MODEL USING *) predict_response
FROM   mining_data_test WHERE age = 60 AND cust_gender IN 'M'
ORDER BY cust_income_level;
```

| CUST_INCOME_LEVEL    | OCCUPATION | PREDICT_RESPONSE |

100008 Cluster 14
100009 Cluster 8
100010 Cluster 8

```

## 48.7.4 APPLY Procedure

The `APPLY` procedure applies a mining model to the data of interest, and generates the results in a table. The `APPLY` procedure is also referred to as **scoring**.

For predictive mining functions, the `APPLY` procedure generates predictions in a target column. For descriptive mining functions such as Clustering, the `APPLY` process assigns each case to a cluster with a probability.

In Oracle Data Mining, the `APPLY` procedure is not applicable to Association models and Attribute Importance models.

### Note:

Scoring can also be performed directly in SQL using the Data Mining functions. See

- "Data Mining Functions" in *Oracle Database SQL Language Reference*
- "Scoring and Deployment" in *Oracle Data Mining User's Guide*

### Syntax

```
DBMS_DATA_MINING.APPLY (
    model_name           IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    case_id_column_name  IN VARCHAR2,
    result_table_name    IN VARCHAR2,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 48-40** *APPLY Procedure Parameters*

| Parameter                        | Description                                                                                                                         |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>          | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>data_table_name</code>     | Name of table or view containing the data to be scored                                                                              |
| <code>case_id_column_name</code> | Name of the case identifier column                                                                                                  |
| <code>result_table_name</code>   | Name of the table in which to store apply results                                                                                   |
| <code>data_schema_name</code>    | Name of the schema containing the data to be scored                                                                                 |

### Usage Notes

1. The data provided for `APPLY` must undergo the same preprocessing as the data used to create and test the model. When you use Automatic Data Preparation, the preprocessing required by the algorithm is handled for you by the model: both at build time and apply time. (See "[Automatic Data Preparation](#)".)
2. `APPLY` creates a table in the user's schema to hold the results. The columns are algorithm-specific.

The columns in the results table are listed in [Table 48-41](#) through [Table 48-45](#). The case ID column name in the results table will match the case ID column name provided by you. The type of the incoming case ID column is also preserved in `APPLY` output.

 **Note:**

Make sure that the case ID column does not have the same name as one of the columns that will be created by `APPLY`. For example, when applying a Classification model, the case ID in the scoring data must not be `PREDICTION` or `PROBABILITY` (See [Table 48-41](#)).

3. The datatype for the `PREDICTION`, `CLUSTER_ID`, and `FEATURE_ID` output columns is influenced by any reverse expression that is embedded in the model by the user. If the user does not provide a reverse expression that alters the scored value type, then the types will conform to the descriptions in the following tables. See "[ALTER\\_REVERSE\\_EXPRESSION Procedure](#)".
4. If the model is partitioned, the `result_table_name` can contain results from different partitions depending on the data from the input data table. An additional column called `PARTITION_NAME` is added to the result table indicating the partition name that is associated with each row.

For a non-partitioned model, the behavior does not change.

### Classification

The results table for Classification has the columns described in [Table 48-41](#). If the target of the model is categorical, the `PREDICTION` column will have a `VARCHAR2` datatype. If the target has a binary type, the `PREDICTION` column will have the binary type of the target.

**Table 48-41 APPLY Results Table for Classification**

| Column Name                | Datatype                   |
|----------------------------|----------------------------|
| <i>Case ID column name</i> | Type of the case ID        |
| <code>PREDICTION</code>    | Type of the target         |
| <code>PROBABILITY</code>   | <code>BINARY_DOUBLE</code> |

### Anomaly Detection

The results table for Anomaly Detection has the columns described in [Table 48-42](#).

**Table 48-42 APPLY Results Table for Anomaly Detection**

| Column Name                | Datatype                   |
|----------------------------|----------------------------|
| <i>Case ID column name</i> | Type of the case ID        |
| <code>PREDICTION</code>    | <code>NUMBER</code>        |
| <code>PROBABILITY</code>   | <code>BINARY_DOUBLE</code> |

### Regression

The results table for Regression has the columns described in [APPLY Procedure](#).

**Table 48-43 APPLY Results Table for Regression**

| Column Name                | Datatype            |
|----------------------------|---------------------|
| <i>Case ID column name</i> | Type of the case ID |
| PREDICTION                 | Type of the target  |

**Clustering**

Clustering is an unsupervised mining function, and hence there are no targets. The results of an `APPLY` procedure will contain simply the cluster identifier corresponding to a case, and the associated probability. The results table has the columns described in [Table 48-44](#).

**Table 48-44 APPLY Results Table for Clustering**

| Column Name                | Datatype            |
|----------------------------|---------------------|
| <i>Case ID column name</i> | Type of the case ID |
| CLUSTER_ID                 | NUMBER              |
| PROBABILITY                | BINARY_DOUBLE       |

**Feature Extraction**

Feature Extraction is also an unsupervised mining function, and hence there are no targets. The results of an `APPLY` procedure will contain simply the feature identifier corresponding to a case, and the associated match quality. The results table has the columns described in [Table 48-45](#).

**Table 48-45 APPLY Results Table for Feature Extraction**

| Column Name                | Datatype            |
|----------------------------|---------------------|
| <i>Case ID column name</i> | Type of the case ID |
| FEATURE_ID                 | NUMBER              |
| MATCH_QUALITY              | BINARY_DOUBLE       |

**Examples**

This example applies the GLM Regression model `GLMR_SH_REGR_SAMPLE` to the data in the `MINING_DATA_APPLY_V` view. The `APPLY` results are output of the table `REGRESSION_APPLY_RESULT`.

```
SQL> BEGIN
      DBMS_DATA_MINING.APPLY (
        model_name      => 'glmr_sh_regr_sample',
        data_table_name => 'mining_data_apply_v',
        case_id_column_name => 'cust_id',
        result_table_name => 'regression_apply_result');
      END;
      /

SQL> SELECT * FROM regression_apply_result WHERE cust_id > 101485;

      CUST_ID PREDICTION
      -----
```

```
101486 22.8048824
101487 25.0261101
101488 48.6146619
101489 51.82595
101490 22.6220714
101491 61.3856816
101492 24.1400748
101493 58.034631
101494 45.7253149
101495 26.9763318
101496 48.1433425
101497 32.0573434
101498 49.8965531
101499 56.270656

```

## 48.7.5 COMPUTE\_CONFUSION\_MATRIX Procedure

This procedure computes a confusion matrix, stores it in a table in the user's schema, and returns the model accuracy.

A confusion matrix is a test metric for classification models. It compares the predictions generated by the model with the actual target values in a set of test data. The confusion matrix lists the number of times each class was correctly predicted and the number of times it was predicted to be one of the other classes.

COMPUTE\_CONFUSION\_MATRIX accepts three input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing either probabilities or costs
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values
- (Optional) A cost matrix table with predefined columns. See the Usage Notes for the column requirements.

### Syntax

```
DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX (
    accuracy                OUT NUMBER,
    apply_result_table_name IN  VARCHAR2,
    target_table_name       IN  VARCHAR2,
```

```

case_id_column_name      IN  VARCHAR2,
target_column_name       IN  VARCHAR2,
confusion_matrix_table_name IN  VARCHAR2,
score_column_name        IN  VARCHAR2 DEFAULT 'PREDICTION',
score_criterion_column_name IN  VARCHAR2 DEFAULT 'PROBABILITY',
cost_matrix_table_name   IN  VARCHAR2 DEFAULT NULL,
apply_result_schema_name IN  VARCHAR2 DEFAULT NULL,
target_schema_name       IN  VARCHAR2 DEFAULT NULL,
cost_matrix_schema_name  IN  VARCHAR2 DEFAULT NULL,
score_criterion_type     IN  VARCHAR2 DEFAULT 'PROBABILITY');

```

## Parameters

**Table 48-46 COMPUTE\_CONFUSION\_MATRIX Procedure Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| accuracy                    | Output parameter containing the overall percentage accuracy of the predictions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| apply_result_table_name     | Table containing the predictions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| target_table_name           | Table containing the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| case_id_column_name         | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| target_column_name          | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| confusion_matrix_table_name | Table containing the confusion matrix. The table will be created by the procedure in the user's schema.<br><br>The columns in the confusion matrix table are described in the Usage Notes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| score_column_name           | Column containing the predictions in the apply results table.<br>The default column name is <code>PREDICTION</code> , which is the default name created by the <code>APPLY</code> procedure (See " <a href="#">APPLY Procedure</a> ").                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| score_criterion_column_name | Column containing the scoring criterion in the apply results table. Contains either the probabilities or the costs that determine the predictions.<br><br>By default, scoring is based on probability; the class with the highest probability is predicted for each case. If scoring is based on cost, the class with the lowest cost is predicted.<br><br>The <code>score_criterion_type</code> parameter indicates whether probabilities or costs will be used for scoring.<br><br>The default column name is <code>'PROBABILITY'</code> , which is the default name created by the <code>APPLY</code> procedure (See " <a href="#">APPLY Procedure</a> ").<br><br>See the Usage Notes for additional information. |
| cost_matrix_table_name      | (Optional) Table that defines the costs associated with misclassifications. If a cost matrix table is provided and the <code>score_criterion_type</code> parameter is set to <code>'COSTS'</code> , the costs in this table will be used as the scoring criteria.<br><br>The columns in a cost matrix table are described in the Usage Notes.                                                                                                                                                                                                                                                                                                                                                                        |
| apply_result_schema_name    | Schema of the apply results table.<br>If null, the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 48-46 (Cont.) COMPUTE\_CONFUSION\_MATRIX Procedure Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| target_schema_name      | Schema of the table containing the known targets.<br>If null, the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| cost_matrix_schema_name | Schema of the cost matrix table, if one is provided.<br>If null, the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| score_criterion_type    | Whether to use probabilities or costs as the scoring criterion. Probabilities or costs are passed in the column identified in the score_criterion_column_name parameter.<br>The default value of score_criterion_type is 'PROBABILITY'. To use costs as the scoring criterion, specify 'COST'.<br>If score_criterion_type is set to 'COST' but no cost matrix is provided and if there is a scoring cost matrix associated with the model, then the associated costs are used for scoring.<br>See the Usage Notes and the Examples. |

#### Usage Notes

- The predictive information you pass to COMPUTE\_CONFUSION\_MATRIX may be generated using SQL PREDICTION functions, the DBMS\_DATA\_MINING.APPLY procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the confusion matrix.
- Instead of passing a cost matrix to COMPUTE\_CONFUSION\_MATRIX, you can use a scoring cost matrix associated with the model. A scoring cost matrix can be embedded in the model or it can be defined dynamically when the model is applied. To use a scoring cost matrix, invoke the SQL PREDICTION\_COST function to populate the score criterion column.
- The predictions that you pass to COMPUTE\_CONFUSION\_MATRIX are in a table or view specified in apply\_result\_table\_name.

```
CREATE TABLE apply_result_table_name AS (
    case_id_column_name          VARCHAR2,
    score_column_name            VARCHAR2,
    score_criterion_column_name  VARCHAR2);
```

- A cost matrix must have the columns described in [Table 48-47](#).

**Table 48-47 Columns in a Cost Matrix**

| Column Name            | Datatype                                                                                                                                                                                                |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actual_target_value    | Type of the target column in the build data                                                                                                                                                             |
| predicted_target_value | Type of the predicted target in the test data. The type of the predicted target must be the same as the type of the actual target unless the predicted target has an associated reverse transformation. |
| cost                   | BINARY_DOUBLE                                                                                                                                                                                           |

## Examples

These examples use the Naive Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

### Compute a Confusion Matrix Based on Probabilities

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id,
         PREDICTION(nb_sh_clas_sample USING *) prediction,
         PREDICTION_PROBABILITY(nb_sh_clas_sample USING *) probability
  FROM mining_data_test_v;
```

Using probabilities as the scoring criterion, you can compute the confusion matrix as follows.

```
DECLARE
  v_accuracy    NUMBER;
BEGIN
  DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX (
    accuracy              => v_accuracy,
    apply_result_table_name => 'nb_apply_results',
    target_table_name     => 'mining_data_test_v',
    case_id_column_name   => 'cust_id',
    target_column_name    => 'affinity_card',
    confusion_matrix_table_name => 'nb_confusion_matrix',
    score_column_name     => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY'
    cost_matrix_table_name => null,
    apply_result_schema_name => null,
```

```

        target_schema_name      => null,
        cost_matrix_schema_name => null,
        score_criterion_type    => 'PROBABILITY';
    DBMS_OUTPUT.PUT_LINE('**** MODEL ACCURACY ****: ' || ROUND(v_accuracy,4));
END;
/

```

The confusion matrix and model accuracy are shown as follows.

```
**** MODEL ACCURACY ****: .7847
```

```
SQL>SELECT * from nb_confusion_matrix;
```

| ACTUAL_TARGET_VALUE | PREDICTED_TARGET_VALUE | VALUE |
|---------------------|------------------------|-------|
| 1                   | 0                      | 60    |
| 0                   | 0                      | 891   |
| 1                   | 1                      | 286   |
| 0                   | 1                      | 263   |

### Compute a Confusion Matrix Based on a Cost Matrix Table

The confusion matrix in the previous example shows a high rate of false positives. For 263 cases, the model predicted 1 when the actual value was 0. You could use a cost matrix to minimize this type of error.

The cost matrix table `nb_cost_matrix` specifies that a false positive is 3 times more costly than a false negative.

```
SQL> SELECT * from nb_cost_matrix;
```

| ACTUAL_TARGET_VALUE | PREDICTED_TARGET_VALUE | COST |
|---------------------|------------------------|------|
| 0                   | 0                      | 0    |
| 0                   | 1                      | .75  |
| 1                   | 0                      | .25  |
| 1                   | 1                      | 0    |

This statement shows how to generate the predictions using `APPLY`.

```

BEGIN
    DBMS_DATA_MINING.APPLY(
        model_name      => 'nb_sh_clas_sample',
        data_table_name => 'mining_data_test_v',
        case_id_column_name => 'cust_id',
        result_table_name => 'nb_apply_results');
END;
/

```

This statement computes the confusion matrix using the cost matrix table. The score criterion column is named 'PROBABILITY', which is the name generated by `APPLY`.

```

DECLARE
    v_accuracy    NUMBER;
BEGIN
    DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX (
        accuracy              => v_accuracy,
        apply_result_table_name => 'nb_apply_results',
        target_table_name     => 'mining_data_test_v',
        case_id_column_name   => 'cust_id',
        target_column_name    => 'affinity_card',
        confusion_matrix_table_name => 'nb_confusion_matrix',
        score_column_name     => 'PREDICTION',
        score_criterion_column_name => 'PROBABILITY',
        cost_matrix_table_name => 'nb_cost_matrix',

```

```

        apply_result_schema_name      => null,
        target_schema_name            => null,
        cost_matrix_schema_name       => null,
        score_criterion_type          => 'COST');
    DBMS_OUTPUT.PUT_LINE('**** MODEL ACCURACY ****: ' || ROUND(v_accuracy,4));
END;
/

```

The resulting confusion matrix shows a decrease in false positives (212 instead of 263).

```
**** MODEL ACCURACY ****: .798
```

```
SQL> SELECT * FROM nb_confusion_matrix;
```

| ACTUAL_TARGET_VALUE | PREDICTED_TARGET_VALUE | VALUE |
|---------------------|------------------------|-------|
| 1                   | 0                      | 91    |
| 0                   | 0                      | 942   |
| 1                   | 1                      | 255   |
| 0                   | 1                      | 212   |

### Compute a Confusion Matrix Based on Embedded Costs

You can use the `ADD_COST_MATRIX` procedure to embed a cost matrix in a model. The embedded costs can be used instead of probabilities for scoring. This statement adds the previously-defined cost matrix to the model.

```
BEGIN    DBMS_DATA_MINING.ADD_COST_MATRIX ('nb_sh_clas_sample', 'nb_cost_matrix');END;/
```

The following statement applies the model to the test data using the embedded costs and stores the results in a table.

```
CREATE TABLE nb_apply_results AS
    SELECT cust_id,
           PREDICTION(nb_sh_clas_sample COST MODEL USING *) prediction,
           PREDICTION_COST(nb_sh_clas_sample COST MODEL USING *) cost
    FROM mining_data_test_v;
```

You can compute the confusion matrix using the embedded costs.

```
DECLARE
    v_accuracy          NUMBER;
BEGIN
    DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX (
        accuracy          => v_accuracy,
        apply_result_table_name => 'nb_apply_results',
        target_table_name  => 'mining_data_test_v',
        case_id_column_name => 'cust_id',
        target_column_name  => 'affinity_card',
        confusion_matrix_table_name => 'nb_confusion_matrix',
        score_column_name   => 'PREDICTION',
        score_criterion_column_name => 'COST',
        cost_matrix_table_name => null,
        apply_result_schema_name => null,
        target_schema_name   => null,
        cost_matrix_schema_name => null,
        score_criterion_type  => 'COST');
END;
/

```

The results are:

```
**** MODEL ACCURACY ****: .798
```

```
SQL> SELECT * FROM nb_confusion_matrix;
ACTUAL_TARGET_VALUE PREDICTED_TARGET_VALUE  VALUE
-----
                1                0         91
                0                0        942
                1                1        255
                0                1        212
```

## 48.7.6 COMPUTE\_CONFUSION\_MATRIX\_PART Procedure

The `COMPUTE_CONFUSION_MATRIX_PART` procedure computes a confusion matrix, stores it in a table in the user's schema, and returns the model accuracy.

`COMPUTE_CONFUSION_MATRIX_PART` provides support to computation of evaluation metrics per-partition for partitioned models. For non-partitioned models, refer to [COMPUTE\\_CONFUSION\\_MATRIX Procedure](#).

A confusion matrix is a test metric for Classification models. It compares the predictions generated by the model with the actual target values in a set of test data. The confusion matrix lists the number of times each class was correctly predicted and the number of times it was predicted to be one of the other classes.

`COMPUTE_CONFUSION_MATRIX_PART` accepts three input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing either probabilities or costs
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values
- (Optional) A cost matrix table with predefined columns. See the Usage Notes for the column requirements.

| accuracy                    | Output parameter containing the overall percentage accuracy of the predictions<br><br>The output argument is changed from NUMBER to DM_NESTED_NUMERICALS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| apply_result_table_name     | Table containing the predictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| target_table_name           | Table containing the known target values from the test data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| case_id_column_name         | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| target_column_name          | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| confusion_matrix_table_name | Table containing the confusion matrix. The table will be created by the procedure in the user's schema.<br><br>The columns in the confusion matrix table are described in the Usage Notes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| score_column_name           | Column containing the predictions in the apply results table.<br><br>The default column name is PREDICTION, which is the default name created by the APPLY procedure (See " <a href="#">APPLY Procedure</a> ").                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| score_criterion_column_name | Column containing the scoring criterion in the apply results table. Contains either the probabilities or the costs that determine the predictions.<br><br>By default, scoring is based on probability; the class with the highest probability is predicted for each case. If scoring is based on cost, then the class with the lowest cost is predicted.<br><br>The score_criterion_type parameter indicates whether probabilities or costs will be used for scoring.<br><br>The default column name is PROBABILITY, which is the default name created by the APPLY procedure (See " <a href="#">APPLY Procedure</a> ").<br><br>See the Usage Notes for additional information. |
| score_partition_column_name | (Optional) Parameter indicating the column which contains the name of the partition. This column slices the input test results such that each partition has independent evaluation matrices computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 48-49 (Cont.) COMPUTE\_CONFUSION\_MATRIX\_PART Procedure Parameters**

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cost_matrix_table_name</code>   | (Optional) Table that defines the costs associated with misclassifications. If a cost matrix table is provided and the <code>score_criterion_type</code> parameter is set to <code>COSTS</code> , the costs in this table will be used as the scoring criteria.<br>The columns in a cost matrix table are described in the Usage Notes.                                                                                                                                                                                                                                                                       |
| <code>apply_result_schema_name</code> | Schema of the apply results table.<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>target_schema_name</code>       | Schema of the table containing the known targets.<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>cost_matrix_schema_name</code>  | Schema of the cost matrix table, if one is provided.<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>score_criterion_type</code>     | Whether to use probabilities or costs as the scoring criterion. Probabilities or costs are passed in the column identified in the <code>score_criterion_column_name</code> parameter.<br>The default value of <code>score_criterion_type</code> is <code>PROBABILITY</code> . To use costs as the scoring criterion, specify <code>COST</code> .<br>If <code>score_criterion_type</code> is set to <code>COST</code> but no cost matrix is provided and if there is a scoring cost matrix associated with the model, then the associated costs are used for scoring.<br>See the Usage Notes and the Examples. |

### Usage Notes

- The predictive information you pass to `COMPUTE_CONFUSION_MATRIX_PART` may be generated using SQL `PREDICTION` functions, the `DBMS_DATA_MINING.APPLY` procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the confusion matrix.
- Instead of passing a cost matrix to `COMPUTE_CONFUSION_MATRIX_PART`, you can use a scoring cost matrix associated with the model. A scoring cost matrix can be embedded in the model or it can be defined dynamically when the model is applied. To use a scoring cost matrix, invoke the `SQL_PREDICTION_COST` function to populate the score criterion column.
- The predictions that you pass to `COMPUTE_CONFUSION_MATRIX_PART` are in a table or view specified in `apply_result_table_name`.

```
CREATE TABLE apply_result_table_name AS (
    case_id_column_name          VARCHAR2,
    score_column_name            VARCHAR2,
    score_criterion_column_name  VARCHAR2);
```

- A cost matrix must have the columns described in [Table 48-47](#).

**Table 48-50 Columns in a Cost Matrix**

| Column Name            | Datatype                                                                                                                                                                                                |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actual_target_value    | Type of the target column in the test data                                                                                                                                                              |
| predicted_target_value | Type of the predicted target in the test data. The type of the predicted target must be the same as the type of the actual target unless the predicted target has an associated reverse transformation. |
| cost                   | BINARY_DOUBLE                                                                                                                                                                                           |

 **See Also:***Oracle Data Mining User's Guide* for valid target datatypes*Oracle Data Mining Concepts* for more information about cost matrixes

- The confusion matrix created by `COMPUTE_CONFUSION_MATRIX_PART` has the columns described in [Table 48-48](#).

**Table 48-51 Columns in a Confusion Matrix Part**

| Column Name            | Datatype                                                                                                                                                                                           |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actual_target_value    | Type of the target column in the test data                                                                                                                                                         |
| predicted_target_value | Type of the predicted target in the test data. The type of the predicted target is the same as the type of the actual target unless the predicted target has an associated reverse transformation. |
| value                  | BINARY_DOUBLE                                                                                                                                                                                      |

 **See Also:***Oracle Data Mining Concepts* for more information about confusion matrixes**Examples**

These examples use the Naïve Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

**Compute a Confusion Matrix Based on Probabilities**

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id,
         PREDICTION(nb_sh_clas_sample USING *) prediction,
         PREDICTION_PROBABILITY(nb_sh_clas_sample USING *) probability
  FROM mining_data_test_v;
```

Using probabilities as the scoring criterion, you can compute the confusion matrix as follows.

```
DECLARE
  v_accuracy    NUMBER;
```

```
BEGIN
  DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX_PART (
    accuracy                => v_accuracy,
    apply_result_table_name => 'nb_apply_results',
    target_table_name       => 'mining_data_test_v',
    case_id_column_name     => 'cust_id',
    target_column_name      => 'affinity_card',
    confusion_matrix_table_name => 'nb_confusion_matrix',
    score_column_name       => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY',
    score_partition_column_name => 'PARTITION_NAME',
    cost_matrix_table_name  => null,
    apply_result_schema_name => null,
    target_schema_name      => null,
    cost_matrix_schema_name => null,
    score_criterion_type    => 'PROBABILITY');
  DBMS_OUTPUT.PUT_LINE('**** MODEL ACCURACY ****: ' || ROUND(v_accuracy,4));
END;
/
```

The confusion matrix and model accuracy are shown as follows.

```
**** MODEL ACCURACY ****: .7847
```

```
SELECT * FROM NB_CONFUSION_MATRIX;
ACTUAL_TARGET_VALUE PREDICTED_TARGET_VALUE    VALUE
-----
                1                0            60
                0                0           891
                1                1           286
                0                1           263
```

### Compute a Confusion Matrix Based on a Cost Matrix Table

The confusion matrix in the previous example shows a high rate of false positives. For 263 cases, the model predicted 1 when the actual value was 0. You could use a cost matrix to minimize this type of error.

The cost matrix table `nb_cost_matrix` specifies that a false positive is 3 times more costly than a false negative.

```
SELECT * from NB_COST_MATRIX;
ACTUAL_TARGET_VALUE PREDICTED_TARGET_VALUE    COST
-----
                0                0            0
                0                1           .75
                1                0           .25
                1                1            0
```

This statement shows how to generate the predictions using `APPLY`.

```
BEGIN
  DBMS_DATA_MINING.APPLY(
    model_name              => 'nb_sh_clas_sample',
    data_table_name         => 'mining_data_test_v',
    case_id_column_name     => 'cust_id',
    result_table_name       => 'nb_apply_results');
END;
/
```

This statement computes the confusion matrix using the cost matrix table. The score criterion column is named 'PROBABILITY', which is the name generated by `APPLY`.

```

DECLARE
  v_accuracy    NUMBER;
BEGIN
  DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX_PART (
    accuracy              => v_accuracy,
    apply_result_table_name => 'nb_apply_results',
    target_table_name      => 'mining_data_test_v',
    case_id_column_name    => 'cust_id',
    target_column_name     => 'affinity_card',
    confusion_matrix_table_name => 'nb_confusion_matrix',
    score_column_name      => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY',
    score_partition_column_name => 'PARTITION_NAME',
    cost_matrix_table_name => 'nb_cost_matrix',
    apply_result_schema_name => null,
    target_schema_name     => null,
    cost_matrix_schema_name => null,
    score_criterion_type   => 'COST');
  DBMS_OUTPUT.PUT_LINE('**** MODEL ACCURACY ****: ' || ROUND(v_accuracy,4));
END;
/

```

The resulting confusion matrix shows a decrease in false positives (212 instead of 263).

```
**** MODEL ACCURACY ****: .798
```

```

SELECT * FROM NB_CONFUSION_MATRIX;

```

| ACTUAL_TARGET_VALUE | PREDICTED_TARGET_VALUE | VALUE |
|---------------------|------------------------|-------|
| 1                   | 0                      | 91    |
| 0                   | 0                      | 942   |
| 1                   | 1                      | 255   |
| 0                   | 1                      | 212   |

### Compute a Confusion Matrix Based on Embedded Costs

You can use the `ADD_COST_MATRIX` procedure to embed a cost matrix in a model. The embedded costs can be used instead of probabilities for scoring. This statement adds the previously-defined cost matrix to the model.

```

BEGIN
  DBMS_DATA_MINING.ADD_COST_MATRIX ('nb_sh_clas_sample', 'nb_cost_matrix');
END;/

```

The following statement applies the model to the test data using the embedded costs and stores the results in a table.

```

CREATE TABLE nb_apply_results AS
  SELECT cust_id,
         PREDICTION(nb_sh_clas_sample COST MODEL USING *) prediction,
         PREDICTION_COST(nb_sh_clas_sample COST MODEL USING *) cost
  FROM mining_data_test_v;

```

You can compute the confusion matrix using the embedded costs.

```

DECLARE
  v_accuracy    NUMBER;
BEGIN
  DBMS_DATA_MINING.COMPUTE_CONFUSION_MATRIX_PART (
    accuracy              => v_accuracy,
    apply_result_table_name => 'nb_apply_results',
    target_table_name      => 'mining_data_test_v',
    case_id_column_name    => 'cust_id',

```

```

target_column_name      => 'affinity_card',
confusion_matrix_table_name => 'nb_confusion_matrix',
score_column_name       => 'PREDICTION',
score_criterion_column_name => 'COST',
score_partition_column_name => 'PARTITION_NAME'
cost_matrix_table_name   => null,
apply_result_schema_name => null,
target_schema_name       => null,
cost_matrix_schema_name  => null,
score_criterion_type     => 'COST');

END;
/

```

The results are:

```
**** MODEL ACCURACY ****: .798
```

```

SELECT * FROM NB_CONFUSION_MATRIX;

```

| ACTUAL_TARGET_VALUE | PREDICTED_TARGET_VALUE | VALUE |
|---------------------|------------------------|-------|
| 1                   | 0                      | 91    |
| 0                   | 0                      | 942   |
| 1                   | 1                      | 255   |
| 0                   | 1                      | 212   |

## 48.7.7 COMPUTE\_LIFT Procedure

This procedure computes lift and stores the results in a table in the user's schema.

Lift is a test metric for binary classification models. To compute lift, one of the target values must be designated as the positive class. `COMPUTE_LIFT` compares the predictions generated by the model with the actual target values in a set of test data. Lift measures the degree to which the model's predictions of the positive class are an improvement over random chance.

Lift is computed on scoring results that have been ranked by probability (or cost) and divided into quantiles. Each quantile includes the scores for the same number of cases.

`COMPUTE_LIFT` calculates quantile-based and cumulative statistics. The number of quantiles and the positive class are user-specified. Additionally, `COMPUTE_LIFT` accepts three input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing either probabilities or costs associated with the predictions
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values
- (Optional) A cost matrix table with predefined columns. See the Usage Notes for the column requirements.

## Parameters

**Table 48-52 COMPUTE\_LIFT Procedure Parameters**

| Parameter                            | Description                                                                                                                                                                                                                          |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apply_result_table_name</code> | Table containing the predictions.                                                                                                                                                                                                    |
| <code>target_table_name</code>       | Table containing the known target values from the test data.                                                                                                                                                                         |
| <code>case_id_column_name</code>     | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                      |
| <code>target_column_name</code>      | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                             |
| <code>lift_table_name</code>         | Table containing the lift statistics. The table will be created by the procedure in the user's schema.<br>The columns in the lift table are described in the Usage Notes.                                                            |
| <code>positive_target_value</code>   | The positive class. This should be the class of interest, for which you want to calculate lift.<br>If the target column is a <code>NUMBER</code> , you can use the <code>TO_CHAR()</code> operator to provide the value as a string. |
| <code>score_column_name</code>       | Column containing the predictions in the apply results table.<br>The default column name is 'PREDICTION', which is the default name created by the <code>APPLY</code> procedure (See <a href="#">"APPLY Procedure"</a> ).            |

**Table 48-52 (Cont.) COMPUTE\_LIFT Procedure Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| score_criterion_column_name | <p>Column containing the scoring criterion in the apply results table. Contains either the probabilities or the costs that determine the predictions.</p> <p>By default, scoring is based on probability; the class with the highest probability is predicted for each case. If scoring is based on cost, the class with the lowest cost is predicted.</p> <p>The <code>score_criterion_type</code> parameter indicates whether probabilities or costs will be used for scoring.</p> <p>The default column name is 'PROBABILITY', which is the default name created by the <code>APPLY</code> procedure (See "<a href="#">APPLY Procedure</a>").</p> <p>See the Usage Notes for additional information.</p> |
| num_quantiles               | <p>Number of quantiles to be used in calculating lift. The default is 10.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| cost_matrix_table_name      | <p>(Optional) Table that defines the costs associated with misclassifications. If a cost matrix table is provided and the <code>score_criterion_type</code> parameter is set to 'COST', the costs will be used as the scoring criteria.</p> <p>The columns in a cost matrix table are described in the Usage Notes.</p>                                                                                                                                                                                                                                                                                                                                                                                     |
| apply_result_schema_name    | <p>Schema of the apply results table.</p> <p>If null, the user's schema is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| target_schema_name          | <p>Schema of the table containing the known targets.</p> <p>If null, the user's schema is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| cost_matrix_schema_name     | <p>Schema of the cost matrix table, if one is provided.</p> <p>If null, the user's schema is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| score_criterion_type        | <p>Whether to use probabilities or costs as the scoring criterion. Probabilities or costs are passed in the column identified in the <code>score_criterion_column_name</code> parameter.</p> <p>The default value of <code>score_criterion_type</code> is 'PROBABILITY'. To use costs as the scoring criterion, specify 'COST'.</p> <p>If <code>score_criterion_type</code> is set to 'COST' but no cost matrix is provided and if there is a scoring cost matrix associated with the model, then the associated costs are used for scoring.</p> <p>See the Usage Notes and the Examples.</p>                                                                                                               |

### Usage Notes

- The predictive information you pass to `COMPUTE_LIFT` may be generated using SQL `PREDICTION` functions, the `DBMS_DATA_MINING.APPLY` procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the lift.
- Instead of passing a cost matrix to `COMPUTE_LIFT`, you can use a scoring cost matrix associated with the model. A scoring cost matrix can be embedded in the model or it can be defined dynamically when the model is applied. To use a scoring cost matrix, invoke the `SQL_PREDICTION_COST` function to populate the score criterion column.

- The predictions that you pass to `COMPUTE_LIFT` are in a table or view specified in `apply_results_table_name`.

```
CREATE TABLE apply_result_table_name AS (
    case_id_column_name          VARCHAR2,
    score_column_name            VARCHAR2,
    score_criterion_column_name  VARCHAR2);
```

- A cost matrix must have the columns described in [Table 48-53](#).

**Table 48-53 Columns in a Cost Matrix**

| Column Name            | Datatype                                                                                                                                                                                                |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actual_target_value    | Type of the target column in the build data                                                                                                                                                             |
| predicted_target_value | Type of the predicted target in the test data. The type of the predicted target must be the same as the type of the actual target unless the predicted target has an associated reverse transformation. |
| cost                   | NUMBER                                                                                                                                                                                                  |

*Oracle Data Mining Concepts* for details about the information in the lift table

- When a cost matrix is passed to `COMPUTE_LIFT`, the cost threshold is returned in the `probability_threshold` column of the lift table.

### Examples

This example uses the Naive Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

The example illustrates lift based on probabilities. For examples that show computation based on costs, see "[COMPUTE\\_CONFUSION\\_MATRIX Procedure](#)".

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id, t.prediction, t.probability
  FROM mining_data_test_v, TABLE(PREDICTION_SET(nb_sh_clas_sample USING *)) t;
```

Using probabilities as the scoring criterion, you can compute lift as follows.

```
BEGIN
  DBMS_DATA_MINING.COMPUTE_LIFT (
    apply_result_table_name => 'nb_apply_results',
    target_table_name      => 'mining_data_test_v',
    case_id_column_name    => 'cust_id',
    target_column_name     => 'affinity_card',
    lift_table_name        => 'nb_lift',
    positive_target_value  => to_char(1),
    score_column_name      => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY',
    num_quantiles          => 10,
    cost_matrix_table_name => null,
    apply_result_schema_name => null,
    target_schema_name     => null,
    cost_matrix_schema_name => null,
    score_criterion_type   => 'PROBABILITY');
END;
/
```

This query displays some of the statistics from the resulting lift table.

```
SQL>SELECT quantile_number, probability_threshold, gain_cumulative,
  quantile_total_count
  FROM nb_lift;
```

| QUANTILE_NUMBER | PROBABILITY_THRESHOLD | GAIN_CUMULATIVE | QUANTILE_TOTAL_COUNT |
|-----------------|-----------------------|-----------------|----------------------|
| 1               | .989335775            | .15034965       | 55                   |
| 2               | .980534911            | .26048951       | 55                   |

| 7               | .904403627            | .748251748      | 55                   |
| 8               | .836482525            | .839160839      | 55                   |
| 10              | .500184953            | 1               | 54                   |

## 48.7.8 COMPUTE\_LIFT\_PART Procedure

The `COMPUTE_LIFT_PART` procedure computes Lift and stores the results in a table in the user's schema. This procedure provides support to the computation of evaluation metrics per-partition for partitioned models.

Lift is a test metric for binary Classification models. To compute Lift, one of the target values must be designated as the positive class. `COMPUTE_LIFT_PART` compares the predictions generated by the model with the actual target values in a set of test data. Lift measures the degree to which the model's predictions of the positive class are an improvement over random chance.

Lift is computed on scoring results that have been ranked by probability (or cost) and divided into quantiles. Each quantile includes the scores for the same number of cases.

`COMPUTE_LIFT_PART` calculates quantile-based and cumulative statistics. The number of quantiles and the positive class are user-specified. Additionally, `COMPUTE_LIFT_PART` accepts three input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing either probabilities or costs associated with the predictions
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values
- (Optional) A cost matrix table with predefined columns. See the Usage Notes for the column requirements.

### Syntax

```
DBMS_DATA_MINING.COMPUTE_LIFT_PART (
  apply_result_table_name      IN VARCHAR2,
  target_table_name            IN VARCHAR2,
  case_id_column_name          IN VARCHAR2,
  target_column_name           IN VARCHAR2,
```

```
lift_table_name          IN VARCHAR2,
positive_target_value    IN VARCHAR2,
score_column_name        IN VARCHAR2 DEFAULT 'PREDICTION',
score_criterion_column_name IN VARCHAR2 DEFAULT 'PROBABILITY',
score_partition_column_name IN VARCHAR2 DEFAULT 'PARTITION_NAME',
num_quantiles            IN NUMBER   DEFAULT 10,
cost_matrix_table_name   IN VARCHAR2 DEFAULT NULL,
apply_result_schema_name IN VARCHAR2 DEFAULT NULL,
target_schema_name       IN VARCHAR2 DEFAULT NULL,
cost_matrix_schema_name  IN VARCHAR2 DEFAULT NULL,
score_criterion_type     IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 48-55 COMPUTE\_LIFT\_PART Procedure Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apply_result_table_name     | Table containing the predictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| target_table_name           | Table containing the known target values from the test data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| case_id_column_name         | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| target_column_name          | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| lift_table_name             | Table containing the Lift statistics. The table will be created by the procedure in the user's schema.<br>The columns in the Lift table are described in the Usage Notes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| positive_target_value       | The positive class. This should be the class of interest, for which you want to calculate Lift.<br>If the target column is a NUMBER, then you can use the TO_CHAR() operator to provide the value as a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| score_column_name           | Column containing the predictions in the apply results table.<br>The default column name is PREDICTION, which is the default name created by the APPLY procedure (See " <a href="#">APPLY Procedure</a> ").                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| score_criterion_column_name | Column containing the scoring criterion in the apply results table. Contains either the probabilities or the costs that determine the predictions.<br>By default, scoring is based on probability; the class with the highest probability is predicted for each case. If scoring is based on cost, then the class with the lowest cost is predicted.<br>The score_criterion_type parameter indicates whether probabilities or costs will be used for scoring.<br>The default column name is PROBABILITY, which is the default name created by the APPLY procedure (See " <a href="#">APPLY Procedure</a> ").<br>See the Usage Notes for additional information. |
| score_partition_column_name | Optional parameter indicating the column containing the name of the partition. This column slices the input test results such that each partition has independent evaluation matrices computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 48-55 (Cont.) COMPUTE\_LIFT\_PART Procedure Parameters**

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num_quantiles            | Number of quantiles to be used in calculating Lift. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| cost_matrix_table_name   | (Optional) Table that defines the costs associated with misclassifications. If a cost matrix table is provided and the <code>score_criterion_type</code> parameter is set to <code>COST</code> , then the costs will be used as the scoring criteria.<br><br>The columns in a cost matrix table are described in the Usage Notes.                                                                                                                                                                                                                                                                                         |
| apply_result_schema_name | Schema of the apply results table<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| target_schema_name       | Schema of the table containing the known targets<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| cost_matrix_schema_name  | Schema of the cost matrix table, if one is provided<br>If null, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| score_criterion_type     | Whether to use probabilities or costs as the scoring criterion. Probabilities or costs are passed in the column identified in the <code>score_criterion_column_name</code> parameter.<br><br>The default value of <code>score_criterion_type</code> is <code>PROBABILITY</code> . To use costs as the scoring criterion, specify <code>COST</code> .<br><br>If <code>score_criterion_type</code> is set to <code>COST</code> but no cost matrix is provided and if there is a scoring cost matrix associated with the model, then the associated costs are used for scoring.<br><br>See the Usage Notes and the Examples. |

#### Usage Notes

- The predictive information you pass to `COMPUTE_LIFT_PART` may be generated using SQL `PREDICTION` functions, the `DBMS_DATA_MINING.APPLY` procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the Lift.
- Instead of passing a cost matrix to `COMPUTE_LIFT_PART`, you can use a scoring cost matrix associated with the model. A scoring cost matrix can be embedded in the model or it can be defined dynamically when the model is applied. To use a scoring cost matrix, invoke the SQL `PREDICTION_COST` function to populate the score criterion column.
- The predictions that you pass to `COMPUTE_LIFT_PART` are in a table or view specified in `apply_results_table_name`.

```
CREATE TABLE apply_result_table_name AS (
    case_id_column_name          VARCHAR2,
    score_column_name            VARCHAR2,
    score_criterion_column_name  VARCHAR2);
```

- A cost matrix must have the columns described in [Table 48-53](#).

**Table 48-56 Columns in a Cost Matrix**

| Column Name            | Datatype                                                                                                                                                                                                |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| actual_target_value    | Type of the target column in the test data                                                                                                                                                              |
| predicted_target_value | Type of the predicted target in the test data. The type of the predicted target must be the same as the type of the actual target unless the predicted target has an associated reverse transformation. |
| cost                   | NUMBER                                                                                                                                                                                                  |

- The table created by `COMPUTE_LIFT_PART` has the columns described in [Table 48-54](#)

**Table 48-57 Columns in a COMPUTE\_LIFT\_PART Table**

| Column Name                | Datatype |
|----------------------------|----------|
| quantile_number            | NUMBER   |
| probability_threshold      | NUMBER   |
| gain_cumulative            | NUMBER   |
| quantile_total_count       | NUMBER   |
| quantile_target_count      | NUMBER   |
| percent_records_cumulative | NUMBER   |
| lift_cumulative            | NUMBER   |
| target_density_cumulative  | NUMBER   |
| targets_cumulative         | NUMBER   |
| non_targets_cumulative     | NUMBER   |
| lift_quantile              | NUMBER   |
| target_density             | NUMBER   |

 **See Also:**

*Oracle Data Mining Concepts* for details about the information in the Lift table

- When a cost matrix is passed to `COMPUTE_LIFT_PART`, the cost threshold is returned in the `probability_threshold` column of the Lift table.

**Examples**

This example uses the Naive Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

The example illustrates Lift based on probabilities. For examples that show computation based on costs, see "[COMPUTE\\_CONFUSION\\_MATRIX Procedure](#)".

For a partitioned model example, see "[COMPUTE\\_CONFUSION\\_MATRIX\\_PART Procedure](#)".

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id, t.prediction, t.probability
  FROM mining_data_test_v, TABLE(PREDICTION_SET(nb_sh_clas_sample USING *)) t;
```

Using probabilities as the scoring criterion, you can compute Lift as follows.

```
BEGIN
  DBMS_DATA_MINING.COMPUTE_LIFT_PART (
    apply_result_table_name => 'nb_apply_results',
    target_table_name       => 'mining_data_test_v',
    case_id_column_name     => 'cust_id',
    target_column_name      => 'affinity_card',
    lift_table_name         => 'nb_lift',
    positive_target_value   => to_char(1),
    score_column_name       => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY',
    score_partition_column_name => 'PARTITION_NAME',
    num_quantiles           => 10,
    cost_matrix_table_name  => null,
    apply_result_schema_name => null,
    target_schema_name      => null,
    cost_matrix_schema_name => null,
    score_criterion_type    => 'PROBABILITY');
END;
/
```

This query displays some of the statistics from the resulting Lift table.

```
SELECT quantile_number, probability_threshold, gain_cumulative,
       quantile_total_count
FROM nb_lift;
```

| QUANTILE_NUMBER | PROBABILITY_THRESHOLD | GAIN_CUMULATIVE | QUANTILE_TOTAL_COUNT |
|-----------------|-----------------------|-----------------|----------------------|
| 1               | .989335775            | .15034965       | 55                   |
| 2               | .980534911            | .26048951       | 55                   |
| 3               | .968506098            | .374125874      | 55                   |

| 6               | .927454174            | .66958042       | 55                   |
| 7               | .904403627            | .748251748      | 55                   |
| 8               | .836482525            | .839160839      | 55                   |
| 10              | .500184953            | 1               | 54                   |

## 48.7.9 COMPUTE\_ROC Procedure

This procedure computes the receiver operating characteristic (ROC), stores the results in a table in the user's schema, and returns a measure of the model accuracy.

ROC is a test metric for binary classification models. To compute ROC, one of the target values must be designated as the positive class. `COMPUTE_ROC` compares the predictions generated by the model with the actual target values in a set of test data.

ROC measures the impact of changes in the probability threshold. The probability threshold is the decision point used by the model for predictions. In binary classification, the default probability threshold is 0.5. The value predicted for each case is the one with a probability greater than 50%.

ROC can be plotted as a curve on an X-Y axis. The false positive rate is placed on the X axis. The true positive rate is placed on the Y axis. A false positive is a positive prediction for a case that is negative in the test data. A true positive is a positive prediction for a case that is positive in the test data.

COMPUTE\_ROC accepts two input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing probabilities
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values

## Syntax

```
DBMS_DATA_MINING.COMPUTE_ROC (
    roc_area_under_curve          OUT NUMBER,
    apply_result_table_name       IN  VARCHAR2,
    target_table_name             IN  VARCHAR2,
    case_id_column_name           IN  VARCHAR2,
    target_column_name            IN  VARCHAR2,
    roc_table_name                IN  VARCHAR2,
    positive_target_value         IN  VARCHAR2,
    score_column_name             IN  VARCHAR2 DEFAULT 'PREDICTION',
    score_criterion_column_name   IN  VARCHAR2 DEFAULT 'PROBABILITY',
    apply_result_schema_name      IN  VARCHAR2 DEFAULT NULL,
    target_schema_name            IN  VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 48-58 COMPUTE\_ROC Procedure Parameters**

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>roc_area_under_the_curve</code>    | Output parameter containing the area under the ROC curve (AUC). The AUC measures the likelihood that an actual positive will be predicted as positive.<br><br>The greater the AUC, the greater the flexibility of the model in accommodating trade-offs between positive and negative class predictions. AUC can be especially important when one target class is rarer or more important to identify than another. |
| <code>apply_result_table_name</code>     | Table containing the predictions.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>target_table_name</code>           | Table containing the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                        |
| <code>case_id_column_name</code>         | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                                                                                                                                                                                                     |
| <code>target_column_name</code>          | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                                                                                                                                                                                                            |
| <code>roc_table_name</code>              | Table containing the ROC output. The table will be created by the procedure in the user's schema.<br><br>The columns in the ROC table are described in the Usage Notes.                                                                                                                                                                                                                                             |
| <code>positive_target_value</code>       | The positive class. This should be the class of interest, for which you want to calculate ROC.<br><br>If the target column is a <code>NUMBER</code> , you can use the <code>TO_CHAR()</code> operator to provide the value as a string.                                                                                                                                                                             |
| <code>score_column_name</code>           | Column containing the predictions in the apply results table.<br>The default column name is 'PREDICTION', which is the default name created by the <code>APPLY</code> procedure (See " <a href="#">APPLY Procedure</a> ").                                                                                                                                                                                          |
| <code>score_criterion_column_name</code> | Column containing the scoring criterion in the apply results table. Contains the probabilities that determine the predictions.<br><br>The default column name is 'PROBABILITY', which is the default name created by the <code>APPLY</code> procedure (See " <a href="#">APPLY Procedure</a> ").                                                                                                                    |
| <code>apply_result_schema_name</code>    | Schema of the apply results table.<br>If null, the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                        |
| <code>target_schema_name</code>          | Schema of the table containing the known targets.<br>If null, the user's schema is assumed.                                                                                                                                                                                                                                                                                                                         |

## Usage Notes

- The predictive information you pass to `COMPUTE_ROC` may be generated using SQL `PREDICTION` functions, the `DBMS_DATA_MINING.APPLY` procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the receiver operating characteristic.
- The predictions that you pass to `COMPUTE_ROC` are in a table or view specified in `apply_results_table_name`.

```
CREATE TABLE apply_result_table_name AS (
    case_id_column_name          VARCHAR2,
    score_column_name            VARCHAR2,
    score_criterion_column_name  VARCHAR2);
```

- The table created by `COMPUTE_ROC` has the columns shown in [Table 48-59](#).

**Table 48-59** `COMPUTE_ROC` Output

| Column                  | Datatype      |
|-------------------------|---------------|
| probability             | BINARY_DOUBLE |
| true_positives          | NUMBER        |
| false_negatives         | NUMBER        |
| false_positives         | NUMBER        |
| true_negatives          | NUMBER        |
| true_positive_fraction  | NUMBER        |
| false_positive_fraction | NUMBER        |

#### See Also:

*Oracle Data Mining Concepts* for details about the output of `COMPUTE_ROC`

- ROC is typically used to determine the most desirable probability threshold. This can be done by examining the true positive fraction and the false positive fraction. The true positive fraction is the percentage of all positive cases in the test data that were correctly predicted as positive. The false positive fraction is the percentage of all negative cases in the test data that were incorrectly predicted as positive.

Given a probability threshold, the following statement returns the positive predictions in an apply result table ordered by probability.

```
SELECT case_id_column_name
       FROM apply_result_table_name
       WHERE probability > probability_threshold
       ORDER BY probability DESC;
```

- There are two approaches to identifying the most desirable probability threshold. Which approach you use depends on whether or not you know the relative cost of positive versus negative class prediction errors.

If the costs are known, you can apply the relative costs to the ROC table to compute the minimum cost probability threshold. Suppose the relative cost ratio is: Positive Class Error Cost / Negative Class Error Cost = 20. Then execute a query like this.

```
WITH cost AS (
    SELECT probability_threshold, 20 * false_negatives + false_positives cost
    FROM ROC_table
    GROUP BY probability_threshold),
minCost AS (
    SELECT min(cost) minCost
    FROM cost)
SELECT max(probability_threshold) probability_threshold
FROM cost, minCost
WHERE cost = minCost;
```

If relative costs are not well known, you can simply scan the values in the ROC table (in sorted order) and make a determination about which of the displayed trade-offs (misclassified positives versus misclassified negatives) is most desirable.

```
SELECT * FROM ROC_table
       ORDER BY probability_threshold;
```

### Examples

This example uses the Naive Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id, t.prediction, t.probability
  FROM mining_data_test_v, TABLE(PREDICTION_SET(nb_sh_clas_sample USING *)) t;
```

Using the predictions and the target values from the test data, you can compute ROC as follows.

```
DECLARE
  v_area_under_curve NUMBER;
BEGIN
  DBMS_DATA_MINING.COMPUTE_ROC (
    roc_area_under_curve      => v_area_under_curve,
    apply_result_table_name   => 'nb_apply_results',
    target_table_name         => 'mining_data_test_v',
    case_id_column_name       => 'cust_id',
    target_column_name        => 'mining_data_test_v',
    roc_table_name            => 'nb_roc',
    positive_target_value     => '1',
    score_column_name         => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY');
  DBMS_OUTPUT.PUT_LINE('**** AREA UNDER ROC CURVE ****: ' ||
    ROUND(v_area_under_curve,4));
END;
/
```

The resulting AUC and a selection of columns from the ROC table are shown as follows.

```
**** AREA UNDER ROC CURVE ****: .8212
```

```
SELECT PROBABILITY, TRUE_POSITIVE_FRACTION, FALSE_POSITIVE_FRACTION
       FROM NB_ROC;
```

## 48.7.10 COMPUTE\_ROC\_PART Procedure

The `COMPUTE_ROC_PART` procedure computes Receiver Operating Characteristic (ROC), stores the results in a table in the user's schema, and returns a measure of the model accuracy. This procedure provides support to computation of evaluation metrics per-partition for partitioned models.

ROC is a test metric for binary classification models. To compute ROC, one of the target values must be designated as the positive class. `COMPUTE_ROC_PART` compares the predictions generated by the model with the actual target values in a set of test data.

ROC measures the impact of changes in the probability threshold. The probability threshold is the decision point used by the model for predictions. In binary classification, the default probability threshold is 0.5. The value predicted for each case is the one with a probability greater than 50%.

ROC can be plotted as a curve on an x-y axis. The false positive rate is placed on the x-axis. The true positive rate is placed on the y-axis. A false positive is a positive prediction for a case that is negative in the test data. A true positive is a positive prediction for a case that is positive in the test data.

`COMPUTE_ROC_PART` accepts two input streams:

- The predictions generated on the test data. The information is passed in three columns:
  - Case ID column
  - Prediction column
  - Scoring criterion column containing probabilities
- The known target values in the test data. The information is passed in two columns:
  - Case ID column
  - Target column containing the known target values

### Syntax

```
DBMS_DATA_MINING.compute_roc_part(
    roc_area_under_curve      OUT DM_NESTED_NUMERICALS,
    apply_result_table_name   IN  VARCHAR2,
    target_table_name         IN  VARCHAR2,
```

```

case_id_column_name      IN  VARCHAR2,
target_column_name       IN  VARCHAR2,
roc_table_name           IN  VARCHAR2,
positive_target_value    IN  VARCHAR2,
score_column_name        IN  VARCHAR2 DEFAULT 'PREDICTION',
score_criterion_column_name IN VARCHAR2 DEFAULT 'PROBABILITY',
score_partition_column_name IN VARCHAR2 DEFAULT 'PARTITION_NAME',
apply_result_schema_name IN  VARCHAR2 DEFAULT NULL,
target_schema_name       IN  VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 48-60 COMPUTE\_ROC\_PART Procedure Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| roc_area_under_the_curve    | <p>Output parameter containing the area under the ROC curve (AUC). The AUC measures the likelihood that an actual positive will be predicted as positive.</p> <p>The greater the AUC, the greater the flexibility of the model in accommodating trade-offs between positive and negative class predictions. AUC can be especially important when one target class is rarer or more important to identify than another.</p> <p>The output argument is changed from NUMBER to DM_NESTED_NUMERICALS.</p> |
| apply_result_table_name     | Table containing the predictions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| target_table_name           | Table containing the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| case_id_column_name         | Case ID column in the apply results table. Must match the case identifier in the targets table.                                                                                                                                                                                                                                                                                                                                                                                                       |
| target_column_name          | Target column in the targets table. Contains the known target values from the test data.                                                                                                                                                                                                                                                                                                                                                                                                              |
| roc_table_name              | <p>Table containing the ROC output. The table will be created by the procedure in the user's schema.</p> <p>The columns in the ROC table are described in the Usage Notes.</p>                                                                                                                                                                                                                                                                                                                        |
| positive_target_value       | <p>The positive class. This should be the class of interest, for which you want to calculate ROC.</p> <p>If the target column is a NUMBER, then you can use the TO_CHAR() operator to provide the value as a string.</p>                                                                                                                                                                                                                                                                              |
| score_column_name           | <p>Column containing the predictions in the apply results table.</p> <p>The default column name is PREDICTION, which is the default name created by the APPLY procedure (See "<a href="#">APPLY Procedure</a>").</p>                                                                                                                                                                                                                                                                                  |
| score_criterion_column_name | <p>Column containing the scoring criterion in the apply results table. Contains the probabilities that determine the predictions.</p> <p>The default column name is PROBABILITY, which is the default name created by the APPLY procedure (See "<a href="#">APPLY Procedure</a>").</p>                                                                                                                                                                                                                |
| score_partition_column_name | Optional parameter indicating the column which contains the name of the partition. This column slices the input test results such that each partition has independent evaluation matrices computed.                                                                                                                                                                                                                                                                                                   |

**Table 48-60 (Cont.) COMPUTE\_ROC\_PART Procedure Parameters**

| Parameter                | Description                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------|
| apply_result_schema_name | Schema of the apply results table.<br>If null, then the user's schema is assumed.                |
| target_schema_name       | Schema of the table containing the known targets.<br>If null, then the user's schema is assumed. |

**Usage Notes**

- The predictive information you pass to `COMPUTE_ROC_PART` may be generated using SQL `PREDICTION` functions, the `DBMS_DATA_MINING.APPLY` procedure, or some other mechanism. As long as you pass the appropriate data, the procedure can compute the receiver operating characteristic.
- The predictions that you pass to `COMPUTE_ROC_PART` are in a table or view specified in `apply_results_table_name`.

```
CREATE TABLE apply_result_table_name AS (  
    case_id_column_name          VARCHAR2,  
    score_column_name            VARCHAR2,  
    score_criterion_column_name  VARCHAR2);
```

- The `COMPUTE_ROC_PART` table has the following columns:

**Table 48-61 COMPUTE\_ROC\_PART Output**

| Column                  | Datatype      |
|-------------------------|---------------|
| probability             | BINARY_DOUBLE |
| true_positives          | NUMBER        |
| false_negatives         | NUMBER        |
| false_positives         | NUMBER        |
| true_negatives          | NUMBER        |
| true_positive_fraction  | NUMBER        |
| false_positive_fraction | NUMBER        |

 **See Also:**

*Oracle Data Mining Concepts* for details about the output of `COMPUTE_ROC_PART`

- ROC is typically used to determine the most desirable probability threshold. This can be done by examining the true positive fraction and the false positive fraction. The true positive fraction is the percentage of all positive cases in the test data that were correctly predicted as positive. The false positive fraction is the percentage of all negative cases in the test data that were incorrectly predicted as positive.

Given a probability threshold, the following statement returns the positive predictions in an apply result table ordered by probability.

```
SELECT case_id_column_name
       FROM apply_result_table_name
       WHERE probability > probability_threshold
       ORDER BY probability DESC;
```

- There are two approaches to identify the most desirable probability threshold. The approach you use depends on whether you know the relative cost of positive versus negative class prediction errors.

If the costs are known, then you can apply the relative costs to the ROC table to compute the minimum cost probability threshold. Suppose the relative cost ratio is: Positive Class Error Cost / Negative Class Error Cost = 20. Then execute a query as follows:

```
WITH cost AS (
  SELECT probability_threshold, 20 * false_negatives + false_positives cost
  FROM ROC_table
  GROUP BY probability_threshold),
  minCost AS (
    SELECT min(cost) minCost
    FROM cost)
  SELECT max(probability_threshold)probability_threshold
  FROM cost, minCost
  WHERE cost = minCost;
```

If relative costs are not well known, then you can simply scan the values in the ROC table (in sorted order) and make a determination about which of the displayed trade-offs (misclassified positives versus misclassified negatives) is most desirable.

```
SELECT * FROM ROC_table
       ORDER BY probability_threshold;
```

## Examples

This example uses the Naive Bayes model `nb_sh_clas_sample`, which is created by one of the Oracle Data Mining sample programs.

The following statement applies the model to the test data and stores the predictions and probabilities in a table.

```
CREATE TABLE nb_apply_results AS
  SELECT cust_id, t.prediction, t.probability
  FROM mining_data_test_v, TABLE(PREDICTION_SET(nb_sh_clas_sample USING *)) t;
```

Using the predictions and the target values from the test data, you can compute ROC as follows.

```
DECLARE
  v_area_under_curve NUMBER;
BEGIN
  DBMS_DATA_MINING.COMPUTE_ROC_PART (
    roc_area_under_curve      => v_area_under_curve,
    apply_result_table_name   => 'nb_apply_results',
    target_table_name         => 'mining_data_test_v',
    case_id_column_name       => 'cust_id',
    target_column_name        => 'affinity_card',
    roc_table_name            => 'nb_roc',
    positive_target_value     => '1',
    score_column_name         => 'PREDICTION',
    score_criterion_column_name => 'PROBABILITY');
    score_partition_column_name => 'PARTITION_NAME'
```

```

        DBMS_OUTPUT.PUT_LINE('**** AREA UNDER ROC CURVE ****: ' ||
        ROUND(v_area_under_curve,4));
END;
/

```

The resulting AUC and a selection of columns from the ROC table are shown as follows.

```

**** AREA UNDER ROC CURVE ****: .8212

SELECT PROBABILITY, TRUE_POSITIVE_FRACTION, FALSE_POSITIVE_FRACTION
       FROM NB_ROC;

```

| PROBABILITY | TRUE_POSITIVE_FRACTION | FALSE_POSITIVE_FRACTION |
|-------------|------------------------|-------------------------|
| .00000      | 1                      | 1                       |

## 48.7.11 CREATE\_MODEL Procedure

This procedure creates a mining model with a given mining function.

### Syntax

```

DBMS_DATA_MINING.CREATE_MODEL (
    model_name          IN VARCHAR2,
    mining_function      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    case_id_column_name IN VARCHAR2,
    target_column_name  IN VARCHAR2 DEFAULT NULL,
    settings_table_name IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL,
    settings_schema_name IN VARCHAR2 DEFAULT NULL,
    xform_list          IN TRANSFORM_LIST DEFAULT NULL);

```

### Parameters

**Table 48-62 CREATE\_MODEL Procedure Parameters**

| Parameter           | Description                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model_name          | Name of the model in the form <i>[schema_name.]model_name</i> . If you do not specify a schema, then your own schema is used.<br>See the Usage Notes for model naming restrictions. |
| mining_function     | The mining function. Values are listed in <a href="#">Table 48-3</a> .                                                                                                              |
| data_table_name     | Table or view containing the build data                                                                                                                                             |
| case_id_column_name | Case identifier column in the build data.                                                                                                                                           |

**Table 48-62 (Cont.) CREATE\_MODEL Procedure Parameters**

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| target_column_name   | For supervised models, the target column in the build data. NULL for unsupervised models.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| settings_table_name  | Table containing build settings for the model. NULL if there is no settings table (only default settings are used).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| data_schema_name     | Schema hosting the build data. If NULL, then the user's schema is assumed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| settings_schema_name | Schema hosting the settings table. | xform_list           | <p>A list of transformations to be used in addition to or instead of automatic transformations, depending on the value of the PREP_AUTO setting. (See <a href="#">"Automatic Data Preparation"</a>.)</p> <p>The datatype of xform_list is TRANSFORM_LIST, which consists of records of type TRANSFORM_REC. Each TRANSFORM_REC specifies the transformation information for a single attribute.</p> <pre> TYPE   TRANSFORM_REC      IS RECORD (     attribute_name     VARCHAR2(4000),     attribute_subname  VARCHAR2(4000),     expression         EXPRESSION_REC,     reverse_expression EXPRESSION_REC,     attribute_spec     VARCHAR2(4000)); </pre> <p>The expression field stores a SQL expression for transforming the attribute. The reverse_expression field stores a SQL expression for reversing the transformation in model details and, if the attribute is a target, in the results of scoring. The SQL expressions are manipulated by routines in the DBMS_DATA_MINING_TRANSFORM package:</p> <ul style="list-style-type: none"> <li>• <a href="#">SET_EXPRESSION Procedure</a></li> <li>• <a href="#">GET_EXPRESSION Function</a></li> <li>• <a href="#">SET_TRANSFORM Procedure</a></li> </ul> <p>The attribute_spec field identifies individualized treatment for the attribute. See the Usage Notes for details.</p> <p>See <a href="#">Table 49-1</a> for details about the TRANSFORM_REC type.</p> |

### Usage Notes

- You can use the attribute\_spec field of the xform\_list argument to identify an attribute as unstructured text or to disable Automatic Data Preparation for the attribute. The attribute\_spec can have the following values:
  - TEXT: Indicates that the attribute contains unstructured text. The TEXT value may optionally be followed by POLICY\_NAME, TOKEN\_TYPE, MAX\_FEATURES, and MIN\_DOCUMENTS parameters.
 

TOKEN\_TYPE has the following possible values: NORMAL, STEM, THEME, SYNONYM, BIGRAM, STEM\_BIGRAM. SYNONYM may be optionally followed by a thesaurus name in square brackets.

MAX\_FEATURES specifies the maximum number of tokens extracted from the text.

`MIN_DOCUMENTS` specifies the minimal number of documents in which every selected token shall occur. (For information about creating a text policy, see `CTX_DDL.CREATE_POLICY` in *Oracle Text Reference*).

Oracle Data Mining can process columns of `VARCHAR2/CHAR`, `CLOB`, `BLOB`, and `BFILE` as text. If the column is `VARCHAR2` or `CHAR` and you do not specify `TEXT`, Oracle Data Mining will process the column as categorical data. If the column is `CLOB`, then Oracle Data Mining will process it as text by default (You do not need to specify it as `TEXT`. However, you do need to provide an Oracle Text Policy in the settings). If the column is `BLOB` or `BFILE`, you must specify it as `TEXT`, otherwise `CREATE_MODEL` will return an error.

If you specify `TEXT` for a nested column or for an attribute in a nested column, `CREATE_MODEL` will return an error.

- `NOPREP`: Disables ADP for the attribute. When ADP is `OFF`, the `NOPREP` value is ignored.

You can specify `NOPREP` for a nested column, but not for an attribute in a nested column. If you specify `NOPREP` for an attribute in a nested column when ADP is on, `CREATE_MODEL` will return an error.

2. You can obtain information about a model by querying the Data Dictionary views.

```
ALL/USER/DBA_MINING_MODELS
ALL/USER/DBA_MINING_MODEL_ATTRIBUTES
ALL/USER/DBA_MINING_MODEL_SETTINGS
ALL/USER/DBA_MINING_MODEL_VIEWS
ALL/USER/DBA_MINING_MODEL_PARTITIONS
ALL/USER/DBA_MINING_MODEL_XFORMS
```

You can obtain information about model attributes by querying the model details through model views. Refer to *Oracle Data Mining User's Guide*.

3. The naming rules for models are more restrictive than the naming rules for most database schema objects. A model name must satisfy the following additional requirements:

- It must be 123 or fewer characters long.
- It must be a nonquoted identifier. Oracle requires that nonquoted identifiers contain only alphanumeric characters, the underscore (`_`), dollar sign (`$`), and pound sign (`#`); the initial character must be alphabetic. Oracle strongly discourages the use of the dollar sign and pound sign in nonquoted literals.

Naming requirements for schema objects are fully documented in *Oracle Database SQL Language Reference*.

4. To build a partitioned model, you must provide additional settings.

The setting for partitioning columns are as follows:

```
INSERT INTO settings_table VALUES ('ODMS_PARTITION_COLUMNS', 'GENDER,
AGE');
```

To set user-defined partition number for a model, the setting is as follows:

```
INSERT INTO settings_table VALUES ('ODMS_MAX_PARTITIONS', '10');
```

The default value for maximum number of partitions is 1000.

5. By passing an `xform_list` to `CREATE_MODEL`, you can specify a list of transformations to be performed on the input data. If the `PREP_AUTO` setting is `ON`, the transformations are used in addition to the automatic transformations. If the `PREP_AUTO` setting is `OFF`, the specified

transformations are the only ones implemented by the model. In both cases, transformation definitions are embedded in the model and executed automatically whenever the model is applied. See ["Automatic Data Preparation"](#). Other transforms that can be specified with `xform_list` include `FORCE_IN`. Refer to *Oracle Data Mining User's Guide*.

## Examples

The first example builds a Classification model using the Support Vector Machine algorithm.

```
-- Create the settings table
CREATE TABLE svm_model_settings (
  setting_name  VARCHAR2(30),
  setting_value VARCHAR2(30));

-- Populate the settings table
-- Specify SVM. By default, Naive Bayes is used for classification.
-- Specify ADP. By default, ADP is not used.
BEGIN
  INSERT INTO svm_model_settings (setting_name, setting_value) VALUES
    (dbms_data_mining.algo_name, dbms_data_mining.algo_support_vector_machines);
  INSERT INTO svm_model_settings (setting_name, setting_value) VALUES
    (dbms_data_mining.prep_auto, dbms_data_mining.prep_auto_on);
  COMMIT;
END;
/

-- Create the model using the specified settings
BEGIN
  DBMS_DATA_MINING.CREATE_MODEL(
    model_name          => 'svm_model',
    mining_function      => dbms_data_mining.classification,
    data_table_name      => 'mining_data_build_v',
    case_id_column_name => 'cust_id',
    target_column_name   => 'affinity_card',
    settings_table_name => 'svm_model_settings');
END;
/
```

You can display the model settings with the following query:

```
SELECT * FROM user_mining_model_settings
       WHERE model_name IN 'SVM_MODEL';
```

| MODEL_NAME | SETTING_NAME           | SETTING_VALUE                | SETTING |
|------------|------------------------|------------------------------|---------|
| SVM_MODEL  | ALGO_NAME              | ALGO_SUPPORT_VECTOR_MACHINES | INPUT   |
| SVM_MODEL  | SVMS_STD_DEV           | 3.004524                     | DEFAULT |
| SVM_MODEL  | PREP_AUTO              | ON                           | INPUT   |
| SVM_MODEL  | SVMS_COMPLEXITY_FACTOR | 1.887389                     | DEFAULT |
| SVM_MODEL  | SVMS_KERNEL_FUNCTION   | SVMS_LINEAR                  | DEFAULT |
| SVM_MODEL  | SVMS_CONV_TOLERANCE    | .001                         | DEFAULT |

The following is an example of querying a model view instead of the older `GEL_MODEL_DETAILS_SVM` routine.

```
SELECT target_value, attribute_name, attribute_value, coefficient FROM
DM$VLSVM_MODEL;
```

The second example creates an Anomaly Detection model. Anomaly Detection uses SVM Classification without a target. This example uses the same settings table created for the SVM Classification model in the first example.

```
BEGIN
  DBMS_DATA_MINING.CREATE_MODEL(
    model_name          => 'anomaly_detect_model',
    mining_function     => dbms_data_mining.classification,
    data_table_name     => 'mining_data_build_v',
    case_id_column_name => 'cust_id',
    target_column_name  => null,
    settings_table_name => 'svm_model_settings');
END;
/
```

This query shows that the models created in these examples are the only ones in your schema.

```
SELECT model_name, mining_function, algorithm FROM user_mining_models;
```

| MODEL_NAME           | MINING_FUNCTION | ALGORITHM               |
|----------------------|-----------------|-------------------------|
| SVM_MODEL            | CLASSIFICATION  | SUPPORT_VECTOR_MACHINES |
| ANOMALY_DETECT_MODEL | CLASSIFICATION  | SUPPORT_VECTOR_MACHINES |

This query shows that only the SVM Classification model has a target.

```
SELECT model_name, attribute_name, attribute_type, target
FROM user_mining_model_attributes
WHERE target = 'YES';
```

| MODEL_NAME | ATTRIBUTE_NAME | ATTRIBUTE_TYPE | TARGET |
|------------|----------------|----------------|--------|
| SVM_MODEL  | AFFINITY_CARD  | CATEGORICAL    | YES    |

## 48.7.12 CREATE\_MODEL2 Procedure

The `CREATE_MODEL2` procedure is an alternate procedure to the `CREATE_MODEL` procedure, which enables creating a model without extra persistence stages. In the `CREATE_MODEL` procedure, the input is a table or a view and if such an object is not already present, the user must create it. By using the `CREATE_MODEL2` procedure, the user does not need to create such transient database objects.

### Syntax

```
DBMS_DATA_MINING.CREATE_MODEL2 (
  model_name          IN VARCHAR2,
  mining_function     IN VARCHAR2,
  data_query          IN CLOB,
  set_list            IN SETTING_LIST,
  case_id_column_name IN VARCHAR2 DEFAULT NULL,
  target_column_name  IN VARCHAR2 DEFAULT NULL,
  xform_list          IN TRANSFORM_LIST DEFAULT NULL);
```

## Parameters

**Table 48-63 CREATE\_MODEL2 Procedure Parameters**

| Parameter           | Description                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model_name          | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, then the current schema is used.<br>See the Usage Notes, <a href="#">CREATE_MODEL Procedure</a> for model naming restrictions. |
| mining_function     | The mining function. Values are listed in <a href="#">DBMS_DATA_MINING — Mining Function Settings</a> .                                                                                                                |
| data_query          | A query which provides training data for building the model.                                                                                                                                                           |
| set_list            | Specifies the SETTING_LIST<br>SETTING_LIST is a table of CLOB index by VARCHAR2 (30); Where the index is the setting name and the CLOB is the setting value for that name.                                             |
| case_id_column_name | Case identifier column in the build data.                                                                                                                                                                              |
| target_column_name  | For supervised models, the target column in the build data. NULL for unsupervised models.                                                                                                                              |
| xform_list          | Refer to <a href="#">CREATE_MODEL Procedure</a> .                                                                                                                                                                      |

## Usage Notes

Refer to [CREATE\\_MODEL Procedure](#) for Usage Notes.

## Examples

The following example uses the Support Vector Machine algorithm.

```

declare
  v_setlst DBMS_DATA_MINING.SETTING_LIST;

BEGIN
  v_setlst(dbms_data_mining.algo_name) :=
dbms_data_mining.algo_support_vector_machines;
  v_setlst(dbms_data_mining.prep_auto) := dbms_data_mining.prep_auto_on;

DBMS_DATA_MINING.CREATE_MODEL2 (
  model_name          => 'svm_model',
  mining_function      => dbms_data_mining.classification,
  data_query           => 'select * from mining_data_build_v',
  data_table_name      => 'mining_data_build_v',
  case_id_column_name => 'cust_id',
  target_column_name  => 'affinity_card',
  set_list             => v_setlst,
  case_id_column_name => 'cust_id',
  target_column_name  => 'affinity_card');
END;
/

```

## 48.7.13 Create Model Using Registration Information

Create model function fetches the setting information from JSON object.

### Usage Notes

If an algorithm is registered, user can create model using the registered algorithm name. Since all R scripts and default setting values are already registered, providing the value through the setting table is not necessary. This makes the use of this algorithm easier.

### Examples

The first example builds a Classification model using the GLM algorithm.

```
CREATE TABLE GLM_RDEMO_SETTINGS_CL (

    setting_name VARCHAR2(30),
    setting_value VARCHAR2(4000));
BEGIN
    INSERT INTO GLM_RDEMO_SETTINGS_CL VALUES
        ('ALGO_EXTENSIBLE_LANG', 'R');
    INSERT INTO GLM_RDEMO_SETTINGS_CL VALUES
        (dbms_data_mining.ralg_registration_algo_name, 't1');
    INSERT INTO GLM_RDEMO_SETTINGS_CL VALUES
        (dbms_data_mining.odms_formula,
        'AGE + EDUCATION + HOUSEHOLD_SIZE + OCCUPATION');
    INSERT INTO GLM_RDEMO_SETTINGS_CL VALUES
        ('RALG_PARAMETER_FAMILY', 'binomial(logit)');
END;
/
BEGIN
    DBMS_DATA_MINING.CREATE_MODEL(
        model_name          => 'GLM_RDEMO_CLASSIFICATION',
        mining_function      => dbms_data_mining.classification,
        data_table_name      => 'mining_data_build_v',
        case_id_column_name  => 'CUST_ID',
        target_column_name   => 'AFFINITY_CARD',
        settings_table_name  => 'GLM_RDEMO_SETTINGS_CL');
END;
/
```

## 48.7.14 DROP\_ALGORITHM Procedure

This function is used to drop the registered algorithm information.

### Syntax

```
DBMS_DATA_MINING.DROP_ALGORITHM (algorithm_name IN VARCHAR2(30),
                                cascade          IN BOOLEAN default FALSE)
```

### Parameters

**Table 48-64 DROP\_ALGORITHM Procedure Parameters**

| Parameter      | Description            |
|----------------|------------------------|
| algorithm_name | Name of the algorithm. |
| cascade        |                        |

**Table 48-64 (Cont.) DROP\_ALGORITHM Procedure Parameters**

| Parameter            | Description                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cascade</code> | If the cascade option is <code>TRUE</code> , all the models with this algorithms are forced to drop. There after, the algorithm is dropped. The default value is <code>FALSE</code> . |

#### Usage Note

- To drop a mining model, you must be the owner or you must have the `RQADMIN` privilege. See *Oracle Data Mining User's Guide* for information about privileges for data mining.
- Make sure a model is not built on the algorithm, then drop the algorithm from the system table.
- If you try to drop an algorithm with a model built on it, then an error is displayed.

## 48.7.15 DROP\_PARTITION Procedure

The `DROP_PARTITION` procedure drops a single partition that is specified in the parameter `partition_name`.

#### Syntax

```
DBMS_DATA_MINING.DROP_PARTITION (
    model_name          IN VARCHAR2,
    partition_name      IN VARCHAR2);
```

#### Parameters

**Table 48-65 DROP\_PARTITION Procedure Parameters**

| Parameters                  | Description                                                                                                                                |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the mining model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>partition_name</code> | Name of the partition that must be dropped.                                                                                                |

## 48.7.16 DROP\_MODEL Procedure

This procedure deletes the specified mining model.

#### Syntax

```
DBMS_DATA_MINING.DROP_MODEL (model_name IN VARCHAR2,
                             force       IN BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 48-66 DROP\_MODEL Procedure Parameters**

| Parameter  | Description                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| model_name | Name of the mining model in the form [schema_name.]model_name. If you do not specify a schema, your own schema is used.                                   |
| force      | Forces the mining model to be dropped even if it is invalid. A mining model may be invalid if a serious system error interrupted the model build process. |

## Usage Note

To drop a mining model, you must be the owner or you must have the `DROP ANY MINING MODEL` privilege. See *Oracle Data Mining User's Guide* for information about privileges for data mining.

## Example

You can use the following command to delete a valid mining model named `nb_sh_clas_sample` that exists in your schema.

```
BEGIN
  DBMS_DATA_MINING.DROP_MODEL(model_name => 'nb_sh_clas_sample');
END;
/
```

## 48.7.17 EXPORT\_MODEL Procedure

This procedure exports the specified data mining models to a dump file set.

To import the models from the dump file set, use the [IMPORT\\_MODEL Procedure](#). `EXPORT_MODEL` and `IMPORT_MODEL` use Oracle Data Pump technology.

When Oracle Data Pump is used to export/import an entire schema or database, the mining models in the schema or database are included. However, `EXPORT_MODEL` and `IMPORT_MODEL` are the only utilities that support the export/import of individual models.

### See Also:

*Oracle Database Utilities* for information about Oracle Data Pump

*Oracle Data Mining User's Guide* for more information about exporting and importing mining models

## Syntax

```
DBMS_DATA_MINING.EXPORT_MODEL (
  filename          IN VARCHAR2,
  directory         IN VARCHAR2,
  model_filter      IN VARCHAR2 DEFAULT NULL,
  filesize          IN VARCHAR2 DEFAULT NULL,
  operation         IN VARCHAR2 DEFAULT NULL,
  remote_link       IN VARCHAR2 DEFAULT NULL,
  jobname           IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 48-67 EXPORT\_MODEL Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename     | <p>Name of the dump file set to which the models should be exported. The name must be unique within the schema.</p> <p>The dump file set can contain one or more files. The number of files in a dump file set is determined by the size of the models being exported (both metadata and data) and a specified or estimated maximum file size. You can specify the file size in the <code>filesize</code> parameter, or you can use the <code>operation</code> parameter to cause Oracle Data Pump to estimate the file size. If the size of the models to export is greater than the maximum file size, one or more additional files are created.</p> <p>When the export operation completes successfully, the name of the dump file set is automatically expanded to <code>filename01.dmp</code>, even if there is only one file in the dump set. If there are additional files, they are named sequentially as <code>filename02.dmp</code>, <code>filename03.dmp</code>, and so forth.</p> |
| directory    | <p>Name of a pre-defined directory object that specifies where the dump file set should be created.</p> <p>The exporting user must have read/write privileges on the directory object and on the file system directory that it identifies.</p> <p>See <i>Oracle Database SQL Language Reference</i> for information about directory objects.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| model_filter | <p>Optional parameter that specifies which model or models to export. If you do not specify a value for <code>model_filter</code>, all models in the schema are exported. You can also specify <code>NULL</code> (the default) or <code>'ALL'</code> to export all models.</p> <p>You can export individual models by name and groups of models based on mining function or algorithm. For instance, you could export all regression models or all Naive Bayes models. Examples are provided in <a href="#">Table 48-68</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| filesize     | <p>Optional parameter that specifies the maximum size of a file in the dump file set. The size may be specified in bytes, kilobytes (K), megabytes (M), or gigabytes (G). The default size is 50 MB.</p> <p>If the size of the models to export is larger than <code>filesize</code>, one or more additional files are created within the dump set. See the description of the <code>filename</code> parameter for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| operation    | <p>Optional parameter that specifies whether or not to estimate the size of the files in the dump set. By default the size is not estimated and the value of the <code>filesize</code> parameter determines the size of the files.</p> <p>You can specify either of the following values for <code>operation</code>:</p> <ul style="list-style-type: none"> <li><code>'EXPORT'</code> — Export all or the specified models. (Default)</li> <li><code>'ESTIMATE'</code> — Estimate the size of the exporting models.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| remote_link  | <p>Optional parameter that specifies the name of a database link to a remote system. The default value is <code>NULL</code>. A database link is a schema object in a local database that enables access to objects in a remote database. When you specify a value for <code>remote_link</code>, you can export the models in the remote database. The <code>EXP_FULL_DATABASE</code> role is required for exporting the remote models. The <code>EXP_FULL_DATABASE</code> privilege, the <code>CREATE DATABASE LINK</code> privilege, and other privileges may also be required.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 48-67 (Cont.) EXPORT\_MODEL Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jobname   | <p>Optional parameter that specifies the name of the export job. By default, the name has the form <i>username_exp_nnnn</i>, where <i>nnnn</i> is a number. For example, a job name in the SCOTT schema might be SCOTT_exp_134.</p> <p>If you specify a job name, it must be unique within the schema. The maximum length of the job name is 30 characters.</p> <p>A log file for the export job, named <i>jobname.log</i>, is created in the same directory as the dump file set.</p> |

### Usage Notes

The `model_filter` parameter specifies which models to export. You can list the models by name, or you can specify all models that have the same mining function or algorithm. You can query the `USER_MINING_MODELS` view to list the models in your schema.

```
SQL> describe user_mining_models
Name                               Null?    Type
-----
MODEL_NAME                         NOT NULL VARCHAR2(30)
MINING_FUNCTION                    VARCHAR2(30)
ALGORITHM                          VARCHAR2(30)
CREATION_DATE                      NOT NULL DATE
BUILD_DURATION                     NUMBER
MODEL_SIZE                         NUMBER
COMMENTS                           VARCHAR2(4000)
```

Examples of model filters are provided in [Table 48-68](#).

**Table 48-68 Sample Values for the Model Filter Parameter**

| Sample Value                       | Meaning                                                                                          |
|------------------------------------|--------------------------------------------------------------------------------------------------|
| 'mymodel'                          | Export the model named mymodel                                                                   |
| 'name= 'mymodel''                  | Export the model named mymodel                                                                   |
| 'name IN ('mymodel2','mymodel3')'  | Export the models named mymodel2 and mymodel3                                                    |
| 'ALGORITHM_NAME = 'NAIVE_BAYES''   | Export all Naive Bayes models. See <a href="#">Table 48-5</a> for a list of algorithm names.     |
| 'FUNCTION_NAME = 'CLASSIFICATION'' | Export all classification models. See <a href="#">Table 48-3</a> for a list of mining functions. |

### Examples

- The following statement exports all the models in the `DMUSER3` schema to a dump file set called `models_out` in the directory `$ORACLE_HOME/rdbms/log`. This directory is mapped to a directory object called `DATA_PUMP_DIR`. The `DMUSER3` user has read/write access to the directory and to the directory object.

```
SQL>execute dbms_data_mining.export_model ('models_out', 'DATA_PUMP_DIR');
```

You can exit SQL\*Plus and list the resulting dump file and log file.

```
SQL>EXIT
>cd $ORACLE_HOME/rdbms/log
>ls
>DMUSER3_exp_1027.log  models_out01.dmp
```

2. The following example uses the same directory object and is executed by the same user. This example exports the models called NMF\_SH\_SAMPLE and SVMR\_SH\_REGR\_SAMPLE to a different dump file set in the same directory.

```
SQL>EXECUTE DBMS_DATA_MINING.EXPORT_MODEL ( 'models2_out', 'DATA_PUMP_DIR',
      'name in (''NMF_SH_SAMPLE'', ''SVMR_SH_REGR_SAMPLE'')');
SQL>EXIT
>cd $ORACLE_HOME/rdbms/log
>ls
>DMUSER3_exp_1027.log  models_out01.dmp
  DMUSER3_exp_924.log  models2_out01.dmp
```

3. The following examples show how to export models with specific algorithm and mining function names.

```
SQL>EXECUTE DBMS_DATA_MINING.EXPORT_MODEL('algo.dmp', 'DM_DUMP',
      'ALGORITHM_NAME IN (''O_CLUSTER'', ''GENERALIZED_LINEAR_MODEL'',
      ''SUPPORT_VECTOR_MACHINES'', ''NAIVE_BAYES'')');

SQL>EXECUTE DBMS_DATA_MINING.EXPORT_MODEL('func.dmp', 'DM_DUMP',
      'FUNCTION_NAME IN (CLASSIFICATION, CLUSTERING, FEATURE_EXTRACTION)');
```

## 48.7.18 EXPORT\_SERMODEL Procedure

This procedure exports the model in a serialized format so that they can be moved to another platform for scoring.

When exporting a model in serialized format, the user must pass in an empty BLOB locator and specify the model name to be exported. If the model is partitioned, the user can optionally select an individual partition to export, otherwise all partitions are exported. The returned BLOB contains the content that can be deployed.

### Syntax

```
DBMS_DATA_MINING.EXPORT_SERMODEL (
  model_data      IN OUT NOCOPY BLOB,
  model_name      IN VARCHAR2,
  partition_name  IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 48-69 EXPORT\_SERMODEL Procedure Parameters**

| Parameter      | Description                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| model_data     | Provides serialized model data.                                                                                              |
| model_name     | Name of the mining model in the form [schema_name.]model_name. If you do not specify a schema, then your own schema is used. |
| partition_name | Name of the partition that must be exported.                                                                                 |

## Examples

The following statement exports all the models in a serialized format.

```
DECLARE
  v_blob blob;
BEGIN
  dbms_lob.createtemporary(v_blob, FALSE);
  dbms_data_mining.export_sermodel(v_blob, 'MY_MODEL');
  -- save v_blob somewhere (e.g., bfile, etc.)
  dbms_lob.freetemporary(v_blob);
END;
/
```

### See Also:

*Oracle Data Mining User's Guide* for more information about exporting and importing mining models

## 48.7.19 FETCH\_JSON\_SCHEMA Procedure

User can fetch and read JSON schema from the `ALL_MINING_ALGORITHMS` view. This function returns the pre-registered JSON schema for R extensible algorithms.

### Syntax

```
DBMS_DATA_MINING.FETCH_JSON_SCHEMA RETURN CLOB;
```

### Parameters

**Table 48-70** FETCH\_JSON\_SCHEMA Procedure Parameters

| Parameter | Description                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------|
| RETURN    | This function returns the pre-registered JSON schema for R extensibility.<br>The default value is CLOB. |

### Usage Note

If a user wants to register a new algorithm using the algorithm registration function, they must fetch and follow the pre-registered JSON schema using this function, when they create the required JSON object metadata, and then pass it to the registration function.

## 48.7.20 GET\_ASSOCIATION\_RULES Function

The `GET_ASSOCIATION_RULES` function returns the rules produced by an Association model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*

You can specify filtering criteria to `GET_ASSOCIATION_RULES` to return a subset of the rules. Filtering criteria can improve the performance of the table function. If the number of rules is

large, then the greatest performance improvement will result from specifying the `topn` parameter.

### Syntax

```
DBMS_DATA_MINING.get_association_rules(
    model_name      IN VARCHAR2,
    topn            IN NUMBER DEFAULT NULL,
    rule_id         IN INTEGER DEFAULT NULL,
    min_confidence  IN NUMBER DEFAULT NULL,
    min_support     IN NUMBER DEFAULT NULL,
    max_rule_length IN INTEGER DEFAULT NULL,
    min_rule_length IN INTEGER DEFAULT NULL,
    sort_order      IN ORA_MINING_VARCHAR2_NT DEFAULT NULL,
    antecedent_items IN DM_ITEMS DEFAULT NULL,
    consequent_items IN DM_ITEMS DEFAULT NULL,
    min_lift        IN NUMBER DEFAULT NULL,
    partition_name  IN VARCHAR2 DEFAULT NULL)
RETURN DM_Rules PIPELINED;
```

### Parameters

**Table 48-71 GET\_ASSOCIATION\_RULES Function Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>      | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.<br><br>This is the only required parameter of <code>GET_ASSOCIATION_RULES</code> . All other parameters specify optional filters on the rules to return.                                                                                                                                                                                                                                                                                                                                 |
| <code>topn</code>            | Returns the <i>n</i> top rules ordered by confidence and then support, both descending. If you specify a sort order, then the top <i>n</i> rules are derived after the sort is performed.<br><br>If <code>topn</code> is specified and no maximum or minimum rule length is specified, then the only columns allowed in the sort order are <code>RULE_CONFIDENCE</code> and <code>RULE_SUPPORT</code> . If <code>topn</code> is specified and a maximum or minimum rule length is specified, then <code>RULE_CONFIDENCE</code> , <code>RULE_SUPPORT</code> , and <code>NUMBER_OF_ITEMS</code> are allowed in the sort order. |
| <code>rule_id</code>         | Identifier of the rule to return. If you specify a value for <code>rule_id</code> , do not specify values for the other filtering parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>min_confidence</code>  | Returns the rules with confidence greater than or equal to this number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>min_support</code>     | Returns the rules with support greater than or equal to this number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>max_rule_length</code> | Returns the rules with a length less than or equal to this number.<br><br>Rule length refers to the number of items in the rule (See <code>NUMBER_OF_ITEMS</code> in <a href="#">Table 48-72</a> ). For example, in the rule <code>A=&gt;B</code> (if A, then B), the number of items is 2.<br><br>If <code>max_rule_length</code> is specified, then the <code>NUMBER_OF_ITEMS</code> column is permitted in the sort order.                                                                                                                                                                                                |
| <code>min_rule_length</code> | Returns the rules with a length greater than or equal to this number. See <code>max_rule_length</code> for a description of rule length.<br><br>If <code>min_rule_length</code> is specified, then the <code>NUMBER_OF_ITEMS</code> column is permitted in the sort order.                                                                                                                                                                                                                                                                                                                                                   |

**Table 48-71 (Cont.) GET\_ASSOCIATION\_RULES Function Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sort_order       | <p>Sorts the rules by the values in one or more of the returned columns. Specify one or more column names, each followed by ASC for ascending order or DESC for descending order. (See <a href="#">Table 48-72</a> for the column names.)</p> <p>For example, to sort the result set in descending order first by the NUMBER_OF_ITEMS column, then by the RULE_CONFIDENCE column, you must specify:</p> <pre>ORA_MINING_VARCHAR2_NT('NUMBER_OF_ITEMS DESC', 'RULE_CONFIDENCE DESC')</pre> <p>If you specify topn, the results will vary depending on the sort order.</p> <p>By default, the results are sorted by Confidence in descending order, then by Support in descending order.</p> |
| antecedent_items | Returns the rules with these items in the antecedent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| consequent_items | Returns the rules with this item in the consequent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| min_lift         | Returns the rules with lift greater than or equal to this number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| partition_name   | Specifies a partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Return Values

The object type returned by GET\_ASSOCIATION\_RULES is described in [Table 48-72](#). For descriptions of each field, see the Usage Notes.

**Table 48-72 GET\_ASSOCIATION\_RULES Function Return Values**

| Return Value         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |                 |                   |                 |                      |                            |                     |         |                     |                 |                   |         |                      |         |                    |         |                 |           |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-----------------|-------------------|-----------------|----------------------|----------------------------|---------------------|---------|---------------------|-----------------|-------------------|---------|----------------------|---------|--------------------|---------|-----------------|-----------|
| DM_RULES             | <p>A set of rows of type DM_RULE. The rows have the following columns:</p> <table> <tr> <td>(rule_id</td><td>INTEGER,</td></tr> <tr> <td>antecedent</td><td>DM_PREDICATES,</td></tr> <tr> <td>consequent</td><td>DM_PREDICATES,</td></tr> <tr> <td>rule_support</td><td>NUMBER,</td></tr> <tr> <td>rule_confidence</td><td>NUMBER,</td></tr> <tr> <td>rule_lift</td><td>NUMBER,</td></tr> <tr> <td>antecedent_support</td><td>NUMBER,</td></tr> <tr> <td>consequent_support</td><td>NUMBER,</td></tr> <tr> <td>number_of_items</td><td>INTEGER )</td></tr> </table>                                                                | (rule_id        | INTEGER,        | antecedent        | DM_PREDICATES,  | consequent           | DM_PREDICATES,             | rule_support        | NUMBER, | rule_confidence     | NUMBER,         | rule_lift         | NUMBER, | antecedent_support   | NUMBER, | consequent_support | NUMBER, | number_of_items | INTEGER ) |

## Usage Notes

1. This table function pipes out rows of type `DM_RULES`. For information on Data Mining data types and piped output from table functions, see "[Datatypes](#)".
2. The columns returned by `GET_ASSOCIATION_RULES` are described as follows:

| Column in <code>DM_RULES</code> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <code>rule_id</code>            | Unique identifier of the rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>antecedent</code>         | <p>The independent condition in the rule. When this condition exists, the dependent condition in the consequent also exists.</p> <p>The condition is a combination of attribute values called a predicate (<code>DM_PREDICATE</code>). The predicate specifies a condition for each attribute. The condition may specify equality (=), inequality (&lt;&gt;), greater than (&gt;), less than (&lt;), greater than or equal to (&gt;=), or less than or equal to (&lt;=) a given value.</p> <p>Support and Confidence for each attribute condition in the antecedent is returned in the predicate. Support is the number of transactions that satisfy the antecedent. Confidence is the likelihood that a transaction will satisfy the antecedent.</p> <p><b>Note:</b> The occurrence of the attribute as a <code>DM_PREDICATE</code> indicates the presence of the item in the transaction. The actual value for <code>attribute_num_value</code> or <code>attribute_str_value</code> is meaningless. For example, the following predicate indicates that 'Mouse Pad' is present in the transaction <i>even though</i> the attribute value is NULL.</p> <pre>DM_PREDICATE('PROD_NAME',               'Mouse Pad', '= ', NULL, NULL, NULL, NULL))</pre> |
| <code>consequent</code>         | <p>The dependent condition in the rule. This condition exists when the antecedent exists.</p> <p>The consequent, like the antecedent, is a predicate (<code>DM_PREDICATE</code>).</p> <p>Support and confidence for each attribute condition in the consequent is returned in the predicate. Support is the number of transactions that satisfy the consequent. Confidence is the likelihood that a transaction will satisfy the consequent.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>rule_support</code>       | The number of transactions that satisfy the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>rule_confidence</code>    | The likelihood of a transaction satisfying the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>rule_lift</code>          | The degree of improvement in the prediction over random chance when the rule is satisfied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>antecedent_support</code> | The ratio of the number of transactions that satisfy the antecedent to the total number of transactions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>consequent_support</code> | The ratio of the number of transactions that satisfy the consequent to the total number of transactions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>number_of_items</code>    | The total number of attributes referenced in the antecedent and consequent of the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

The following example demonstrates an Association model build followed by several invocations of the `GET_ASSOCIATION_RULES` table function:

```
-- prepare a settings table to override default settings
CREATE TABLE market_settings AS
SELECT *
```

```

FROM TABLE(DBMS_DATA_MINING.GET_DEFAULT_SETTINGS)
WHERE setting_name LIKE 'ASSO_%';
BEGIN
-- update the value of the minimum confidence
UPDATE market_settings
SET setting_value = TO_CHAR(0.081)
WHERE setting_name = DBMS_DATA_MINING.asso_min_confidence;

-- build an AR model
DBMS_DATA_MINING.CREATE_MODEL(
  model_name => 'market_model',
  function => DBMS_DATA_MINING.ASSOCIATION,
  data_table_name => 'market_build',
  case_id_column_name => 'item_id',
  target_column_name => NULL,
  settings_table_name => 'market_settings');
END;
/
-- View the (unformatted) rules
SELECT rule_id, antecedent, consequent, rule_support,
       rule_confidence
FROM TABLE(DBMS_DATA_MINING.GET_ASSOCIATION_RULES('market_model'));

```

In the previous example, you view all rules. To view just the top 20 rules, use the following statement.

```

-- View the top 20 (unformatted) rules
SELECT rule_id, antecedent, consequent, rule_support,
       rule_confidence
FROM TABLE(DBMS_DATA_MINING.GET_ASSOCIATION_RULES('market_model', 20));

```

The following query uses the Association model AR\_SH\_SAMPLE, which is created from one of the Oracle Data Mining sample programs:

```

SELECT * FROM TABLE (
  DBMS_DATA_MINING.GET_ASSOCIATION_RULES (
    'AR_SH_SAMPLE', 10, NULL, 0.5, 0.01, 2, 1,
    ORA_MINING_VARCHAR2_NT (
      'NUMBER_OF_ITEMS DESC', 'RULE_CONFIDENCE DESC', 'RULE_SUPPORT DESC'),
    DM_ITEMS(DM_ITEM('CUSTPRODS', 'Mouse Pad', 1, NULL),
              DM_ITEM('CUSTPRODS', 'Standard Mouse', 1, NULL)),
    DM_ITEMS(DM_ITEM('CUSTPRODS', 'Extension Cable', 1, NULL))));

```

The query returns three rules, shown as follows:

```

13  DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Mouse Pad', '= ', 1, NULL, NULL, NULL),
      DM_PREDICATE('CUSTPRODS', 'Standard Mouse', '= ', 1, NULL, NULL, NULL))
    DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Extension Cable', '= ', 1, NULL, NULL, NULL))
    .15532      .84393    2.7075      .18404      .3117    2

11  DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Standard Mouse', '= ', 1, NULL, NULL, NULL))
    DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Extension Cable', '= ', 1, NULL, NULL, NULL))
    .18085      .56291    1.8059      .32128      .3117    1

9   DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Mouse Pad', '= ', 1, NULL, NULL, NULL))
    DM_PREDICATES(
      DM_PREDICATE('CUSTPRODS', 'Extension Cable', '= ', 1, NULL, NULL, NULL))

```

.17766 .55116 1.7682 .32234 .3117 1

## 48.7.21 GET\_FREQUENT\_ITEMSETS Function

The `GET_FREQUENT_ITEMSETS` function returns a set of rows that represent the frequent itemsets from an Association model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

For a detailed description of frequent itemsets, consult *Oracle Data Mining Concepts*.

### Syntax

```
DBMS_DATA_MINING.get_frequent_itemsets(
    model_name IN VARCHAR2,
    topn IN NUMBER DEFAULT NULL,
    max_itemset_length IN NUMBER DEFAULT NULL,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_ItemSets PIPELINED;
```

### Parameters

**Table 48-73 GET\_FREQUENT\_ITEMSETS Function Parameters**

| Parameter                       | Description                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>         | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>topn</code>               | When not <code>NULL</code> , return the top <i>n</i> rows ordered by support in descending order                                    |
| <code>max_itemset_length</code> | Maximum length of an item set.                                                                                                      |
| <code>partition_name</code>     | Specifies a partition in a partitioned model.                                                                                       |

#### Note:

The `partition_name` columns applies only when the model is partitioned.

## Return Values

**Table 48-74 GET\_FREQUENT\_ITEMSETS Function Return Values**

| Return Value | Description                                                                                                                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_ITEMSETS  | A set of rows of type DM_ITEMSET. The rows have the following columns:<br><br><div> <div>(partition_name</div> <div>VARCHAR2(128)</div> </div> <div> <div>itemsets_id</div> <div>NUMBER,</div> </div> <div> <div>items</div> <div>DM_ITEMS,</div> </div> <div> <div>support</div> <div>NUMBER,</div> </div> <div> <div>number_of_items</div> <div>NUMBER)</div> </div> |

### Note:

The partition\_name columns applies only when the model is partitioned.

The items column returns a nested table of type DM\_ITEMS. The rows have type DM\_ITEM:

```
(attribute_name      VARCHAR2(4000),
 attribute_subname   VARCHAR2(4000),
 attribute_num_value NUMBER,
 attribute_str_value VARCHAR2(4000))
```

## Usage Notes

This table function pipes out rows of type DM\_ITEMSETS. For information on Data Mining datatypes and piped output from table functions, see "[Datatypes](#)".

## Examples

The following example demonstrates an Association model build followed by an invocation of GET\_FREQUENT\_ITEMSETS table function from Oracle SQL.

```
-- prepare a settings table to override default settings
CREATE TABLE market_settings AS

    SELECT *

    FROM TABLE(DBMS_DATA_MINING.GET_DEFAULT_SETTINGS)
    WHERE setting_name LIKE 'ASSO_%';
BEGIN
-- update the value of the minimum confidence
UPDATE market_settings
    SET setting_value = TO_CHAR(0.081)
    WHERE setting_name = DBMS_DATA_MINING.asso_min_confidence;

/* build a AR model */
DBMS_DATA_MINING.CREATE_MODEL(
    model_name          => 'market_model',
    function             => DBMS_DATA_MINING.ASSOCIATION,
    data_table_name      => 'market_build',
    case_id_column_name  => 'item_id',
    target_column_name   => NULL,
```

```
settings_table_name => 'market_settings');
END;
/

-- View the (unformatted) Itemsets from SQL*Plus
SELECT itemset_id, items, support, number_of_items
FROM TABLE(DBMS_DATA_MINING.GET_FREQUENT_ITEMSETS('market_model'));
```

In the example above, you view all itemsets. To view just the top 20 itemsets, use the following statement:

```
-- View the top 20 (unformatted) Itemsets from SQL*Plus
SELECT itemset_id, items, support, number_of_items
FROM TABLE(DBMS_DATA_MINING.GET_FREQUENT_ITEMSETS('market_model', 20));
```

## 48.7.22 GET\_MODEL\_COST\_MATRIX Function

The `GET_*` interfaces are replaced by model views, and Oracle recommends that users leverage the views instead. The `GET_MODEL_COST_MATRIX` function is replaced by the `DM$VC` prefixed view, Scoring Cost Matrix. The cost matrix used when building a Decision Tree is made available by the `DM$VM` prefixed view, Decision Tree Build Cost Matrix.

Refer to Model Detail View for Classification Algorithm.

The `GET_MODEL_COST_MATRIX` function returns the rows of a cost matrix associated with the specified model.

By default, this function returns the scoring cost matrix that was added to the model with the `ADD_COST_MATRIX` procedure. If you wish to obtain the cost matrix used to create a model, specify `cost_matrix_type_create` as the `matrix_type`. See [Table 48-75](#).

See also [ADD\\_COST\\_MATRIX Procedure](#).

### Syntax

```
DBMS_DATA_MINING.GET_MODEL_COST_MATRIX (
    model_name          IN VARCHAR2,
    matrix_type         IN VARCHAR2 DEFAULT cost_matrix_type_score)
    partition_name      IN VARCHAR2 DEFAULT NULL);
RETURN DM_COST_MATRIX PIPELINED;
```

### Parameters

**Table 48-75 GET\_MODEL\_COST\_MATRIX Function Parameters**

| Parameter               | Description                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |

**Table 48-75 (Cont.) GET\_MODEL\_COST\_MATRIX Function Parameters**

| Parameter      | Description                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| matrix_type    | The type of cost matrix.<br>COST_MATRIX_TYPE_SCORE — cost matrix used for scoring. (Default.)<br>COST_MATRIX_TYPE_CREATE — cost matrix used to create the model (Decision Tree only). |
| partition_name | Name of the partition in a partitioned model                                                                                                                                          |

### Return Values

**Table 48-76 GET\_MODEL\_COST\_MATRIX Function Return Values**

| Return Value   | Description                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_COST_MATRIX | A set of rows of type DM_COST_ELEMENT. The rows have the following columns:<br><br><div> <div>actual</div> <div>VARCHAR2(4000),</div> <div>NUMBER,</div> <div>predicted</div> <div>VARCHAR2(4000),</div> <div>cost</div> <div>NUMBER)</div> </div> |

### Usage Notes

Only Decision Tree models can be built with a cost matrix. If you want to build a Decision Tree model with a cost matrix, specify the cost matrix table name in the CLAS\_COST\_TABLE\_NAME setting in the settings table for the model. See [Table 48-7](#).

The cost matrix used to create a Decision Tree model becomes the default scoring matrix for the model. If you want to specify different costs for scoring, you can use the REMOVE\_COST\_MATRIX procedure to remove the cost matrix and the ADD\_COST\_MATRIX procedure to add a new one.

The GET\_MODEL\_COST\_MATRIX may return either the build or scoring cost matrix defined for a model or model partition.

If you do not specify a partitioned model name, then an error is displayed.

### Example

This example returns the scoring cost matrix associated with the Naive Bayes model NB\_SH\_CLAS\_SAMPLE.

```
column actual format a10
column predicted format a10
SELECT *
      FROM TABLE(dbms_data_mining.get_model_cost_matrix('nb_sh_clas_sample'))
      ORDER BY predicted, actual;
```

| ACTUAL | PREDICTED | COST |
|--------|-----------|------|
| 0      | 0         | .00  |
| 1      | 0         | .75  |
| 0      | 1         | .25  |
| 1      | 1         | .00  |

## 48.7.23 GET\_MODEL\_DETAILS\_AI Function

The `GET_MODEL_DETAILS_AI` function returns a set of rows that provide the details of an Attribute Importance model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

### Syntax

```
DBMS_DATA_MINING.get_model_details_ai(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN dm_ranked_attributes pipelined;
```

### Parameters

**Table 48-77 GET\_MODEL\_DETAILS\_AI Function Parameters**

| Parameter                   | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>partition_name</code> | Specifies a partition in a partitioned model.                                                                                       |

### Return Values

**Table 48-78 GET\_MODEL\_DETAILS\_AI Function Return Values**

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DM_RANKED_ATTRIBUTES</code> | A set of rows of type <code>DM_RANKED_ATTRIBUTE</code> . The rows have the following columns: <div> <div>(attribute_name</div> <div>attribute_subname</div> <div>importance_value</div> <div>rank</div> </div> <div> <div>VARCHAR2(4000,</div> <div>VARCHAR2(4000),</div> <div>NUMBER,</div> <div>NUMBER(38))</div> </div> |

### Examples

The following example returns model details for the Attribute Importance model `AI_SH_sample`, which was created by the sample program `dmaidemo.sql`. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
SELECT attribute_name, importance_value, rank
FROM TABLE(DBMS_DATA_MINING.GET_MODEL_DETAILS_AI('AI_SH_sample'))
ORDER BY RANK;
```

| ATTRIBUTE_NAME       | IMPORTANCE_VALUE | RANK |
|----------------------|------------------|------|
| HOUSEHOLD_SIZE       | .151685183       | 1    |
| CUST_MARITAL_STATUS  | .145294546       | 2    |
| YRS_RESIDENCE        | .07838928        | 3    |
| AGE                  | .075027496       | 4    |
| Y_BOX_GAMES          | .063039952       | 5    |
| EDUCATION            | .059605314       | 6    |
| HOME_THEATER_PACKAGE | .056458722       | 7    |
| OCCUPATION           | .054652937       | 8    |

|                         |            |    |
|-------------------------|------------|----|
| CUST_GENDER             | .035264741 | 9  |
| BOOKKEEPING_APPLICATION | .019204751 | 10 |
| PRINTER_SUPPLIES        | 0          | 11 |
| OS_DOC_SET_KANJI        | -.00050013 | 12 |
| FLAT_PANEL_MONITOR      | -.00509564 | 13 |
| BULK_PACK_DISKETTES     | -.00540822 | 14 |
| COUNTRY_NAME            | -.01201116 | 15 |
| CUST_INCOME_LEVEL       | -.03951311 | 16 |

## 48.7.24 GET\_MODEL\_DETAILS\_EM Function

The `GET_MODEL_DETAILS_EM` function returns a set of rows that provide statistics about the clusters produced by an Expectation Maximization model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

By default, the EM algorithm groups components into high-level clusters, and `GET_MODEL_DETAILS_EM` returns only the high-level clusters with their hierarchies. Alternatively, you can configure EM model to disable the grouping of components into high-level clusters. In this case, `GET_MODEL_DETAILS_EM` returns the components themselves as clusters with their hierarchies. See [Table 48-12](#).

### Syntax

```
DBMS_DATA_MINING.get_model_details_em(
    model_name VARCHAR2,
    cluster_id  NUMBER    DEFAULT NULL,
    attribute   VARCHAR2  DEFAULT NULL,
    centroid    NUMBER    DEFAULT 1,
    histogram   NUMBER    DEFAULT 1,
    rules       NUMBER    DEFAULT 2,
    attribute_subname VARCHAR2 DEFAULT NULL,
    topn_attributes NUMBER  DEFAULT NULL,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN dm_clusters PIPELINED;
```

### Parameters

**Table 48-79** GET\_MODEL\_DETAILS\_EM Function Parameters

| Parameter               | Description                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.                                                                     |
| <code>cluster_id</code> | The ID of a cluster in the model. When a valid cluster ID is specified, only the details of this cluster are returned. Otherwise, the details for all clusters are returned.                            |
| <code>attribute</code>  | The name of an attribute. When a valid attribute name is specified, only the details of this attribute are returned. Otherwise, the details for all attributes are returned.                            |
| <code>centroid</code>   | This parameter accepts the following values: <ul style="list-style-type: none"> <li>1: Details about centroids are returned (default)</li> <li>0: Details about centroids are not returned</li> </ul>   |
| <code>histogram</code>  | This parameter accepts the following values: <ul style="list-style-type: none"> <li>1: Details about histograms are returned (default)</li> <li>0: Details about histograms are not returned</li> </ul> |

**Table 48-79 (Cont.) GET\_MODEL\_DETAILS\_EM Function Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rules             | This parameter accepts the following values: <ul style="list-style-type: none"> <li>• 2: Details about rules are returned (default)</li> <li>• 1: Rule summaries are returned</li> <li>• 0: No information about rules is returned</li> </ul>                                                                                                                                                                                                                                     |
| attribute_subname | The name of a nested attribute. The full name of a nested attribute has the form:<br><i>attribute_name.attribute_subname</i><br>where <i>attribute_name</i> is the name of the column and <i>attribute_subname</i> is the name of the nested attribute in that column. If the attribute is not nested, then <i>attribute_subname</i> is null.                                                                                                                                     |
| topn_attributes   | Restricts the number of attributes returned in the centroid, histogram, and rules objects. Only the <i>n</i> attributes with the highest confidence values in the rules are returned.<br>If the number of attributes included in the rules is less than <i>topn</i> , then, up to <i>n</i> additional attributes in alphabetical order are returned.<br>If both the <i>attribute</i> and <i>topn_attributes</i> parameters are specified, then <i>topn_attributes</i> is ignored. |
| partition_name    | Specifies a partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

#### Usage Notes

1. For information on Data Mining datatypes and Return Values for Clustering Algorithms piped output from table functions, see "[Datatypes](#)".
2. GET\_MODEL\_DETAILS functions preserve model transparency by automatically reversing the transformations applied during the build process. Thus the attributes returned in the model details are the original attributes (or a close approximation of the original attributes) used to build the model.
3. When cluster statistics are disabled (EMCS\_CLUSTER\_STATISTICS is set to EMCS\_CLUS\_STATS\_DISABLE), GET\_MODEL\_DETAILS\_EM does not return centroids, histograms, or rules. Only taxonomy (hierarchy) and cluster counts are returned.
4. When the partition\_name is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

## 48.7.25 GET\_MODEL\_DETAILS\_EM\_COMP Function

The GET\_MODEL\_DETAILS\_EM\_COMP table function returns a set of rows that provide details about the parameters of an Expectation Maximization model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

#### Syntax

```
DBMS_DATA_MINING.get_model_details_em_comp(
    model_name IN VARCHAR2,
```

```
partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_EM_COMPONENT_SET PIPELINED;
```

## Parameters

**Table 48-80 GET\_MODEL\_DETAILS\_EM\_COMP Function Parameters**

| Parameter      | Description                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------|
| model_name     | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, your own schema is used. |
| partition_name | Specifies a partition in a partitioned model to retrieve details for.                                            |

## Return Values

**Table 48-81 GET\_MODEL\_DETAILS\_EM\_COMP Function Return Values**

| Return Value        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |           |               |              |         |            |         |                |                 |                |                 |                 |                 |       |          |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------------|--------------|---------|------------|---------|----------------|-----------------|----------------|-----------------|-----------------|-----------------|-------|----------|
| DM_EM_COMPONENT_SET | <p>A set of rows of type DM_EM_COMPONENT. The rows have the following columns:</p> <table> <tr> <td>info_type</td><td>VARCHAR2(30),</td></tr> <tr> <td>component_id</td><td>NUMBER,</td></tr> <tr> <td>cluster_id</td><td>NUMBER,</td></tr> <tr> <td>attribute_name</td><td>VARCHAR2(4000),</td></tr> <tr> <td>covariate_name</td><td>VARCHAR2(4000),</td></tr> <tr> <td>attribute_value</td><td>VARCHAR2(4000),</td></tr> <tr> <td>value</td><td>NUMBER )</td></tr> </table> | info_type | VARCHAR2(30), | component_id | NUMBER, | cluster_id | NUMBER, | attribute_name | VARCHAR2(4000), | covariate_name | VARCHAR2(4000), | attribute_value | VARCHAR2(4000), | value | NUMBER ) |

| attribute_name      | VARCHAR2(4000),                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |               |              |         |            |         |                |                 |                |                 |                 |                 |       |          |
| covariate_name      | VARCHAR2(4000),                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |               |              |         |            |         |                |                 |                |                 |                 |                 |       |          |
| attribute_value     | VARCHAR2(4000),                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |               |              |         |            |         |                |                 |                |                 |                 |                 |       |          |
| value               | NUMBER )                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |           |               |              |         |            |         |                |                 |                |                 |                 |                 |       |          |

## Usage Notes

1. This table function pipes out rows of type DM\_EM\_COMPONENT. For information on Data Mining datatypes and piped output from table functions, see ["Datatypes"](#).

The columns in each row returned by GET\_MODEL\_DETAILS\_EM\_COMP are described as follows:

| Column in DM_EM_COMPONENT | Description                                                                                                                                                                                                                                            |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| info_type                 | <p>The type of information in the row. The following information types are supported:</p> <ul style="list-style-type: none"> <li>• cluster</li> <li>• prior</li> <li>• mean</li> <li>• covariance</li> <li>• frequency</li> </ul>                      |
| component_id              | Unique identifier of a component                                                                                                                                                                                                                       |
| cluster_id                | Unique identifier of the high-level leaf cluster for each component                                                                                                                                                                                    |
| attribute_name            | <p>Name of an original attribute or a derived feature ID. The derived feature ID is used in models built on data with nested columns. The derived feature definitions can be obtained from the <a href="#">GET_MODEL_DETAILS_EM_PROJ Function</a>.</p> |

| Column in DM_EM_COMPONENT | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| covariate_name            | Name of an original attribute or a derived feature ID used in variance/covariance definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| attribute_value           | Categorical value or bin interval for binned numerical attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| value                     | <p>Encodes different information depending on the value of info_type, as follows:</p> <ul style="list-style-type: none"> <li>cluster — The value field is NULL</li> <li>prior — The value field returns the component prior</li> <li>mean — The value field returns the mean of the attribute specified in attribute_name</li> <li>covariance — The value field returns the covariance of the attributes specified in attribute_name and covariate_name. Using the same attribute in attribute_name and covariate_name, returns the variance.</li> <li>frequency — The value field returns the multivalued Bernoulli frequency parameter for the attribute/value combination specified by attribute_name and attribute_value</li> </ul> <p>See Usage Note 2 for details.</p> |

2. The following table shows which fields are used for each info\_type. The blank cells represent NULLs.

| info_type  | component_id | cluster_id | attribute_name | covariate_name | attribute_value | value |
|------------|--------------|------------|----------------|----------------|-----------------|-------|
| cluster    | X            | X          |                |                |                 |       |
| prior      | X            | X          |                |                |                 | X     |
| mean       | X            | X          | X              |                |                 | X     |
| covariance | X            | X          | X              | X              |                 | X     |
| frequency  | X            | X          | X              |                | X               | X     |

3. GET\_MODEL\_DETAILS functions preserve model transparency by automatically reversing the transformations applied during the build process. Thus the attributes returned in the model details are the original attributes (or a close approximation of the original attributes) used to build the model.
4. When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

## 48.7.26 GET\_MODEL\_DETAILS\_EM\_PROJ Function

The GET\_MODEL\_DETAILS\_EM\_PROJ function returns a set of rows that provide statistics about the projections produced by an Expectation Maximization model. Starting from Oracle

Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

## Syntax

```
DBMS_DATA_MINING.get_model_details_em_proj(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_EM_PROJECTION_SET PIPELINED;
```

## Parameters

**Table 48-82 GET\_MODEL\_DETAILS\_EM\_PROJ Function Parameters**

| Parameter      | Description                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| model_name     | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, then your own schema is used. |
| partition_name | Specifies a partition in a partitioned model                                                                          |

## Return Values

**Table 48-83 GET\_MODEL\_DETAILS\_EM\_PROJ Function Return Values**

| Return Value         | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                 |                |                 |                   |                 |                 |                 |             |          |

| attribute_value      | VARCHAR2(4000),                                                                                                                                                                                                                                                                                                                                                                                                                    |              |                 |                |                 |                   |                 |                 |                 |             |          |
| coefficient          | NUMBER )                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                 |                |                 |                   |                 |                 |                 |             |          |

## Usage Notes

1. This table function pipes out rows of type DM\_EM\_PROJECTION. For information on Data Mining datatypes and piped output from table functions, see "[Datatypes](#)".

The columns in each row returned by GET\_MODEL\_DETAILS\_EM\_PROJ are described as follows:

| Column in DM_EM_PROJECTION | Description                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| feature_name               | Name of a derived feature. The feature maps to the attribute_name returned by the <a href="#">GET_MODEL_DETAILS_EM Function</a> . |
| attribute_name             | Name of a column in the build data                                                                                                |
| attribute_subname          | Subname in a nested column                                                                                                        |
| attribute_value            | Categorical value                                                                                                                 |
| coefficient                | Projection coefficient. The representation is sparse; only the non-zero coefficients are returned.                                |

2. `GET_MODEL_DETAILS` functions preserve model transparency by automatically reversing the transformations applied during the build process. Thus the attributes returned in the model details are the original attributes (or a close approximation of the original attributes) used to build the model.

The coefficients are related to the transformed, not the original, attributes. When returned directly with the model details, the coefficients may not provide meaningful information.

3. When the value is `NULL` for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

## 48.7.27 GET\_MODEL\_DETAILS\_GLM Function

The `GET_MODEL_DETAILS_GLM` function returns the coefficient statistics for a Generalized Linear Model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

The same set of statistics is returned for both linear and Logistic Regression, but statistics that do not apply to the mining function are returned as `NULL`. For more details, see the Usage Notes.

#### Syntax

```
DBMS_DATA_MINING.get_model_details_glm(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_GLM_Coeff_Set PIPELINED;
```

#### Parameters

**Table 48-84 GET\_MODEL\_DETAILS\_GLM Function Parameters**

| Parameter                   | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>partition_name</code> | Specifies a partition in a partitioned model                                                                                        |

## Return Values

**Table 48-85 GET\_MODEL\_DETAILS\_GLM Return Values**

| Return Value          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                 |                |                 |                   |                 |                 |                 |                    |                 |             |         |           |         |                |         |         |         |     |         |                 |         |                   |         |                   |         |                 |                |                       |                |                       |                |

GET\_MODEL\_DETAILS\_GLM returns a row of statistics for each attribute and one extra row for the intercept, which is identified by a null value in the attribute name. Each row has the DM\_GLM\_COEFF datatype. The statistics are described in [Table 48-86](#).

**Table 48-86 DM\_GLM\_COEFF Datatype Description**

| Column            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| class             | <p>The non-reference target class for Logistic Regression. The model is built to predict the probability of this class.</p> <p>The other class (the reference class) is specified in the model setting GLMS_REFERENCE_CLASS_NAME. See <a href="#">Table 48-18</a>.</p> <p>For Linear Regression, class is null.</p>                                                                                                                                 |
| attribute_name    | <p>The attribute name when there is no subname, or first part of the attribute name when there is a subname. The value of attribute_name is also the name of the column in the case table that is the source for this attribute.</p> <p>For the intercept, attribute_name is null. Intercepts are equivalent to the bias term in SVM models.</p>                                                                                                    |
| attribute_subname | <p>The name of an attribute in a nested table. The full name of a nested attribute has the form:</p> <p><i>attribute_name.attribute_subname</i></p> <p>where attribute_name is the name of the nested column in the case table that is the source for this attribute.</p> <p>If the attribute is not nested, then attribute_subname is null. If the attribute is an intercept, then both the attribute_name and the attribute_subname are null.</p> |

**Table 48-86 (Cont.) DM\_GLM\_COEFF Datatype Description**

| Column                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| attribute_value       | The value of the attribute (categorical attribute only).<br>For numeric attributes, attribute_value is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| feature_expression    | The feature name constructed by the algorithm when feature generation is enabled and higher-order features are found. If feature selection is not enabled, then the feature name is simply the fully-qualified attribute name (attribute_name.attribute_subname if the attribute is in a nested column).<br>For categorical attributes, the algorithm constructs a feature name that has the following form:<br><i>fully-qualified_attribute_name.attribute_value</i><br>For numeric attributes, the algorithm constructs a name for the higher-order feature by taking the product of the resulting values:<br><i>(attrib1)*(attrib2))*.....</i><br>where attrib1 and attrib2 are fully-qualified attribute names. |
| coefficient           | The linear coefficient estimate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| std_error             | Standard error of the coefficient estimate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| test_statistic        | For Linear Regression, the t-value of the coefficient estimate.<br>For Logistic Regression, the Wald chi-square value of the coefficient estimate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| p-value               | Probability of the test_statistic. Used to analyze the significance of specific attributes in the model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| VIF                   | Variance Inflation Factor. The value is zero for the intercept. For Logistic Regression, VIF is null. VIF is not computed if the solver is Cholesky.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| std_coefficient       | Standardized estimate of the coefficient.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| lower_coeff_limit     | Lower confidence bound of the coefficient.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| upper_coeff_limit     | Upper confidence bound of the coefficient.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| exp_coefficient       | Exponentiated coefficient for Logistic Regression. For Linear Regression, exp_coefficient is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| exp_lower_coeff_limit | Exponentiated coefficient for lower confidence bound of the coefficient for Logistic Regression. For Linear Regression, exp_lower_coeff_limit is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| exp_upper_coeff_limit | Exponentiated coefficient for upper confidence bound of the coefficient for Logistic Regression. For Linear Regression, exp_lower_coeff_limit is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Usage Notes

Not all statistics are necessarily returned for each coefficient. Statistics will be null if:

- They do not apply to the mining function. For example, exp\_coefficient does not apply to Linear Regression.
- They cannot be computed from a theoretical standpoint. For information on ridge regression, see [Table 48-18](#).
- They cannot be computed because of limitations in system resources.

- Their values would be infinity.
- When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

### Examples

The following example returns some of the model details for the GLM Regression model GLMR\_SH\_Regr\_sample, which was created by the sample program dmglrdem.sql. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
SET line 120
SET pages 99
column attribute_name format a30
column attribute_subname format a20
column attribute_value format a20
col coefficient format 990.9999
col std_error format 990.9999
SQL> SELECT * FROM
(SELECT attribute_name, attribute_value, coefficient, std_error
 FROM DM$VDGLMR_SH_REGR_SAMPLE order by 1,2)
WHERE rownum < 11;
```

## 48.7.28 GET\_MODEL\_DETAILS\_GLOBAL Function

The GET\_MODEL\_DETAILS\_GLOBAL function returns statistics about the model as a whole. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

Global details are available for Generalized Linear Models, Association Rules, Singular Value Decomposition, and Expectation Maximization. There are new Global model views which show global information for all algorithms. Oracle recommends that users leverage the views instead. Refer to Model Details View Global.

### Syntax

```
DBMS_DATA_MINING.get_model_details_global(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_model_global_details PIPELINED;
```

## Parameters

**Table 48-87 GET\_MODEL\_DETAILS\_GLOBAL Function Parameters**

| Parameter      | Description                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| model_name     | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, then your own schema is used. |
| partition_name | Specifies a partition in a partitioned model.                                                                         |

## Return Values

**Table 48-88 GET\_MODEL\_DETAILS\_GLOBAL Function Return Values**

| Return Value            | Description                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_MODEL_GLOBAL_DETAILS | A collection of rows of type DM_MODEL_GLOBAL_DETAIL. The rows have the following columns:<br><br>(global_detail_name    VARCHAR2(30),<br>global_detail_value    NUMBER) |

## Examples

The following example returns the global model details for the GLM Regression model GLMR\_SH\_Regr\_sample, which was created by the sample program dmglrdem.sql. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
SELECT *
  FROM TABLE(dbms_data_mining.get_model_details_global(
    'GLMR_SH_Regr_sample'))
ORDER BY global_detail_name;

## 48.7.29 GET\_MODEL\_DETAILS\_KM Function

The `GET_MODEL_DETAILS_KM` function returns a set of rows that provide the details of a *k*-Means clustering model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

You can provide input to `GET_MODEL_DETAILS_KM` to request specific information about the model, thus improving the performance of the query. If you do not specify filtering parameters, then `GET_MODEL_DETAILS_KM` returns all the information about the model.

## Syntax

```
DBMS_DATA_MINING.get_model_details_km(
    model_name VARCHAR2,
    cluster_id NUMBER    DEFAULT NULL,
    attribute  VARCHAR2 DEFAULT NULL,
    centroid  NUMBER    DEFAULT 1,
    histogram NUMBER    DEFAULT 1,
    rules     NUMBER    DEFAULT 2,
    attribute_subname VARCHAR2 DEFAULT NULL,
    topn_attributes NUMBER DEFAULT NULL,
    partition_name VARCHAR2 DEFAULT NULL)
RETURN dm_clusters PIPELINED;
```

## Parameters

**Table 48-89 GET\_MODEL\_DETAILS\_KM Function Parameters**

| Parameter               | Description                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.                                                                                                           |
| <code>cluster_id</code> | The ID of a cluster in the model. When a valid cluster ID is specified, only the details of this cluster are returned. Otherwise the details for all clusters are returned.                                                                   |
| <code>attribute</code>  | The name of an attribute. When a valid attribute name is specified, only the details of this attribute are returned. Otherwise, the details for all attributes are returned                                                                   |
| <code>centroid</code>   | This parameter accepts the following values: <ul style="list-style-type: none"> <li>• 1: Details about centroids are returned (default)</li> <li>• 0: Details about centroids are not returned</li> </ul>                                     |
| <code>histogram</code>  | This parameter accepts the following values: <ul style="list-style-type: none"> <li>• 1: Details about histograms are returned (default)</li> <li>• 0: Details about histograms are not returned</li> </ul>                                   |
| <code>rules</code>      | This parameter accepts the following values: <ul style="list-style-type: none"> <li>• 2: Details about rules are returned (default)</li> <li>• 1: Rule summaries are returned</li> <li>• 0: No information about rules is returned</li> </ul> |

**Table 48-89 (Cont.) GET\_MODEL\_DETAILS\_KM Function Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| attribute_subname | The name of a nested attribute. The full name of a nested attribute has the form:<br><i>attribute_name.attribute_subname</i><br>where <i>attribute_name</i> is the name of the column and <i>attribute_subname</i> is the name of the nested attribute in that column.<br>If the attribute is not nested, attribute_subname is null.                                                                                                                        |
| topn_attributes   | Restricts the number of attributes returned in the centroid, histogram, and rules objects. Only the <i>n</i> attributes with the highest confidence values in the rules are returned.<br>If the number of attributes included in the rules is less than <i>topn</i> , then up to <i>n</i> additional attributes in alphabetical order are returned.<br>If both the attribute and topn_attributes parameters are specified, then topn_attributes is ignored. |
| partition_name    | Specifies a partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                               |

### Usage Notes

1. The table function pipes out rows of type `DM_CLUSTERS`. For information on Data Mining datatypes and Return Value for Clustering Algorithms piped output from table functions, see "Datatypes".
2. When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

### Examples

The following example returns model details for the *k*-Means clustering model `KM_SH_Clus_sample`, which was created by the sample program `dmkmdemo.sql`. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
SELECT T.id          clu_id,
       T.record_count rec_cnt,
       T.parent       parent,
       T.tree_level   tree_level,
       T.dispersion   dispersion
FROM (SELECT *
      FROM TABLE(DBMS_DATA_MINING.GET_MODEL_DETAILS_KM(
                    'KM_SH_Clus_sample'))
      ORDER BY id) T
WHERE ROWNUM < 6;
```

| CLU_ID | REC_CNT | PARENT | TREE_LEVEL | DISPERSION |
|--------|---------|--------|------------|------------|
| 1      | 1500    |        | 1          | 5.9152211  |
| 2      | 638     | 1      | 2          | 3.98458982 |
| 3      | 862     | 1      | 2          | 5.83732097 |
| 4      | 376     | 3      | 3          | 5.05192137 |
| 5      | 486     | 3      | 3          | 5.42901522 |

## 48.7.30 GET\_MODEL\_DETAILS\_NB Function

The `GET_MODEL_DETAILS_NB` function returns a set of rows that provide the details of a Naive Bayes model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

### Syntax

```
DBMS_DATA_MINING.get_model_details_nb(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_NB_Details PIPELINED;
```

### Parameters

**Table 48-90 GET\_MODEL\_DETAILS\_NB Function Parameters**

| Parameter                   | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>partition_name</code> | Specifies a partition in a partitioned model                                                                                        |

### Return Values

**Table 48-91 GET\_MODEL\_DETAILS\_NB Function Return Values**

| Return Value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                    |                             |                                         |                               |                                         |                       |                                |                       |                           |                                |                             |                               |                                |                               |                                  |                               |                                  |                       |                                      |                       |

### Usage Notes

- The table function pipes out rows of type `DM_NB_DETAILS`. For information on Data Mining datatypes and piped output from table functions, see "[Datatypes](#)".
- When the value is `NULL` for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

## Examples

The following query is from the sample program `dmnbdemo.sql`. It returns model details about the model `NB_SH_Clas_sample`. For information about the sample programs, see *Oracle Data Mining User's Guide*.

The query creates labels from the bin boundary tables that were used to bin the training data. It replaces the attribute values with the labels. For numeric bins, the labels are `(lower_boundary,upper_boundary]`; for categorical bins, the label matches the value it represents. (This method of categorical label representation will only work for cases where one value corresponds to one bin.) The target was not binned.

```
WITH
  bin_label_view AS (
    SELECT col, bin, (DECODE(bin,'1','(',') || lv || ',' || val || ']') label
      FROM (SELECT col,
                   bin,
                   LAST_VALUE(val) OVER (
                     PARTITION BY col ORDER BY val
                     ROWS BETWEEN UNBOUNDED PRECEDING AND 1 PRECEDING) lv,
                   val
            FROM nb_sh_sample_num)
    UNION ALL
    SELECT col, bin, val label
      FROM nb_sh_sample_cat
  ),

## 48.7.31 GET\_MODEL\_DETAILS\_NMF Function

The `GET_MODEL_DETAILS_NMF` function returns a set of rows that provide the details of a Non-Negative Matrix Factorization model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

### Syntax

```
DBMS_DATA_MINING.get_model_details_nmf(
    model_name IN VARCHAR2,
    partition_name VARCHAR2 DEFAULT NULL)
RETURN DM_NMF_Feature_Set PIPELINED;
```

### Parameters

**Table 48-92 GET\_MODEL\_DETAILS\_NMF Function Parameters**

| Parameter                   | Description                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |
| <code>partition_name</code> | Specifies a partition in a partitioned model                                                                                        |

### Return Values

**Table 48-93 GET\_MODEL\_DETAILS\_NMF Function Return Values**

| Return Value                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                          |                      |                                |                              |                            |                                    |                              |                              |                                |                              |                              |                              |                          |                      |

### Usage Notes

- The table function pipes out rows of type `DM_NMF_FEATURE_SET`. For information on Data Mining datatypes and piped output from table functions, see "Datatypes".
- When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

### Examples

The following example returns model details for the feature extraction model `NMF_SH_Sample`, which was created by the sample program `dmnmdemo.sql`. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
SELECT * FROM (
SELECT F.feature_id,
      A.attribute_name,
      A.attribute_value,
      A.coefficient
  FROM TABLE(DBMS_DATA_MINING.GET_MODEL_DETAILS_NMF('NMF_SH_Sample')) F,
       TABLE(F.attribute_set) A
 ORDER BY feature_id,attribute_name,attribute_value

## 48.7.32 GET\_MODEL\_DETAILS\_OC Function

The `GET_MODEL_DETAILS_OC` function returns a set of rows that provide the details of an O-Cluster clustering model. The rows are an enumeration of the Clustering patterns generated during the creation of the model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

You can provide input to `GET_MODEL_DETAILS_OC` to request specific information about the model, thus improving the performance of the query. If you do not specify filtering parameters, then `GET_MODEL_DETAILS_OC` returns all the information about the model.

### Syntax

```
DBMS_DATA_MINING.get_model_details_oc(
  model_name VARCHAR2,
  cluster_id  NUMBER   DEFAULT NULL,
  attribute   VARCHAR2 DEFAULT NULL,
  centroid    NUMBER   DEFAULT 1,
  histogram   NUMBER   DEFAULT 1,
  rules       NUMBER   DEFAULT 2,
  topn_attributes NUMBER DEFAULT NULL,
  partition_name VARCHAR2 DEFAULT NULL)
RETURN dm_clusters PIPELINED;
```

### Parameters

**Table 48-94 GET\_MODEL\_DETAILS\_OC Function Parameters**

| Parameter               | Description                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |

**Table 48-94 (Cont.) GET\_MODEL\_DETAILS\_OC Function Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster_id      | The ID of a cluster in the model. When a valid cluster ID is specified, only the details of this cluster are returned. Otherwise the details for all clusters are returned.                                                                                                                                                                                                                                                                                                              |
| attribute       | The name of an attribute. When a valid attribute name is specified, only the details of this attribute are returned. Otherwise, the details for all attributes are returned                                                                                                                                                                                                                                                                                                              |
| centroid        | This parameter accepts the following values: <ul style="list-style-type: none"> <li>1: Details about centroids are returned (default)</li> <li>0: Details about centroids are not returned</li> </ul>                                                                                                                                                                                                                                                                                    |
| histogram       | This parameter accepts the following values: <ul style="list-style-type: none"> <li>1: Details about histograms are returned (default)</li> <li>0: Details about histograms are not returned</li> </ul>                                                                                                                                                                                                                                                                                  |
| rules           | This parameter accepts the following values: <ul style="list-style-type: none"> <li>2: Details about rules are returned (default)</li> <li>1: Rule summaries are returned</li> <li>0: No information about rules is returned</li> </ul>                                                                                                                                                                                                                                                  |
| topn_attributes | Restricts the number of attributes returned in the centroid, histogram, and rules objects. Only the <i>n</i> attributes with the highest confidence values in the rules are returned.<br><br>If the number of attributes included in the rules is less than <i>topn</i> , then up to <i>n</i> additional attributes in alphabetical order are returned.<br><br>If both the <i>attribute</i> and <i>topn_attributes</i> parameters are specified, then <i>topn_attributes</i> is ignored. |
| partition_name  | Specifies a partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Usage Notes

- For information about Data Mining datatypes and Return Values for Clustering Algorithms piped output from table functions, see "[Datatypes](#)".
- When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

### Examples

The following example returns model details for the clustering model `OC_SH_Clus_sample`, which was created by the sample program `dmocdemo.sql`. For information about the sample programs, see *Oracle Data Mining User's Guide*.

For each cluster in this example, the split predicate indicates the attribute and the condition used to assign records to the cluster's children during model build. It provides an important piece of information on how the population within a cluster can be divided up into two smaller clusters.

```
SELECT clu_id, attribute_name, op, s_value
FROM (SELECT a.id clu_id, sp.attribute_name, sp.conditional_operator op,
            sp.attribute_str_value s_value
      FROM TABLE(DBMS_DATA_MINING.GET_MODEL_DETAILS_OC(
                    'OC_SH_Clus_sample')) a,
      TABLE(a.split_predicate) sp
     ORDER BY a.id, op, s_value)
```

WHERE ROWNUM < 11;

| CLU_ID | ATTRIBUTE_NAME | OP S_VALUE |
|--------|----------------|------------|
| 1      | OCCUPATION     | IN ?       |
| 1      | OCCUPATION     | IN Armed-F |
| 1      | OCCUPATION     | IN Cleric. |
| 1      | OCCUPATION     | IN Crafts  |
| 2      | OCCUPATION     | IN ?       |
| 2      | OCCUPATION     | IN Armed-F |
| 2      | OCCUPATION     | IN Cleric. |
| 3      | OCCUPATION     | IN Exec.   |
| 3      | OCCUPATION     | IN Farming |
| 3      | OCCUPATION     | IN Handler |

## 48.7.33 GET\_MODEL\_SETTINGS Function

The `GET_MODEL_SETTINGS` function returns the settings used to build the given model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Static Data Dictionary Views: `ALL_ALL_TABLES` to `ALL_OUTLINES`" in *Oracle Database Reference*.

### Syntax

```
FUNCTION get_model_settings(model_name IN VARCHAR2)
RETURN DM_Model_Settings PIPELINED;
```

### Parameters

**Table 48-95 GET\_MODEL\_SETTINGS Function Parameters**

| Parameter               | Description                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |

### Return Values

**Table 48-96 GET\_MODEL\_SETTINGS Function Return Values**

| Return Value                   | Description                                                                                                                                                                                                                                                                                                                   |      |      |              |              |               |                |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------|--------------|--------------|---------------|----------------|
| <code>DM_MODEL_SETTINGS</code> | <p>A set of rows of type <code>DM_MODEL_SETTINGS</code>. The rows have the following columns:</p> <pre>DM_MODEL_SETTINGS TABLE OF SYS.DM_MODEL_SETTING</pre> <table> <tr> <th>Name</th><th>Type</th></tr> <tr><td>SETTING_NAME</td><td>VARCHAR2(30)</td></tr> <tr><td>SETTING_VALUE</td><td>VARCHAR2(4000)</td></tr> </table> | Name | Type | SETTING_NAME | VARCHAR2(30) | SETTING_VALUE | VARCHAR2(4000) |
| Name                           | Type                                                                                                                                                                                                                                                                                                                          |      |      |              |              |               |                |
| SETTING_NAME                   | VARCHAR2(30)                                                                                                                                                                                                                                                                                                                  |      |      |              |              |               |                |
| SETTING_VALUE                  | VARCHAR2(4000)                                                                                                                                                                                                                                                                                                                |      |      |              |              |               |                |

## Usage Notes

1. This table function pipes out rows of type `DM_MODEL_SETTINGS`. For information on Data Mining datatypes and piped output from table functions, see "[DBMS\\_DATA\\_MINING Datatypes](#)".
2. The setting names/values include both those specified by the user and any defaults assigned by the build process.

## Examples

The following example returns model settings for an example Naive Bayes model.

| SETTING_NAME                 | SETTING_VALUE           |
|------------------------------|-------------------------|
| ALGO_NAME                    | ALGO_NAIVE_BAYES        |
| PREP_AUTO                    | ON                      |
| ODMS_MAX_PARTITIONS          | 1000                    |
| NABS_SINGLETON_THRESHOLD     | 0                       |
| CLAS_WEIGHTS_BALANCED        | OFF                     |
| NABS_PAIRWISE_THRESHOLD      | 0                       |
| ODMS_PARTITION_COLUMNS       | GENDER,Y_BOX_GAMES      |
| ODMS_MISSING_VALUE_TREATMENT | ODMS_MISSING_VALUE_AUTO |
| ODMS_SAMPLING                | ODMS_SAMPLING_DISABLE   |

9 rows selected.

## 48.7.34 GET\_MODEL\_SIGNATURE Function

The `GET_MODEL_SIGNATURE` function returns the list of columns from the build input table that were used by the build process to train the model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Static Data Dictionary Views: `ALL_ALL_TABLES` to `ALL_OUTLINES`" in *Oracle Database Reference*.

## Syntax

```
FUNCTION get_model_signature (model_name IN VARCHAR2)
RETURN DM_Model_Signature PIPELINED;
```

## Parameters

**Table 48-97 GET\_MODEL\_SIGNATURE Function Parameters**

| Parameter               | Description                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name].model_name</code> . If you do not specify a schema, then your own schema is used. |

## Return Values

**Table 48-98 GET\_MODEL\_SIGNATURE Function Return Values**

| Return Value       | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_MODEL_SIGNATURE | <p>A set of rows of type DM_MODEL_SIGNATURE. The rows have the following columns:</p> <pre> DM_MODEL_SIGNATURE TABLE OF SYS.DM_MODEL_SIGNATURE_ATTRIBUTE       Name                                Type       -----                                -----       ATTRIBUTE_NAME                      VARCHAR2(130)       ATTRIBUTE_TYPE                      VARCHAR2(106) </pre> |

## Usage Notes

1. This table function pipes out rows of type DM\_MODEL\_SIGNATURE. For information on Data Mining datatypes and piped output from table functions, see "[DBMS\\_DATA\\_MINING Datatypes](#)".
2. The signature names or types include only those attributes used by the build process.

## Examples

The following example returns model settings for an example Naive Bayes model.

| ATTRIBUTE_NAME           | ATTRIBUTE_TYPE |
|--------------------------|----------------|
| AGE                      | NUMBER         |
| ANNUAL_INCOME            | NUMBER         |
| AVERAGE_ITEMS_PURCHASED  | NUMBER         |
| BOOKKEEPING_APPLICATION  | NUMBER         |
| BULK_PACK_DISKETTES      | NUMBER         |
| BULK_PURCH_AVE_AMT       | NUMBER         |
| DISABLE_COOKIES          | NUMBER         |
| EDUCATION                | VARCHAR2       |
| FLAT_PANEL_MONITOR       | NUMBER         |
| GENDER                   | VARCHAR2       |
| HOME_THEATER_PACKAGE     | NUMBER         |
| HOUSEHOLD_SIZE           | VARCHAR2       |
| MAILING_LIST             | NUMBER         |
| MARITAL_STATUS           | VARCHAR2       |
| NO_DIFFERENT_KIND_ITEMS  | NUMBER         |
| OCCUPATION               | VARCHAR2       |
| OS_DOC_SET_KANJI         | NUMBER         |
| PETS                     | NUMBER         |
| PRINTER_SUPPLIES         | NUMBER         |
| PROMO_RESPOND            | NUMBER         |
| SHIPPING_ADDRESS_COUNTRY | VARCHAR2       |
| SR_CITIZEN               | NUMBER         |
| TOP_REASON_FOR_SHOPPING  | VARCHAR2       |
| WKS_SINCE_LAST_PURCH     | NUMBER         |
| WORKCLASS                | VARCHAR2       |
| YRS_RESIDENCE            | NUMBER         |
| Y_BOX_GAMES              | NUMBER         |

## 48.7.35 GET\_MODEL\_DETAILS\_SVD Function

The `GET_MODEL_DETAILS_SVD` function returns a set of rows that provide the details of a Singular Value Decomposition model. Oracle recommends to use model details view settings. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

Refer to Model Details View for Singular Value Decomposition.

## Syntax

```
DBMS_DATA_MINING.get_model_details_svd(
    model_name IN VARCHAR2,
    matrix_type IN VARCHAR2 DEFAULT NULL,
    partition_name VARCHAR2 DEFAULT NULL)
RETURN DM_SVD_MATRIX_Set PIPELINED;
```

## Parameters

**Table 48-99 GET\_MODEL\_DETAILS\_SVD Function Parameters**

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.                                                                                                                                                                                                                                                                                                                            |
| <code>matrix_type</code>    | Specifies which of the three SVD matrix types to return. Values are: U, S, V, and NULL. When <code>matrix_type</code> is null (default), all matrices are returned.<br><br>The U matrix is only computed when the <code>SVDS_U_MATRIX_OUTPUT</code> setting is enabled. It is not computed by default. If the model does not contain U matrices and you set <code>matrix_type</code> to U, an empty set of rows is returned. See <a href="#">Table 48-26</a> . |
| <code>partition_name</code> | A partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Return Values

**Table 48-100 GET\_MODEL\_DETAILS\_SVD Function Return Values**

| Return Value                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                           |                       |                         |                      |                                |                              |                             |                              |                                |                              |                      |                              |                    |                      |                       |                      |                               |                      |

## Usage Notes

1. This table function pipes out rows of type `DM_SVD_MATRIX`. For information on Data Mining datatypes and piped output from table functions, see "[Datatypes](#)".

The columns in each row returned by `GET_MODEL_DETAILS_SVD` are described as follows:

| Column in <code>DM_SVD_MATRIX_SET</code> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>matrix_type</code>                 | The type of matrix. Possible values are <b>S</b> , <b>V</b> , and <b>U</b> . This field is never null.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>feature_id</code>                  | The feature that the matrix entry refers to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>mapped_feature_id</code>           | A descriptive name for the feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>attribute_name</code>              | Column name in the <b>V</b> matrix component bases. This field is null for the <b>S</b> and <b>U</b> matrices.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>attribute_subname</code>           | Subname in the <b>V</b> matrix component bases. This is relevant only in the case of a nested column. This field is null for the <b>S</b> and <b>U</b> matrices.                                                                                                                                                                                                                                                                                                                                                           |
| <code>case_id</code>                     | Unique identifier of the row in the build data described by the <b>U</b> matrix projection. This field is null for the <b>S</b> and <b>V</b> matrices.                                                                                                                                                                                                                                                                                                                                                                     |
| <code>value</code>                       | The matrix entry value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>variance</code>                    | The variance explained by a component. It is non-null only for <b>S</b> matrix entries. This column is non-null only for <b>S</b> matrix entries and for SVD models with setting <code>dbms_data_mining.svds_scoring_mode</code> set to <code>dbms_data_mining.svds_scoring_pca</code> and the build data is centered, either manually or because the setting <code>dbms_data_mining.prep_auto</code> is set to <code>dbms_data_mining.prep_auto_on</code> .                                                               |
| <code>pct_cum_variance</code>            | The percent cumulative variance explained by the components thus far. The components are ranked by the explained variance in descending order.<br><br>This column is non-null only for <b>S</b> matrix entries and for SVD models with setting <code>dbms_data_mining.svds_scoring_mode</code> set to <code>dbms_data_mining.svds_scoring_pca</code> and the build data is centered, either manually or because the setting <code>dbms_data_mining.prep_auto</code> is set to <code>dbms_data_mining.prep_auto_on</code> . |

2. The output of `GET_MODEL_DETAILS` is in sparse format. Zero values are not returned. Only the diagonal elements of the **S** matrix, the non-zero coefficients in the **V** matrix bases, and the non-zero **U** matrix projections are returned.

There is one exception: If the data row does not produce non-zero **U** Matrix projections, the case ID for that row is returned with `NULL` for the `feature_id` and `value`. This is done to avoid losing any records from the original data.

3. `GET_MODEL_DETAILS` functions preserve model transparency by automatically reversing the transformations applied during the build process. Thus the attributes returned in the model details are the original attributes (or a close approximation of the original attributes) used to build the model.
4. When the value is `NULL` for a partitioned model, an exception is thrown. When the value is not null, it must contain the preferred partition name.

## 48.7.36 GET\_MODEL\_DETAILS\_SVM Function

The `GET_MODEL_DETAILS_SVM` function returns a set of rows that provide the details of a linear Support Vector Machine (SVM) model. If invoked for nonlinear SVM, it returns `ORA-40215`. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Model Detail Views" in *Oracle Data Mining User's Guide*.

In linear SVM models, only nonzero coefficients are stored. This reduces storage and speeds up model loading. As a result, if an attribute is missing in the coefficient list returned by `GET_MODEL_DETAILS_SVM`, then the coefficient of this attribute should be interpreted as zero.

## Syntax

```
DBMS_DATA_MINING.get_model_details_svm(
    model_name    VARCHAR2,
    reverse_coef  NUMBER DEFAULT 0,
    partition_name VARCHAR2 DEFAULT NULL)
RETURN DM_SVM_Linear_Coeff_Set PIPELINED;
```

## Parameters

**Table 48-101** GET\_MODEL\_DETAILS\_SVM Function Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code>     | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>reverse_coef</code>   | Whether or not <code>GET_MODEL_DETAILS_SVM</code> should transform the attribute coefficients using the original attribute transformations.<br><br>When <code>reverse_coef</code> is set to 0 (default), <code>GET_MODEL_DETAILS_SVM</code> returns the coefficients directly from the model without applying transformations.<br><br>When <code>reverse_coef</code> is set to 1, <code>GET_MODEL_DETAILS_SVM</code> transforms the coefficients and bias by applying the normalization shifts and scales that were generated using automatic data preparation.<br><br>See Usage Note 4. |
| <code>partition_name</code> | Specifies a partition in a partitioned model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Return Values

**Table 48-102 GET\_MODEL\_DETAILS\_SVM Function Return Values**

| Return Value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DM_SVM_LINEAR_COEFF_SET | <p>A set of rows of type DM_SVM_LINEAR_COEFF. The rows have the following columns:</p> <pre>(class          VARCHAR2(4000),  attribute_set   DM_SVM_ATTRIBUTE_SET)</pre> <p>The attribute_set column returns a nested table of type DM_SVM_ATTRIBUTE_SET. The rows, of type DM_SVM_ATTRIBUTE, have the following columns:</p> <pre>(attribute_name  VARCHAR2(4000),  attribute_subname VARCHAR2(4000),  attribute_value  VARCHAR2(4000),  coefficient      NUMBER)</pre> <p>See Usage Notes.</p> |

## Usage Notes

1. This table function pipes out rows of type DM\_SVM\_LINEAR\_COEFF. For information on Data Mining datatypes and piped output from table functions, see ["Datatypes"](#).
2. The class column of DM\_SVM\_LINEAR\_COEFF contains Classification target values. For SVM Regression models, class is null. For each Classification target value, a set of coefficients is returned. For Binary Classification, one-class Classification, and Regression models, only a single set of coefficients is returned.
3. The attribute\_value column in DM\_SVM\_ATTRIBUTE\_SET is used for categorical attributes.
4. GET\_MODEL\_DETAILS functions preserve model transparency by automatically reversing the transformations applied during the build process. Thus the attributes returned in the model details are the original attributes (or a close approximation of the original attributes) used to build the model.  
  
The coefficients are related to the transformed, not the original, attributes. When returned directly with the model details, the coefficients may not provide meaningful information. If you want GET\_MODEL\_DETAILS\_SVM to transform the coefficients such that they relate to the original attributes, set the reverse\_coef parameter to 1.
5. When the value is NULL for a partitioned model, an exception is thrown. When the value is not null, it must contain the desired partition name.

## Examples

The following example returns model details for the SVM Classification model SVMC\_SH\_Clas\_sample, which was created by the sample program dmsvcdem.sql. For information about the sample programs, see *Oracle Data Mining User's Guide*.

```
WITH
  mod_dtls AS (
    SELECT *
      FROM TABLE(DBMS_DATA_MINING.GET_MODEL_DETAILS_SVM('SVMC_SH_Clas_sample'))
  ),
  model_details AS (
```

```

SELECT D.class, A.attribute_name, A.attribute_value, A.coefficient
  FROM mod_dtls D,
       TABLE(D.attribute_set) A
 ORDER BY D.class, ABS(A.coefficient) DESC
)
SELECT class, attribute_name aname, attribute_value aval, coefficient coeff
  FROM model_details
 WHERE ROWNUM < 11;

```

| CLASS | ANAME                   | AVAL    | COEFF |
|-------|-------------------------|---------|-------|
| 1     |                         |         | -2.85 |
| 1     | BOOKKEEPING_APPLICATION |         | 1.11  |
| 1     | OCCUPATION              | Other   | -.94  |
| 1     | HOUSEHOLD_SIZE          | 4-5     | .88   |
| 1     | CUST_MARITAL_STATUS     | Married | .82   |
| 1     | YRS_RESIDENCE           |         | .76   |
| 1     | HOUSEHOLD_SIZE          | 6-8     | -.74  |
| 1     | OCCUPATION              | Exec.   | .71   |
| 1     | EDUCATION               | 11th    | -.71  |
| 1     | EDUCATION               | Masters | .63   |

## 48.7.37 GET\_MODEL\_DETAILS\_XML Function

This function returns an XML object that provides the details of a Decision Tree model.

### Syntax

```

DBMS_DATA_MINING.get_model_details_xml(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN XMLType;

```

### Parameters

**Table 48-103 GET\_MODEL\_DETAILS\_XML Function Parameters**

| Parameter      | Description                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| model_name     | Name of the model in the form [schema_name.]model_name. If you do not specify a schema, then your own schema is used. |
| partition_name | Specifies a partition in a partitioned model.                                                                         |

## Return Values

**Table 48-104 GET\_MODEL\_DETAILS\_XML Function Return Value**

| Return Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XMLTYPE      | <p>The XML definition for the Decision Tree model. See "XMLTYPE" for details. The XML definition conforms to the Data Mining Group Predictive Model Markup Language (PMML) version 2.1 specification. The specification is available at <a href="https://dmg.org">https://dmg.org</a>.</p> <p>If a nested attribute is used as a splitter, the attribute will appear in the XML document as field="&lt;column_name&gt;.&lt;subname&gt;", as opposed to the non-nested attributes which appear in the document as field="&lt;column_name&gt;".</p> |

### Note:

The column names are surrounded by single quotes and a period separates the column\_name from the subname.

The rest of the document style remains unchanged.

## Usage Notes

Special characters that cannot be displayed by Oracle XML are converted to '#'.

## Examples

The following statements in SQL\*Plus return the details of the Decision Tree model dt\_sh\_clas\_sample. This model is created by the program dmdtdemo.sql, one of the sample data mining programs provided with Oracle Database Examples.

**Note:** The "&quot;" characters you will see in the XML output are a result of SQL\*Plus behavior. To display the XML in proper format, cut and past it into a file and open the file in a browser.

```
column dt_details format a320
SELECT
  dbms_data_mining.get_model_details_xml('dt_sh_clas_sample')
  AS DT_DETAILS
FROM dual;

## 48.7.38 GET\_MODEL\_TRANSFORMATIONS Function

This function returns the transformation expressions embedded in the specified model. Starting from Oracle Database 12c Release 2, this function is deprecated. See "Static Data Dictionary Views: ALL\_ALL\_TABLES to ALL\_OUTLINES" in *Oracle Database Reference*.

All GET\_\* interfaces are replaced by model views, and Oracle recommends that users reference the model views to retrieve the relevant information. The GET\_MODEL\_TRANSFORMATIONS function is replaced by the following:

- USER/(DBA/ALL)\_MINING\_MODEL\_XFORMS: provides the user-embedded transformations
- DM\$VX prefixed model view: provides text feature extraction information
- D\$VN prefixed mode view: provides normalization and missing value information

- DM\$VB: provides binning information

## Syntax

```
DBMS_DATA_MINING.get_model_transformations(
    model_name IN VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL)
RETURN DM_Transforms PIPELINED;
```

## Parameters

**Table 48-105 GET\_MODEL\_TRANSFORMATIONS Function Parameters**

| Parameter      | Description                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| model_name     | Indicates the name of the model in the form [schema_name.]model_name. If you do not specify a schema, then your own schema is used. |
| partition_name | Specifies a partition in a partitioned model                                                                                        |

## Return Values

**Table 48-106 GET\_MODEL\_TRANSFORMATIONS Function Return Value**

| Return Value       | Description                                                                                                                                                                                                                                                                                                                                                                                             |                |                |                   |                |            |      |                    |      |

## Usage Notes

When Automatic Data Preparation (ADP) is enabled, both automatic and user-defined transformations may be associated with an attribute. In this case, the user-defined transformations are evaluated before the automatic transformations.

When invoked for a partitioned model, the `partition_name` parameter must be specified.

## Examples

In this example, several columns in the `SH.CUSTOMERS` table are used to create a Naive Bayes model. A transformation expression is specified for one of the columns. The model does not use ADP.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_income_level, cust_credit_limit
  FROM sh.customers;

describe mining_data

## 48.7.39 GET\_TRANSFORM\_LIST Procedure

This procedure converts transformation expressions specified as `DM_TRANSFORMS` to a transformation list (`TRANSFORM_LIST`) that can be used in creating a model. `DM_TRANSFORMS` is returned by the `GET_MODEL_TRANSFORMATIONS` function.

You can also use routines in the `DBMS_DATA_MINING_TRANSFORM` package to construct a transformation list.

### See Also:

“About Transformation Lists” in [DBMS\\_DATA\\_MINING\\_TRANSFORM](#)  
["GET\\_MODEL\\_TRANSFORMATIONS Function"](#)  
["CREATE\\_MODEL Procedure"](#)

### Syntax

```
DBMS_DATA_MINING.GET_TRANSFORM_LIST (
    xform_list          OUT NOCOPY TRANSFORM_LIST,
    model_xforms        IN  DM_TRANSFORMS);
```

### Parameters

**Table 48-107 GET\_TRANSFORM\_LIST Procedure Parameters**

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                             |                            |                                |                              |                         |                             |                                 |                             |                             |                              |

| attribute_subname  | VARCHAR2(4000)                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                |                   |                |            |      |                    |      |
| expression         | CLOB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                |                   |                |            |      |                    |      |
| reverse_expression | CLOB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                |                   |                |            |      |                    |      |

### Examples

In this example, a model `mod1` is trained using several columns in the `SH.CUSTOMERS` table. The model uses ADP, which automatically bins one of the columns.

A second model `mod2` is trained on the same data without ADP, but it uses a transformation list that was obtained from `mod1`. As a result, both `mod1` and `mod2` have the same embedded transformation expression.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_income_level, cust_credit_limit
  FROM sh.customers;

## 48.7.40 IMPORT\_MODEL Procedure

This procedure imports one or more data mining models. The procedure is overloaded. You can call it to import mining models from a dump file set, or you can call it to import a single mining model from a PMML document.

### Import from a dump file set

You can import mining models from a dump file set that was created by the [EXPORT\\_MODEL Procedure](#). `IMPORT_MODEL` and `EXPORT_MODEL` use Oracle Data Pump technology to export to and import from a dump file set.

When Oracle Data Pump is used directly to export/import an entire schema or database, the mining models in the schema or database are included. `EXPORT_MODEL` and `IMPORT_MODEL` export/import mining models only.

### Import from PMML

You can import a mining model represented in Predictive Model Markup Language (PMML). The model must be of type `RegressionModel`, either linear regression or binary logistic regression.

PMML is an XML-based standard specified by the Data Mining Group (<https://dmg.org>). Applications that are PMML-compliant can deploy PMML-compliant models that were created by any vendor. Oracle Data Mining supports the core features of PMML 3.1 for regression models.

### See Also:

*Oracle Data Mining User's Guide* for more information about exporting and importing mining models

*Oracle Database Utilities* for information about Oracle Data Pump

<https://dmg.org/dmg-faq.html> for more information about PMML

## Syntax

Imports a mining model from a dump file set:

```
DBMS_DATA_MINING.IMPORT_MODEL (
    filename          IN  VARCHAR2,
    directory         IN  VARCHAR2,
    model_filter      IN  VARCHAR2 DEFAULT NULL,
    operation         IN  VARCHAR2 DEFAULT NULL,
    remote_link       IN  VARCHAR2 DEFAULT NULL,
    jobname           IN  VARCHAR2 DEFAULT NULL,
    schema_remap      IN  VARCHAR2 DEFAULT NULL,
    tablespace_remap  IN  VARCHAR2 DEFAULT NULL);
```

Imports a mining model from a PMML document:

```
DBMS_DATA_MINING.IMPORT_MODEL (
    model_name      IN  VARCHAR2,
    pmmldoc         IN  XMLTYPE
    strict_check    IN  BOOLEAN DEFAULT FALSE);
```

## Parameters

**Table 48-108 IMPORT\_MODEL Procedure Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename     | <p>Name of the dump file set from which the models should be imported. The dump file set must have been created by the <code>EXPORT_MODEL</code> procedure or the <code>expdp</code> export utility of Oracle Data Pump.</p> <p>The dump file set can contain one or more files. (Refer to "<a href="#">EXPORT_MODEL Procedure</a>" for details.) If the dump file set contains multiple files, you can specify '<code>filename%U</code>' instead of listing them. For example, if your dump file set contains 3 files, <code>archive01.dmp</code>, <code>archive02.dmp</code>, and <code>archive03.dmp</code>, you can import them by specifying '<code>archive%U</code>'.</p>      |
| directory    | <p>Name of a pre-defined directory object that specifies where the dump file set is located. Both the exporting and the importing user must have read/write access to the directory object and to the file system directory that it identifies.</p> <p>Note: The target database must have also have read/write access to the file system directory.</p>                                                                                                                                                                                                                                                                                                                             |
| model_filter | <p>Optional parameter that specifies one or more models to import. If you do not specify a value for <code>model_filter</code>, all models in the dump file set are imported. You can also specify <code>NULL</code> (the default) or '<code>ALL</code>' to import all models.</p> <p>The value of <code>model_filter</code> can be one or more model names. The following are valid filters.</p> <pre>'mymodel1' 'name IN ('mymodel2','mymodel3')'</pre> <p>The first causes <code>IMPORT_MODEL</code> to import a single model named <code>mymodel1</code>. The second causes <code>IMPORT_MODEL</code> to import two models, <code>mymodel2</code> and <code>mymodel3</code>.</p> |
| operation    | <p>Optional parameter that specifies whether to import the models or the SQL statements that create the models. By default, the models are imported.</p> <p>You can specify either of the following values for <code>operation</code>:</p> <ul style="list-style-type: none"> <li>'<code>IMPORT</code>' — Import the models (Default)</li> <li>'<code>SQL_FILE</code>' — Write the SQL DDL for creating the models to a text file. The text file is named <code>job_name.sql</code> and is located in the dump set directory.</li> </ul>                                                                                                                                             |
| remote_link  | <p>Optional parameter that specifies the name of a database link to a remote system. The default value is <code>NULL</code>. A database link is a schema object in a local database that enables access to objects in a remote database. When you specify a value for <code>remote_link</code>, you can import models into the local database from the remote database. The import is fileless; no dump file is involved. The <code>IMP_FULL_DATABASE</code> role is required for importing the remote models. The <code>EXP_FULL_DATABASE</code> privilege, the <code>CREATE DATABASE LINK</code> privilege, and other privileges may also be required.</p>                         |
| jobname      | <p>Optional parameter that specifies the name of the import job. By default, the name has the form <code>username_imp_nnnn</code>, where <code>nnnn</code> is a number. For example, a job name in the <code>SCOTT</code> schema might be <code>SCOTT_imp_134</code>.</p> <p>If you specify a job name, it must be unique within the schema. The maximum length of the job name is 30 characters.</p> <p>A log file for the import job, named <code>jobname.log</code>, is created in the same directory as the dump file set.</p>                                                                                                                                                   |

**Table 48-108 (Cont.) IMPORT\_MODEL Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schema_remap     | <p>Optional parameter for importing into a different schema. By default, models are exported and imported within the same schema.</p> <p>If the dump file set belongs to a different schema, you must specify a schema mapping in the form <i>export_user:import_user</i>. For example, you would specify 'SCOTT:MARY' to import a model exported by SCOTT into the MARY schema.</p> <p>Note: In some cases, you may need to have the IMP_FULL_DATABASE privilege or the SYS role to import a model from a different schema.</p>                                                                     |
| tablespace_remap | <p>Optional parameter for importing into a different tablespace. By default, models are exported and imported within the same tablespace.</p> <p>If the dump file set belongs to a different tablespace, you must specify a tablespace mapping in the form <i>export_tablespace:import_tablespace</i>. For example, you would specify 'TBLSPC01:TBLSPC02' to import a model that was exported from tablespace TBLSPC01 into tablespace TBLSPC02.</p> <p>Note: In some cases, you may need to have the IMP_FULL_DATABASE privilege or the SYS role to import a model from a different tablespace.</p> |
| model_name       | Name for the new model that will be created in the database as a result of an import from PMML. The name must be unique within the user's schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| pmmlidoc         | The PMML document representing the model to be imported. The PMML document has an XMLTYPE object type. See "XMLTYPE" for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| strict_check     | <p>Whether or not an error occurs when the PMML document contains sections that are not part of core PMML (for example, Output or Targets). Oracle Data Mining supports only core PMML; any non-core features may affect the scoring representation.</p> <p>If the PMML does not strictly conform to core PMML and <i>strict_check</i> is set to TRUE, then IMPORT_MODEL returns an error. If <i>strict_check</i> is FALSE (the default), then the error is suppressed. The model may be imported and scored.</p>                                                                                    |

## Examples

1. This example shows a model being exported and imported within the schema *dmuser2*. Then the same model is imported into the *dmuser3* schema. The *dmuser3* user has the IMP\_FULL\_DATABASE privilege. The *dmuser2* user has been assigned the USER2 tablespace; *dmuser3* has been assigned the USER3 tablespace.

```
SQL> connect dmuser2
Enter password: dmuser2_password
Connected.
SQL> select model_name from user_mining_models;

MODEL_NAME
-----
NMF_SH_SAMPLE
SVMO_SH_CLAS_SAMPLE
SVMR_SH_REGR_SAMPLE

-- export the model called NMF_SH_SAMPLE to a dump file in same schema
SQL>EXECUTE DBMS_DATA_MINING.EXPORT_MODEL (
          filename =>'NMF_SH_SAMPLE_out',
          directory =>'DATA_PUMP_DIR',
          model_filter => 'name = 'NMF_SH_SAMPLE'' );
```

```
-- import the model back into the same schema
SQL>EXECUTE DBMS_DATA_MINING.IMPORT_MODEL (
    filename => 'NMF_SH_SAMPLE_out01.dmp',
    directory => 'DATA_PUMP_DIR',
    model_filter => 'name = ''NMF_SH_SAMPLE''');

-- connect as different user
-- import same model into that schema
SQL> connect dmuser3
Enter password: dmuser3_password
Connected.
SQL>EXECUTE DBMS_DATA_MINING.IMPORT_MODEL (
    filename => 'NMF_SH_SAMPLE_out01.dmp',
    directory => 'DATA_PUMP_DIR',
    model_filter => 'name = ''NMF_SH_SAMPLE''',
    operation => 'IMPORT',
    remote_link => NULL,
    jobname => 'nmf_imp_job',
    schema_remap => 'dmuser2:dmuser3',
    tablespace_remap => 'USER2:USER3');
```

The following example shows user MARY importing all models from a dump file, model\_exp\_001.dmp, which was created by user SCOTT. User MARY has been assigned a tablespace named USER2; user SCOTT was assigned the tablespace USERS when the models were exported into the dump file model\_exp\_001.dmp. The dump file is located in the file system directory mapped to a directory object called DM\_DUMP. If user MARY does not have IMP\_FULL\_DATABASE privileges, IMPORT\_MODEL will raise an error.

```
-- import all models
DECLARE
    file_name VARCHAR2(40);
BEGIN
    file_name := 'model_exp_001.dmp';
    DBMS_DATA_MINING.IMPORT_MODEL(
        filename=> 'file_name',
        directory=>'DM_DUMP',
        schema_remap=>'SCOTT:MARY',
        tablespace_remap=>'USERS:USER2');
    DBMS_OUTPUT.PUT_LINE(
        'DBMS_DATA_MINING.IMPORT_MODEL of all models from SCOTT done!');
END;
/
```

2. This example shows how the user xuser could import the model dmuser.r1mod from a remote database. The SQL\*Net connection alias for the remote database is R1DB. The user xuser is assigned the SYSAUX tablespace; the user dmuser is assigned the TBS\_1 tablespace.

```
CONNECT / AS SYSDBA;
GRANT CREATE DATABASE LINK TO xuser;
GRANT imp_full_database TO xuser;
CONNECT xuser/xuserpassword
CREATE DATABASE LINK dmuser_link
    CONNECT TO dmuser IDENTIFIED BY dmuserpassword USING 'R1DB';
EXEC dbms_data_mining.import_model (
    NULL,
    'DMUSER_DIR',
    'R1MOD',
    remote_link => 'DMUSER_LINK', schema_remap => 'DMUSER:XUSER',
    tablespace_remap => 'TBS_1:SYSAUX' );
SELECT name FROM dm_user_models;
```

```
NAME
-----
R1MOD
```

3. This example shows how a PMML document called `SamplePMML1.xml` could be imported from a location referenced by directory object `PMMLDIR` into the schema of the current user. The imported model will be called `PMMLMODEL1`.

```
BEGIN
  dbms_data_mining.import_model ('PMMLMODEL1',
    XMLType (bfilename ('PMMLDIR', 'SamplePMML1.xml'),
      nls_charset_id ('AL32UTF8')
    ));
END;
```

## 48.7.41 IMPORT\_SERMODEL Procedure

This procedure imports the serialized format of the model back into a database.

The import routine takes the serialized content in the `BLOB` and the name of the model to be created with the content. This import does not create model views or tables that are needed for querying model details. The import procedure only provides the ability to score the model.

### Syntax

```
DBMS_DATA_MINING.IMPORT_SERMODEL (
  model_data      IN BLOB,
  model_name      IN VARCHAR2,);
```

### Parameters

**Table 48-109** IMPORT\_SERMODEL Procedure Parameters

| Parameter               | Description                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model_data</code> | Provides model data in <code>BLOB</code> format.                                                                                           |
| <code>model_name</code> | Name of the mining model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, then your own schema is used. |

### Examples

The following statement imports the serialized format of the models.

```
declare
  v_blob blob;
BEGIN
  dbms_lob.createtemporary(v_blob, FALSE);
  -- fill in v_blob from somewhere (e.g., bfile, etc.)
  dbms_data_mining.import_sermodel(v_blob, 'MY_MODEL');
  dbms_lob.freetemporary(v_blob);
END;
/
```

## Related Topics

- [EXPORT\\_SERMODEL Procedure](#)  
This procedure exports the model in a serialized format so that they can be moved to another platform for scoring.

## 48.7.42 JSON Schema for R Extensible Algorithm

Follow JSON schema when creating a new JSON object with flexibility.

### Usage Note

Some flexibility when creating a new JSON object are as follows:

- Partial registration is allowed. For example, detail function can be missing.
- Different orders are allowed. For example, detail function can be written before build function or after the build function.

### Example 48-1 JSON Schema

JSON schema 1.1 for R extensible algorithm:

```
{
  "type": "object",
  "properties": {
    "algo_name_display": { "type" : "object",
                          "properties" : {
                            "language" : { "type" :
"string",
"enum" : ["English", "Spanish", "French"],
"default" : "English"},
                            "name" : { "type" : "string"}}
},
    "function_language": { "type": "string" },
    "mining_function": {
      "type" : "array",
      "items" : [
        { "type" : "object",
          "properties" : {
            "mining_function_name" : { "type" : "string"},
            "build_function": {
              "type": "object",
              "properties": {
                "function_body": { "type": "CLOB" }
              }
            }
          }
        }
      ],
    },
  },
}
```

```

        "detail_function": {
            "type" : "array",
            "items" : [
                { "type": "object",
                  "properties": {
                      "function_body": { "type": "CLOB" },
                      "view_columns": { "type" : "array",
                                         "items" : {
                                             "type" : "object",
                                             "properties" : {
                                                 "name" : { "type" : "string"},
                                                 "type" : { "type" : "string",
                                                             "enum" : ["VARCHAR2",
                                                                    "NUMBER",
                                                                    "DATE",
                                                                    "BOOLEAN"]
                                                         }
                                             }
                                         }
                                     }
            ]
        },
        "score_function": {
            "type": "object",
            "properties": {
                "function_body": { "type": "CLOB" }
            }
        },
        "weight_function": {
            "type": "object",
            "properties": {
                "function_body": { "type": "CLOB" },
            }
        }
    ]
},
"algo_setting": {
    "type" : "array",
    "items" : [
        { "type" : "object",
          "properties" : {
              "name" : { "type" : "string"},

```

```

        "name_display": { "type" : "object",
                          "properties" : {

                                   }
                                   },

        "description_display": { "type" : "object",

        "properties" : {
        "language" : { "type" : "string",
                        "enum" : ["English", "Spanish", "French"],

```

```

        "default" : "English"},
        "name" :
    { "type" : "string"}}
    }
}
]
}
}
}

```

### Example 48-2 JSON object example

The following is an JSON object example that must be passed to the registration procedure:

```

{ "algo_name_display" : {"English", "t1"},
  "function_language" : "R",
  "mining_function" : {
    "mining_function_name" : "CLASSIFICATION",
    "build_function" : {"function_body": "function(dat,
formula, family)
{
    set.seed(1234);
    mod <- glm(formula = formula,
data=dat,
    family=
eval(parse(text=family))); mod}"),
    "score_function" : { "function_body": "function(mod, dat) {
    res <- predict(mod, newdata =
dat,
type='response
    ')};
    res2=data.frame(1-res, res);
res2}"}},
  },
  "algo_setting" : [{"name" :
"dbms_data_mining.odms_m
    issing_value_treatment",
    "name_display" : {"English",
"dbms_data_mining.odms_missing_value
_treatment"},
    "type" : "string",
    "optional" : "TRUE",
    "value" :
"dbms_data_mining.odms_missing_value_mean_mode",
    "categorical choices" :
[ "dbms_data_mining.odms_missing_value_mean_mode",
"dbms_data_mining.odms_missing_value_auto",
"dbms_data_mining.odms_missing_value_delete_row"],
    "description" : {"English",
    "how to
treat missing values"}

```

```

    },
    { "name"          : "RALG_PARAMETER_FAMILY",
      "name_display"  : { "English",
        "RALG_PARAMETER_FAMILY" },
      "type"          : "string",
      "optional"      : "TRUE",
      "value"         : "",
      "description"   : { "English", "R family
parameter in build function" }
    },
  ],
}

```

## 48.7.43 REGISTER\_ALGORITHM Procedure

User can register a new algorithm by providing algorithm name, mining function, and all other algorithm metadata to this function.

### Syntax

```

DBMS_DATA_MINING.REGISTER_ALGORITHM (
    algorithm_name      IN VARCHAR2,
    algorithm_metadata  IN CLOB,
    algorithm_description IN VARCHAR2 DEFAULT NULL);

```

### Parameters

**Table 48-110** REGISTER\_ALGORITHM Procedure Parameters

| Parameter             | Description                   |
|-----------------------|-------------------------------|
| algorithm_name        | Name of the algorithm.        |
| algorithm_metadata    | Metadata of the algorithm.    |
| algorithm_description | Description of the algorithm. |

### Usage Notes

The registration procedure performs the following:

- Checks whether algorithm\_metadata has correct JSON syntax.
- Checks whether the input JSON object follows the predefined JSON schema.
- Checks whether current user has RQADMIN privilege.
- Checks duplicate algorithms such that the same algorithm is not registered twice.
- Checks for missing entries. For example, algorithm name, algorithm type, metadata, and build function.

### Register Algorithms After the JSON Object Is Created

SQL users can register new algorithms by following the given procedure:

Create a JSON object following JSON schema and pass it to REGISTER\_ALGORITHM procedure.

```
BEGIN
  DBMS_DATA_MINING.register_algorithm(
    algorithm_name          =>  't1',
    algorithm_metadata      =>
      '{"function_language" : "R",
       "mining_function" :
         { "mining_function_name" : "CLASSIFICATION",
           "build_function" : {"function_body": "function(dat, formula,
family) { set.seed(1234);
                                     mod <- glm(formula = formula,
data=dat,
                                     family=eval(parse(text=family)))};
mod}}",
       "score_function" : {"function_body": "function(mod, dat) {
                                     res <- predict(mod, newdata =
dat, type=''response'');
                                     res2=data.frame(1-res, res);
res2}}"}',
    algorithm_description   => 't1');
END;
/
```

## 48.7.44 RANK\_APPLY Procedure

This procedure ranks the results of an APPLY operation based on a top-N specification for predictive and descriptive model results.

For classification models, you can provide a cost matrix as input, and obtain the ranked results with costs applied to the predictions.

### Syntax

```
DBMS_DATA_MINING.RANK_APPLY (
  apply_result_table_name      IN VARCHAR2,
  case_id_column_name         IN VARCHAR2,
  score_column_name           IN VARCHAR2,
  score_criterion_column_name IN VARCHAR2,
  ranked_apply_table_name     IN VARCHAR2,
  top_N                       IN NUMBER (38) DEFAULT 1,
  cost_matrix_table_name      IN VARCHAR2      DEFAULT NULL,
  apply_result_schema_name    IN VARCHAR2      DEFAULT NULL,
  cost_matrix_schema_name     IN VARCHAR2      DEFAULT NULL);
```

### Parameters

**Table 48-111 RANK\_APPLY Procedure Parameters**

| Parameter               | Description                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| apply_result_table_name | Name of the table or view containing the results of an APPLY operation on the test data set (see Usage Notes) |

**Table 48-111 (Cont.) RANK\_APPLY Procedure Parameters**

| Parameter                      | Description                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------|
| case_id_column_name            | Name of the case identifier column. This must be the same as the one used for generating APPLY results. |
| score_column_name              | Name of the prediction column in the apply results table                                                |
| score_criterion_column_name    | Name of the probability column in the apply results table                                               |
| ranked_apply_result_table_name | Name of the table containing the ranked apply results                                                   |
| top_N                          | Top N predictions to be considered from the APPLY results for precision recall computation              |
| cost_matrix_table_name         | Name of the cost matrix table                                                                           |
| apply_result_schema_name       | Name of the schema hosting the APPLY results table                                                      |
| cost_matrix_schema_name        | Name of the schema hosting the cost matrix table                                                        |

### Usage Notes

You can use `RANK_APPLY` to generate ranked apply results, based on a top-N filter and also with application of cost for predictions, if the model was built with costs.

The behavior of `RANK_APPLY` is similar to that of `APPLY` with respect to other DDL-like operations such as `CREATE_MODEL`, `DROP_MODEL`, and `RENAME_MODEL`. The procedure does not depend on the model; the only input of relevance is the apply results generated in a fixed schema table from `APPLY`.

The main intended use of `RANK_APPLY` is for the generation of the final `APPLY` results against the scoring data in a production setting. You can apply the model against test data using `APPLY`, compute various test metrics against various cost matrix tables, and use the candidate cost matrix for `RANK_APPLY`.

The schema for the apply results from each of the supported algorithms is listed in subsequent sections. The `case_id` column will be the same case identifier column as that of the apply results.

### Classification Models — NB and SVM

For numerical targets, the ranked results table will have the definition as shown:

```
(case_id      VARCHAR2/NUMBER,
 prediction    NUMBER,
 probability   NUMBER,
 cost         NUMBER,
 rank         INTEGER)
```

For categorical targets, the ranked results table will have the following definition:

```
(case_id      VARCHAR2/NUMBER,
 prediction    VARCHAR2,
 probability   NUMBER,
 cost         NUMBER,
 rank         INTEGER)
```

### Clustering Using *k*-Means or O-Cluster

Clustering is an unsupervised mining function, and hence there are no targets. The results of an `APPLY` operation contains simply the cluster identifier corresponding to a case, and the associated probability. Cost matrix is not considered here. The ranked results table will have the definition as shown, and contains the cluster ids ranked by `top-N`.

```
(case_id      VARCHAR2/NUMBER,
cluster_id    NUMBER,
probability    NUMBER,
rank          INTEGER)
```

### Feature Extraction using NMF

Feature extraction is also an unsupervised mining function, and hence there are no targets. The results of an `APPLY` operation contains simply the feature identifier corresponding to a case, and the associated match quality. Cost matrix is not considered here. The ranked results table will have the definition as shown, and contains the feature ids ranked by `top-N`.

```
(case_id      VARCHAR2/NUMBER,
feature_id    NUMBER,
match_quality  NUMBER,
rank          INTEGER)
```

### Examples

```
BEGIN
/* build a model with name census_model.
 * (See example under CREATE_MODEL)
 */

/* if training data was pre-processed in any manner,
 * perform the same pre-processing steps on apply
 * data also.
 * (See examples in the section on DBMS_DATA_MINING_TRANSFORM)
 */

/* apply the model to data to be scored */
DBMS_DATA_MINING.RANK_APPLY(
  apply_result_table_name => 'census_apply_result',
  case_id_column_name     => 'person_id',
  score_column_name       => 'prediction',
  score_criterion_column_name => 'probability'
  ranked_apply_result_tab_name => 'census_ranked_apply_result',
  top_N                   => 3,
  cost_matrix_table_name  => 'census_cost_matrix');
END;
/

-- View Ranked Apply Results
SELECT *
  FROM census_ranked_apply_result;
```

## 48.7.45 REMOVE\_COST\_MATRIX Procedure

The `REMOVE_COST_MATRIX` procedure removes the default scoring matrix from a classification model.

### See Also:

- ["ADD\\_COST\\_MATRIX Procedure"](#)
- ["REMOVE\\_COST\\_MATRIX Procedure"](#)

### Syntax

```
DBMS_DATA_MINING.REMOVE_COST_MATRIX (
    model_name    IN  VARCHAR2);
```

### Parameters

**Table 48-112 Remove\_Cost\_Matrix Procedure Parameters**

| Parameter               | Description                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>model_name</code> | Name of the model in the form <code>[schema_name.]model_name</code> . If you do not specify a schema, your own schema is used. |

### Usage Notes

If the model is not in your schema, then `REMOVE_COST_MATRIX` requires the `ALTER ANY MINING MODEL` system privilege or the `ALTER` object privilege for the mining model.

### Example

The Naive Bayes model `NB_SH_CLAS_SAMPLE` has an associated cost matrix that can be used for scoring the model.

```
SQL>SELECT *
      FROM TABLE(dbms_data_mining.get_model_cost_matrix('nb_sh_clas_sample'))
      ORDER BY predicted, actual;
```

| ACTUAL | PREDICTED | COST |
|--------|-----------|------|
| 0      | 0         | 0    |
| 1      | 0         | .75  |
| 0      | 1         | .25  |
| 1      | 1         | 0    |

You can remove the cost matrix with `REMOVE_COST_MATRIX`.

```
SQL>EXECUTE dbms_data_mining.remove_cost_matrix('nb_sh_clas_sample');
```

```
SQL>SELECT *
      FROM TABLE(dbms_data_mining.get_model_cost_matrix('nb_sh_clas_sample'))
      ORDER BY predicted, actual;
```

no rows selected

## 48.7.46 RENAME\_MODEL Procedure

This procedure changes the name of the mining model indicated by *model\_name* to the name that you specify as *new\_model\_name*.

If a model with *new\_model\_name* already exists, then the procedure optionally renames *new\_model\_name* to *versioned\_model\_name* before renaming *model\_name* to *new\_model\_name*.

The model name is in the form [*schema\_name*.]*model\_name*. If you do not specify a schema, your own schema is used. For mining model naming restrictions, see the Usage Notes for "[CREATE\\_MODEL Procedure](#)".

### Syntax

```
DBMS_DATA_MINING.RENAME_MODEL (
    model_name          IN VARCHAR2,
    new_model_name      IN VARCHAR2,
    versioned_model_name IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 48-113 RENAME\_MODEL Procedure Parameters**

| Parameter                   | Description                                                        |
|-----------------------------|--------------------------------------------------------------------|
| <i>model_name</i>           | Model to be renamed.                                               |
| <i>new_model_name</i>       | New name for the model <i>model_name</i> .                         |
| <i>versioned_model_name</i> | New name for the model <i>new_model_name</i> if it already exists. |

### Usage Notes

If you attempt to rename a model while it is being applied, then the model will be renamed but the apply operation will return indeterminate results.

### Examples

1. This example changes the name of model `census_model` to `census_model_2012`.

```
BEGIN
    DBMS_DATA_MINING.RENAME_MODEL(
        model_name      => 'census_model',
        new_model_name  => 'census_model_2012');
END;
/
```

2. In this example, there are two classification models in the user's schema: `clas_mod`, the working model, and `clas_mod_tst`, a test model. The `RENAME_MODEL` procedure preserves `clas_mod` as `clas_mod_old` and makes the test model the new working model.

```
SELECT model_name FROM user_mining_models;
MODEL_NAME
-----
CLAS_MOD
CLAS_MOD_TST

BEGIN
    DBMS_DATA_MINING.RENAME_MODEL (
```

```
        model_name          => 'clas_mod_tst',  
        new_model_name      => 'clas_mod',  
        versioned_model_name => 'clas_mod_old');  
END;  
/
```

```
SELECT model_name FROM user_mining_models;  
MODEL_NAME
```

```
-----  
CLAS_MOD  
CLAS_MOD_OLD
```

# DBMS\_DATA\_MINING\_TRANSFORM

DBMS\_DATA\_MINING\_TRANSFORM implements a set of transformations that are commonly used in data mining.

This chapter contains the following topics:

- [Overview](#)
- [Operational Notes](#)
- [Security Model](#)
- [Datatypes](#)
- [Constants](#)
- [Summary of DBMS\\_DATA\\_MINING\\_TRANSFORM Subprograms](#)

## See Also:

- [DBMS\\_DATA\\_MINING](#)
- *Oracle Data Mining User's Guide*

## 49.1 DBMS\_DATA\_MINING\_TRANSFORM Overview

A transformation is a SQL expression that modifies the data in one or more columns.

Data must typically undergo certain transformations before it can be used to build a mining model. Many data mining algorithms have specific transformation requirements.

Data that will be scored must be transformed in the same way as the data that was used to create (train) the model.

### External or Embedded Transformations

DBMS\_DATA\_MINING\_TRANSFORM offers two approaches to implementing transformations. For a given model, you can either:

- Create a list of transformation expressions and pass it to the [CREATE\\_MODEL Procedure](#)  
*or*
- Create a view that implements the transformations and pass the name of the view to the [CREATE\\_MODEL Procedure](#)

If you create a transformation list and pass it to CREATE\_MODEL, the transformation expressions are embedded in the model and automatically implemented whenever the model is applied.

If you create a view, the transformation expressions are external to the model. You will need to re-create the transformations whenever you apply the model.

**Note:**

Embedded transformations significantly enhance the model's usability while simplifying the process of model management.

**Automatic Transformations**

Oracle Data Mining supports an Automatic Data Preparation (ADP) mode. When ADP is enabled, most algorithm-specific transformations are *automatically* embedded. Any additional transformations must be explicitly provided in an embedded transformation list or in a view.

If ADP is enabled and you create a model with a transformation list, both sets of transformations are embedded. The model will execute the user-specified transformations from the transformation list before executing the automatic transformations specified by ADP.

Within a transformation list, you can selectively disable ADP for individual attributes.

**See Also:**

["Automatic Data Preparation" in DBMS\\_DATA\\_MINING](#)

*Oracle Data Mining User's Guide* for a more information about ADP

["DBMS\\_DATA\\_MINING\\_TRANSFORM-About Transformation Lists"](#)

**Transformations in DBMS\_DATA\_MINING\_TRANSFORM**

The transformations supported by `DBMS_DATA_MINING_TRANSFORM` are summarized in this section.

**Binning**

Binning refers to the mapping of continuous or discrete values to discrete values of reduced cardinality.

- **Supervised Binning (Categorical and Numerical)**  
Binning is based on intrinsic relationships in the data as determined by a decision tree model.  
See ["INSERT\\_BIN\\_SUPER Procedure"](#).
- **Top-N Frequency Categorical Binning**  
Binning is based on the number of cases in each category.  
See ["INSERT\\_BIN\\_CAT\\_FREQ Procedure"](#)
- **Equi-Width Numerical Binning**  
Binning is based on equal-range partitions.  
See ["INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure"](#).
- **Quantile Numerical Binning**  
Binning is based on quantiles computed using the SQL `NTILE` function.  
See ["INSERT\\_BIN\\_NUM\\_QTILE Procedure"](#).

## Linear Normalization

Normalization is the process of scaling continuous values down to a specific range, often between zero and one. Normalization transforms each numerical value by subtracting a number (the **shift**) and dividing the result by another number (the **scale**).

$$x_{\text{new}} = (x_{\text{old}} - \text{shift}) / \text{scale}$$

- **Min-Max Normalization**

Normalization is based on the minimum and maximum with the following shift and scale:

```
shift = min
scale = max-min
```

See "[INSERT\\_NORM\\_LIN\\_MINMAX Procedure](#)".

- **Scale Normalization**

Normalization is based on the minimum and maximum with the following shift and scale:

```
shift = 0
scale = max{abs(max), abs(min)}
```

See "[INSERT\\_NORM\\_LIN\\_SCALE Procedure](#)".

- **Z-Score Normalization**

Normalization is based on the mean and standard deviation with the following shift and scale:

```
shift = mean
scale = standard_deviation
```

See "[INSERT\\_NORM\\_LIN\\_ZSCORE Procedure](#)".

## Outlier Treatment

An outlier is a numerical value that is located far from the rest of the data. Outliers can artificially skew the results of data mining.

- **Winsorizing**

Outliers are replaced with the nearest value that is not an outlier.

See "[INSERT\\_CLIP\\_WINSOR\\_TAIL Procedure](#)".

- **Trimming**

Outliers are set to NULL.

See "[INSERT\\_CLIP\\_TRIM\\_TAIL Procedure](#)".

## Missing Value Treatment

Missing data may indicate sparsity or it may indicate that some values are missing at random. DBMS\_DATA\_MINING\_TRANSFORM supports the following transformations for minimizing the effects of missing values:

- Missing numerical values are replaced with the mean.  
See "[INSERT\\_MISS\\_NUM\\_MEAN Procedure](#)".
- Missing categorical values are replaced with the mode.  
See "[INSERT\\_MISS\\_CAT\\_MODE Procedure](#)".

**Note:**

Oracle Data Mining also has default mechanisms for handling missing data. See *Oracle Data Mining User's Guide* for details.

## 49.2 DBMS\_DATA\_MINING\_TRANSFORM Operational Notes

The `DBMS_DATA_MINING_TRANSFORM` package offers a flexible framework for specifying data transformations. If you choose to embed transformations in the model (the preferred method), you create a **transformation list** object and pass it to the `CREATE_MODEL` Procedure. If you choose to transform the data without embedding, you create a view.

When specified in a transformation list, the transformation expressions are executed by the model. When specified in a view, the transformation expressions are executed by the view.

### Transformation Definitions

Transformation definitions are used to generate the SQL expressions that transform the data. For example, the transformation definitions for normalizing a numeric column are the shift and scale values for that data.

With the `DBMS_DATA_MINING_TRANSFORM` package, you can call procedures to compute the transformation definitions, or you can compute them yourself, or you can do both.

### Transformation Definition Tables

`DBMS_DATA_MINING_TRANSFORM` provides **INSERT** procedures that compute transformation definitions and insert them in transformation definition tables. You can modify the values in the transformation definition tables or populate them yourself.

**XFORM** routines use populated definition tables to transform data in external views. **STACK** routines use populated definition tables to build transformation lists.

To specify transformations based on definition tables, follow these steps:

1. Use **CREATE** routines to create transformation definition tables.

The tables have columns to hold the transformation definitions for a given type of transformation. For example, the [CREATE\\_BIN\\_NUM Procedure](#) creates a definition table that has a column for storing data values and another column for storing the associated bin identifiers.

2. Use **INSERT** routines to compute and insert transformation definitions in the tables.

Each **INSERT** routine uses a specific technique for computing the transformation definitions. For example, the [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) computes bin boundaries by identifying the minimum and maximum values then setting the bin boundaries at equal intervals.

3. Use **STACK** or **XFORM** routines to generate transformation expressions based on the information in the definition tables:

- Use **STACK** routines to add the transformation expressions to a transformation list. Pass the transformation list to the [CREATE\\_MODEL Procedure](#). The transformation expressions will be assembled into one long SQL query and embedded in the model.

- Use **XFORM** routines to execute the transformation expressions within a view. The transformations will be external to the model and will need to be re-created whenever the model is applied to new data.

### Transformations Without Definition Tables

**STACK** routines are not the only method for adding transformation expressions to a transformation list. You can also build a transformation list without using definition tables.

To specify transformations without using definition tables, follow these steps:

1. Write a SQL expression for transforming an attribute.
2. Write a SQL expression for reversing the transformation. (See "Reverse Transformations and Model Transparency" in "[DBMS\\_DATA\\_MINING\\_TRANSFORM-About Transformation Lists](#)".)
3. Determine whether or not to disable ADP for the attribute. By default ADP is enabled for the attribute if it is specified for the model. (See "Disabling Automatic Data Preparation" in "[DBMS\\_DATA\\_MINING\\_TRANSFORM - About Transformation Lists](#)".)
4. Specify the SQL expressions and ADP instructions in a call to the [SET\\_TRANSFORM Procedure](#), which adds the information to a transformation list.
5. Repeat steps 1 through 4 for each attribute that you wish to transform.
6. Pass the transformation list to the [CREATE\\_MODEL Procedure](#). The transformation expressions will be assembled into one long SQL query and embedded in the model.

#### Note:

SQL expressions that you specify with **SET\_TRANSFORM** must fit within a **VARCHAR2**. To specify a longer expression, you can use the [SET\\_EXPRESSION Procedure](#). With **SET\_EXPRESSION**, you can build an expression by appending rows to a **VARCHAR2** array.

### About Stacking

Transformation lists are built by stacking transformation records. Transformation lists are evaluated from bottom to top. Each transformation expression depends on the result of the transformation expression below it in the stack.

### Related Topics

- [CREATE\\_MODEL Procedure](#)  
This procedure creates a mining model with a given mining function.
- [DBMS\\_DATA\\_MINING\\_TRANSFORM — About Transformation Lists](#)  
The elements of a transformation list are **transformation records**. Each transformation record provides all the information needed by the model for managing the transformation of a single attribute.
- [DBMS\\_DATA\\_MINING\\_TRANSFORM — About Stacking and Stack Procedures](#)  
Transformation lists are built by stacking transformation records. Transformation lists are evaluated from bottom to top. Each transformation expression depends on the result of the transformation expression below it in the stack.
- [DBMS\\_DATA\\_MINING\\_TRANSFORM — Nested Data Transformations](#)  
The **CREATE** routines create transformation definition tables that include two columns, **col** and **att**, for identifying attributes. The column **col** holds the name of a column in the data

table. If the data column is not nested, then `att` is null, and the name of the attribute is `col`. If the data column is nested, then `att` holds the name of the nested attribute, and the name of the attribute is `col.att`.

## 49.2.1 DBMS\_DATA\_MINING\_TRANSFORM — About Transformation Lists

The elements of a transformation list are **transformation records**. Each transformation record provides all the information needed by the model for managing the transformation of a single attribute.

Each transformation record includes the following fields:

- `attribute_name` — Name of the column of data to be transformed
- `attribute_subname` — Name of the nested attribute if `attribute_name` is a nested column, otherwise NULL
- `expression` — SQL expression for transforming the attribute
- `reverse_expression` — SQL expression for reversing the transformation
- `attribute_spec` — Identifies special treatment for the attribute during the model build. See [Table 49-33](#) for details.

### See Also:

- [Table 49-1](#) for details about the `TRANSFORM_LIST` and `TRANSFORM_REC` object types
- [SET\\_TRANSFORM Procedure](#)
- [CREATE\\_MODEL Procedure](#)

### Reverse Transformations and Model Transparency

An algorithm manipulates transformed attributes to train and score a model. The transformed attributes, however, may not be meaningful to an end user. For example, if attribute `x` has been transformed into bins 1 — 4, the bin names 1, 2, 3, and 4 are manipulated by the algorithm, but a user is probably not interested in the model details about bins 1 — 4 or in predicting the numbers 1 — 4.

To return original attribute values in model details and predictions, you can provide a reverse expression in the transformation record for the attribute. For example, if you specify the transformation expression `'log(10, y)'` for attribute `y`, you could specify the reverse transformation expression `'power(10, y)'`.

Reverse transformations enable **model transparency**. They make internal processing transparent to the user.

**Note:**

STACK procedures automatically reverse normalization transformations, but they do not provide a mechanism for reversing binning, clipping, or missing value transformations.

You can use the `DBMS_DATA_MINING.ALTER_REVERSE_EXPRESSION` procedure to specify or update reverse transformations expressions for an existing model.

**See Also:**

[Table 49-1](#)

["ALTER\\_REVERSE\\_EXPRESSION Procedure"](#)

["Summary of DBMS\\_DATA\\_MINING Subprograms"](#) for links to the model details functions

**Disabling Automatic Data Preparation**

ADP is controlled by a model-specific setting (`PREP_AUTO`). The `PREP_AUTO` setting affects all model attributes unless you disable it for individual attributes.

If ADP is enabled and you set `attribute_spec` to `NOPREP`, only the transformations that you specify for that attribute will be evaluated. If ADP is enabled and you do *not* set `attribute_spec` to `NOPREP`, the automatic transformations will be evaluated *after* the transformations that you specify for the attribute.

If ADP is not enabled for the model, the `attribute_spec` field of the transformation record is ignored.

**See Also:**

["Automatic Data Preparation"](#) for information about the `PREP_AUTO` setting

**Adding Transformation Records to a Transformation List**

A transformation list is a stack of transformation records. When a new transformation record is added, it is appended to the top of the stack. (See ["About Stacking"](#) for details.)

When you use `SET_TRANSFORM` to add a transformation record to a transformation list, you can specify values for all the fields in the transformation record.

When you use `STACK` procedures to add transformation records to a transformation list, only the transformation expression field is populated. For normalization transformations, the reverse transformation expression field is also populated.

You can use both `STACK` procedures and `SET_TRANSFORM` to build one transformation list. Each `STACK` procedure call adds transformation records for all the attributes in a specified

transformation definition table. Each `SET_TRANSFORM` call adds a transformation record for a single attribute.

## 49.2.2 DBMS\_DATA\_MINING\_TRANSFORM — About Stacking and Stack Procedures

Transformation lists are built by stacking transformation records. Transformation lists are evaluated from bottom to top. Each transformation expression depends on the result of the transformation expression below it in the stack.

### Stack Procedures

`STACK` procedures create transformation records from the information in transformation definition tables. For example `STACK_BIN_NUM` builds a transformation record for each attribute specified in a definition table for numeric binning. `STACK` procedures stack the transformation records as follows:

- If an attribute is specified in the definition table but not in the transformation list, the `STACK` procedure creates a transformation record, computes the reverse transformation (if possible), inserts the transformation and reverse transformation in the transformation record, and appends the transformation record to the top of the transformation list.
- If an attribute is specified in the transformation list but not in the definition table, the `STACK` procedure takes no action.
- If an attribute is specified in the definition table *and* in the transformation list, the `STACK` procedure stacks the transformation expression from the definition table on top of the transformation expression in the transformation record and updates the reverse transformation. See [Table 49-1](#) and [Example 49-4](#).

### Example 49-1 Stacking a Clipping Transformation

This example shows how [STACK\\_CLIP Procedure](#) would add transformation records to a transformation list. Note that the clipping transformations are not reversed in `COL1` and `COL2` after stacking (as described in "Reverse Transformations and Model Transparency" in "DBMS\_DATA\_MINING\_TRANSFORM-About Transformation Lists").

Refer to:

- [CREATE\\_CLIP Procedure](#) — Creates the definition table
- [INSERT\\_CLIP\\_TRIM\\_TAIL Procedure](#) — Inserts definitions in the table
- [INSERT\\_CLIP\\_WINSOR\\_TAIL Procedure](#) — Inserts definitions in the table
- [Table 49-1](#) — Describes the structure of the transformation list (`TRANSFORM_LIST` object)

Assume a clipping definition table populated as follows.

| col  | att  | lcut | lval | rcut | rval |
|------|------|------|------|------|------|
| COL1 | null | -1.5 | -1.5 | 4.5  | 4.5  |
| COL2 | null | 0    | 0    | 1    | 1    |

Assume the following transformation list before stacking.

```
-----
transformation record #1:
-----
```

```

attribute_name      = COL1
attribute_subname    = null
expression          = log(10, COL1)
reverse_expression   = power(10, COL1)

```

```
-----
transformation record #2:
-----
```

```

attribute_name      = COL3
attribute_subname    = null
expression          = ln(COL3)
reverse_expression   = exp(COL3)

```

**After stacking, the transformation list is as follows.**

```
-----
transformation record #1:
-----
```

```

attribute_name      = COL1
attribute_subname    = null
expression          = CASE WHEN log(10, COL1) < -1.5 THEN -1.5
                        WHEN log(10, COL1) > 4.5 THEN 4.5
                        ELSE log(10, COL1)
                        END;
reverse_expression   = power(10, COL1)

```

```
-----
transformation record #2:
-----
```

```

attribute_name      = COL3
attribute_subname    = null
expression          = ln(COL3)
reverse_expression   = exp(COL3)

```

```
-----
transformation record #3:
-----
```

```

attribute_name      = COL2
attribute_subname    = null
expression          = CASE WHEN COL2 < 0 THEN 0
                        WHEN COL2 > 1 THEN 1
                        ELSE COL2
                        END;
reverse_expression   = null

```

## 49.2.3 DBMS\_DATA\_MINING\_TRANSFORM — Nested Data Transformations

The **CREATE** routines create transformation definition tables that include two columns, `col` and `att`, for identifying attributes. The column `col` holds the name of a column in the data table. If the data column is not nested, then `att` is null, and the name of the attribute is `col`. If the data column is nested, then `att` holds the name of the nested attribute, and the name of the attribute is `col.att`.

The **INSERT** and **XFORM** routines ignore the `att` column in the definition tables. Neither the **INSERT** nor the **XFORM** routines support nested data.

Only the **STACK** procedures and **SET\_TRANSFORM** support nested data. Nested data transformations are always embedded in the model.

feature 322331-1 Native doubles in DMFs

Nested columns in Oracle Data Mining can have the following types:

```
DM_NESTED_NUMERICALS
DM_NESTED_CATEGORICALS

*Oracle Data Mining User's Guide* for details about nested attributes in Oracle Data Mining

## Specifying Nested Attributes in a Transformation Record

A transformation record (TRANSFORM\_REC) includes two fields, `attribute_name` and `attribute_subname`, for identifying the attribute. The field `attribute_name` holds the name of a column in the data table. If the data column is not nested, then `attribute_subname` is null, and the name of the attribute is `attribute_name`. If the data column is nested, then `attribute_subname` holds the name of the nested attribute, and the name of the attribute is `attribute_name.attribute_subname`.

## Transforming Individual Nested Attributes

You can specify different transformations for different attributes in a nested column, and you can specify a default transformation for all the remaining attributes in the column. To specify a default nested transformation, specify null in the `attribute_name` field and the name of the nested column in the `attribute_subname` field as shown in [Example 49-2](#). Note that the keyword `VALUE` is used to represent the value of a nested attribute in a transformation expression.

### Example 49-2 Transforming a Nested Column

The following statement transforms two of the nested attributes in `COL_N1`. Attribute `ATTR1` is transformed with normalization; Attribute `ATTR2` is set to null, which causes attribute removal transformation (`ATTR2` is not used in training the model). All the remaining attributes in `COL_N1` are divided by 10.

```
DECLARE
  stk dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
  dbms_data_mining_transform.SET_TRANSFORM(
    stk, 'COL_N1', 'ATTR1', '(VALUE - (-1.5))/20', 'VALUE *20 + (-1.5)');
  dbms_data_mining_transform.SET_TRANSFORM(
    stk, 'COL_N1', 'ATTR2', NULL, NULL);
  dbms_data_mining_transform.SET_TRANSFORM(
    stk, NULL, 'COL_N1', 'VALUE/10', 'VALUE*10');
END;
/
```

The following SQL is generated from this statement.

```
CAST(MULTISET(SELECT DM_NESTED_NUMERICAL(
  "ATTRIBUTE_NAME",
  DECODE("ATTRIBUTE_NAME",
    'ATTR1', ("VALUE" - (-1.5))/20,
    "VALUE"/10))
FROM TABLE("COL_N1")
```

```

        WHERE "ATTRIBUTE_NAME" IS NOT IN ('ATTR2'))
    AS DM_NESTED_NUMERICALS)

```

If transformations are not specified for COL\_N1.ATTR1 and COL\_N1.ATTR2, then the default transformation is used for all the attributes in COL\_N1, and the resulting SQL does not include a DECODE.

```

    CAST(MULTISET(SELECT DM_NESTED_NUMERICAL(
                        "ATTRIBUTE_NAME",
                        "VALUE"/10)
                FROM TABLE("COL_N1"))
    AS DM_NESTED_NUMERICALS)

```

Since DECODE is limited to 256 arguments, multiple DECODE functions are nested to support an arbitrary number of individual nested attribute specifications.

### Adding a Nested Column

You can specify a transformation that adds a nested column to the data, as shown in [Example 49-3](#).

#### Example 49-3 Adding a Nested Column to a Transformation List

```

DECLARE
    v_xlst dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.SET_TRANSFORM(v_xlst,
        'YOB_CREDLIM', NULL,
        'dm_nested_numericals(
            dm_nested_numerical(
                'CUST_YEAR_OF_BIRTH', cust_year_of_birth),
            dm_nested_numerical(
                'CUST_CREDIT_LIMIT', cust_credit_limit))',
        NULL);
    dbms_data_mining_transform.SET_TRANSFORM(
        v_xlst, 'CUST_YEAR_OF_BIRTH', NULL, NULL, NULL);
    dbms_data_mining_transform.SET_TRANSFORM(
        v_xlst, 'CUST_CREDIT_LIMIT', NULL, NULL, NULL);
    dbms_data_mining_transform.XFORM_STACK(
        v_xlst, 'mining_data', 'mining_data_v');
END;
/

set long 2000
SELECT text FROM user_views WHERE view_name IN 'MINING_DATA_V';

TEXT
-----
SELECT "CUST_ID","CUST_POSTAL_CODE",dm_nested_numericals(
    dm_nested_numerical(
        'CUST_YEAR_OF_BIRTH', cust_year_of_birth),
    dm_nested_numerical(
        'CUST_CREDIT_LIMIT', cust_credit_limit)) "YOB_CREDLIM" FROM mining_data

SELECT * FROM mining_data_v WHERE cust_id = 104500;

CUST_ID CUST_POSTAL_CODE YOB_CREDLIM(ATTRIBUTE_NAME, VALUE)
-----
104500 68524           DM_NESTED_NUMERICALS(DM_NESTED_NUMERICAL(
                        'CUST_YEAR_OF_BIRTH', 1962),
                        DM_NESTED_NUMERICAL('CUST_CREDIT_LIMIT', 15000))

```

## Stacking Nested Transformations

Example 49-4 shows how the [STACK\\_NORM\\_LIN Procedure](#) would add transformation records for nested column COL\_N to a transformation list.

Refer to:

- [CREATE\\_NORM\\_LIN Procedure](#) — Creates the definition table
- [INSERT\\_NORM\\_LIN\\_MINMAX Procedure](#) — Inserts definitions in the table
- [INSERT\\_NORM\\_LIN\\_SCALE Procedure](#) — Inserts definitions in the table
- [INSERT\\_NORM\\_LIN\\_ZSCORE Procedure](#) — Inserts definitions in the table
- [Table 49-1](#) — Describes the structure of the transformation list

### Example 49-4 Stacking a Nested Normalization Transformation

Assume a linear normalization definition table populated as follows.

| col   | att   | shift | scale |
|-------|-------|-------|-------|
| COL_N | ATT2  | 0     | 20    |
| null  | COL_N | 0     | 10    |

Assume the following transformation list before stacking.

```

-----
transformation record #1:
-----
    attribute_name      = COL_N
    attribute_subname    = ATT1
    expression          = log(10, VALUE)
    reverse_expression   = power(10, VALUE)
-----
transformation record #2:
-----
    attribute_name      = null
    attribute_subname    = COL_N
    expression          = ln(VALUE)
    reverse_expression   = exp(VALUE)

```

After stacking, the transformation list is as follows.

```

-----
transformation record #1:
-----
    attribute_name      = COL_N
    attribute_subname    = ATT1
    expression          = (log(10, VALUE) - 0)/10
    reverse_expression   = power(10, VALUE*10 + 0)
-----
transformation record #2:
-----
    attribute_name      = NULL
    attribute_subname    = COL_N
    expression          = (ln(VALUE)- 0)/10
    reverse_expression   = exp(VALUE *10 + 0)
-----
transformation record #3:
-----

```

```

attribute_name      = COL_N
attribute_subname   = ATT2
expression          = (ln(VALUE) - 0)/20
reverse_expression  = exp(VALUE * 20 + 0)

```

## 49.3 DBMS\_DATA\_MINING\_TRANSFORM Security Model

The `DBMS_DATA_MINING_TRANSFORM` package is owned by user `SYS` and is installed as part of database installation. Execution privilege on the package is granted to public. The routines in the package are run with invokers' rights (run with the privileges of the current user).

The `DBMS_DATA_MINING_TRANSFORM.INSERT_*` procedures have a `data_table_name` parameter that enables the user to provide the input data for transformation purposes. The value of `data_table_name` can be the name of a physical table or a view. The `data_table_name` parameter can also accept an inline query.

### Note:

Because an inline query can be used to specify the data for transformation, Oracle strongly recommends that the calling routine perform any necessary SQL injection checks on the input string.

### See Also:

"[Operational Notes](#)" for a description of the `DBMS_DATA_MINING_TRANSFORM.INSERT_*` procedures

## 49.4 DBMS\_DATA\_MINING\_TRANSFORM Datatypes

`DBMS_DATA_MINING_TRANSFORM` defines the datatypes described in the following table.

**Table 49-1 Datatypes in DBMS\_DATA\_MINING\_TRANSFORM**

| List Type                | List Elements                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>COLUMN_LIST</code> | <code>VARRAY(1000) OF varchar2(32)</code> | <p><code>COLUMN_LIST</code> stores quoted and non-quoted identifiers for column names.</p> <p><code>COLUMN_LIST</code> is the datatype of the <code>exclude_list</code> parameter in the <code>INSERT</code> procedures. See "<a href="#">INSERT_AUTOBIN_NUM_EQWIDTH Procedure</a>" for an example.</p> <p>See <i>Oracle Database PL/SQL Language Reference</i> for information about populating <code>VARRAY</code> structures.</p> |

Table 49-1 (Cont.) Datatypes in DBMS\_DATA\_MINING\_TRANSFORM

| List Type             | List Elements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DESCRIBE_LIST</b>  | <pre> DBMS_SQL.DESC_TAB2  TYPE desc_tab2 IS TABLE OF desc_rec2 INDEX BY BINARY_INTEGER  TYPE desc_rec2 IS RECORD ( col_type          BINARY_INTEGER := 0, col_max_len       BINARY_INTEGER := 0, col_name          VARCHAR2(32767) := '', col_name_len      BINARY_INTEGER := 0, col_schema_name   VARCHAR2(32)    := '', col_schema_name_len BINARY_INTEGER := 0, col_precision     BINARY_INTEGER := 0, col_scale         BINARY_INTEGER := 0, col_charsetid     BINARY_INTEGER := 0, col_charsetform   BINARY_INTEGER := 0, col_null_ok       BOOLEAN := TRUE); </pre> | <p>DESCRIBE_LIST describes the columns of the data table after the transformation list has been applied. A DESCRIBE_LIST is returned by the <a href="#">DESCRIBE_STACK Procedure</a>.</p> <p>The DESC_TAB2 and DESC_REC2 types are defined in the DBMS_SQL package. See "DESC_REC2 Record Type".</p> <p>The col_type field of DESC_REC2 identifies the datatype of the column. The datatype is expressed as a numeric constant that represents a built-in datatype. For example, a 1 indicates a variable length character string. The codes for Oracle built-in datatypes are listed in <i>Oracle Database SQL Language Reference</i>. The codes for the Oracle Data Mining nested types are described in "Constants".</p> <p>The col_name field of DESC_REC2 identifies the column name. It may be populated with a column name, an alias, or an expression. If the column name is a SELECT expression, it may be very long. If the expression is longer than 30 bytes, it cannot be used in a view unless it is given an alias.</p>                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TRANSFORM_LIST</b> | <pre> TABLE OF transform_rec  TYPE transform_rec IS RECORD ( attribute_name     VARCHAR2(30), attribute_subname  VARCHAR2(4000), expression         EXPRESSION_REC, reverse_expression EXPRESSION_REC, attribute_spec     VARCHAR2(4000));  TYPE expression_rec IS RECORD ( lstmt      DBMS_SQL.VARCHAR2A, lb         BINARY_INTEGER DEFAULT 1, ub         BINARY_INTEGER DEFAULT 0);  TYPE varchar2a IS TABLE OF VARCHAR2(32767) INDEX BY BINARY_INTEGER; </pre>                                                                                                         | <p>TRANSFORM_LIST is a list of transformations that can be embedded in a model. A TRANSFORM_LIST is accepted as an argument by the <a href="#">CREATE_MODEL Procedure</a>.</p> <p>Each element in a TRANSFORM_LIST is a TRANSFORM_REC that specifies how to transform a single attribute. The attribute_name is a column name. The attribute_subname is the nested attribute name if the column is nested, otherwise attribute_subname is null.</p> <p>The expression field holds a SQL expression for transforming the attribute. See "About Transformation Lists" for an explanation of reverse expressions.</p> <p>The attribute_spec field can be used to cause the attribute to be handled in a specific way during the model build. See <a href="#">Table 49-33</a> for details.</p> <p>The expressions in a TRANSFORM_REC have type EXPRESSION_REC. The lstmt field stores a VARCHAR2A, which is a table of VARCHAR2(32767). The VARCHAR2A datatype allows transformation expressions to be very long, as they can be broken up across multiple rows of VARCHAR2. The VARCHAR2A type is defined in the DBMS_SQL package. See "VARCHAR2A Table Type".</p> <p>The ub (upper bound) and lb (lower bound) fields indicate how many rows there are in the VARCHAR2A table. If ub &lt; lb (default) the EXPRESSION_REC is empty; if lb=ub=1 there is one row; if lb=1 and ub=2 there are 2 rows, and so on.</p> |

## 49.5 DBMS\_DATA\_MINING\_TRANSFORM Constants

DBMS\_DATA\_MINING\_TRANSFORM defines the constants described in the following table.

**Table 49-2 Constants in DBMS\_DATA\_MINING\_TRANSFORM**

| Constant          | Value  | Description                                                                                                                                                                                                                                                                                                |
|-------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*Oracle Data Mining User's Guide* for information about nested data in Oracle Data Mining

## 49.6 Summary of DBMS\_DATA\_MINING\_TRANSFORM Subprograms

This table lists the DBMS\_DATA\_MINING\_TRANSFORM subprograms in alphabetical order and briefly describes them.

**Table 49-3 DBMS\_DATA\_MINING\_TRANSFORM Package Subprograms**

| Subprogram                               | Purpose                                                           |
|------------------------------------------|-------------------------------------------------------------------|
| <a href="#">CREATE_BIN_CAT Procedure</a> | Creates a transformation definition table for categorical binning |
| <a href="#">CREATE_BIN_NUM Procedure</a> | Creates a transformation definition table for numerical binning   |
| <a href="#">CREATE_CLIP Procedure</a>    | Creates a transformation definition table for clipping            |
| <a href="#">CREATE_COL_REM Procedure</a> | Creates a transformation definition table for column removal      |

**Table 49-3 (Cont.) DBMS\_DATA\_MINING\_TRANSFORM Package Subprograms**

| Subprogram                               | Purpose                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------|
| CREATE_MISS_CAT Procedure                | Creates a transformation definition table for categorical missing value treatment                    |
| CREATE_MISS_NUM Procedure                | Creates a transformation definition table for numerical missing values treatment                     |
| CREATE_NORM_LIN Procedure                | Creates a transformation definition table for linear normalization                                   |
| DESCRIBE_STACK Procedure                 | Describes the transformation list                                                                    |
| GET_EXPRESSION Function                  | Returns a VARCHAR2 chunk from a transformation expression                                            |
| INSERT_AUTOBIN_NUM_EQWIDT<br>H Procedure | Inserts numeric automatic equi-width binning definitions in a transformation definition table        |
| INSERT_BIN_CAT_FREQ<br>Procedure         | Inserts categorical frequency-based binning definitions in a transformation definition table         |
| INSERT_BIN_NUM_EQWIDTH<br>Procedure      | Inserts numeric equi-width binning definitions in a transformation definition table                  |
| INSERT_BIN_NUM_QTILE<br>Procedure        | Inserts numeric quantile binning expressions in a transformation definition table                    |
| INSERT_BIN_SUPER Procedure               | Inserts supervised binning definitions in numerical and categorical transformation definition tables |
| INSERT_CLIP_TRIM_TAIL<br>Procedure       | Inserts numerical trimming definitions in a transformation definition table                          |
| INSERT_CLIP_WINSOR_TAIL<br>Procedure     | Inserts numerical winsorizing definitions in a transformation definition table                       |
| INSERT_MISS_CAT_MODE<br>Procedure        | Inserts categorical missing value treatment definitions in a transformation definition table         |
| INSERT_MISS_NUM_MEAN<br>Procedure        | Inserts numerical missing value treatment definitions in a transformation definition table           |
| INSERT_NORM_LIN_MINMAX<br>Procedure      | Inserts linear min-max normalization definitions in a transformation definition table                |
| INSERT_NORM_LIN_SCALE<br>Procedure       | Inserts linear scale normalization definitions in a transformation definition table                  |
| INSERT_NORM_LIN_ZSCORE<br>Procedure      | Inserts linear zscore normalization definitions in a transformation definition table                 |
| SET_EXPRESSION Procedure                 | Adds a VARCHAR2 chunk to an expression                                                               |
| SET_TRANSFORM Procedure                  | Adds a transformation record to a transformation list                                                |
| STACK_BIN_CAT Procedure                  | Adds a categorical binning expression to a transformation list                                       |
| STACK_BIN_NUM Procedure                  | Adds a numerical binning expression to a transformation list                                         |
| STACK_CLIP Procedure                     | Adds a clipping expression to a transformation list                                                  |
| STACK_COL_REM Procedure                  | Adds a column removal expression to a transformation list                                            |
| STACK_MISS_CAT Procedure                 | Adds a categorical missing value treatment expression to a transformation list                       |
| STACK_MISS_NUM Procedure                 | Adds a numerical missing value treatment expression to a transformation list                         |
| STACK_NORM_LIN Procedure                 | Adds a linear normalization expression to a transformation list                                      |
| XFORM_BIN_CAT Procedure                  | Creates a view of the data table with categorical binning transformations                            |

**Table 49-3 (Cont.) DBMS\_DATA\_MINING\_TRANSFORM Package Subprograms**

## 49.6.1 CREATE\_BIN\_CAT Procedure

This procedure creates a transformation definition table for categorical binning.

The columns are described in the following table.

**Table 49-4 Columns in a Transformation Definition Table for Categorical Binning**

| Name | Datatype       | Description                                                                                                                                                                                           |
|------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col  | VARCHAR2(30)   | Name of a column of categorical data.<br>If the column is not nested, the column name is also the attribute name. For information about attribute names, see <i>Oracle Data Mining User's Guide</i> . |
| att  | VARCHAR2(4000) | The attribute subname if <i>col</i> is a nested column.<br>If <i>col</i> is nested, the attribute name is <i>col.att</i> . If <i>col</i> is not nested, <i>att</i> is null.                           |
| val  | VARCHAR2(4000) | Values of the attribute                                                                                                                                                                               |
| bin  | VARCHAR2(4000) | Bin assignments for the values                                                                                                                                                                        |

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_BIN_CAT (  
    bin_table_name      IN VARCHAR2,  
    bin_schema_name     IN VARCHAR2 DEFAULT NULL );
```

## Parameters

**Table 49-5 CREATE\_BIN\_CAT Procedure Parameters**

| Parameter                    | Description                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------|
| <code>bin_table_name</code>  | Name of the transformation definition table to be created                                      |
| <code>bin_schema_name</code> | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used. |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about categorical data.
2. See "[Nested Data Transformations](#)" for information about transformation definition tables and nested data.
3. You can use the following procedures to populate the transformation definition table:
  - [INSERT\\_BIN\\_CAT\\_FREQ Procedure](#) — frequency-based binning
  - [INSERT\\_BIN\\_SUPER Procedure](#) — supervised binning

### See Also:

"Binning" in [DBMS\\_DATA\\_MINING\\_TRANSFORM Overview](#)  
"Operational Notes"

## Examples

The following statement creates a table called `bin_cat_xtbl` in the current schema. The table has columns that can be populated with bin assignments for categorical attributes.

```
BEGIN
  DBMS_DATA_MINING_TRANSFORM.CREATE_BIN_CAT('bin_cat_xtbl');
END;
/
DESCRIBE bin_cat_xtbl
```

| Name | Null? | Type            |
|------|-------|-----------------|
| COL  |       | VARCHAR2 (30)   |
| ATT  |       | VARCHAR2 (4000) |
| VAL  |       | VARCHAR2 (4000) |
| BIN  |       | VARCHAR2 (4000) |

## 49.6.2 CREATE\_BIN\_NUM Procedure

This procedure creates a transformation definition table for numerical binning.

The columns are described in the following table.

**Table 49-6 Columns in a Transformation Definition Table for Numerical Binning**

| Name | Datatype       | Description                                                                                                                                                                                         |
|------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col  | VARCHAR2(30)   | Name of a column of numerical data.<br>If the column is not nested, the column name is also the attribute name. For information about attribute names, see <i>Oracle Data Mining User's Guide</i> . |
| att  | VARCHAR2(4000) | The attribute subname if <i>col</i> is a nested column.<br>If <i>col</i> is nested, the attribute name is <i>col.att</i> . If <i>col</i> is not nested, <i>att</i> is null.                         |
| val  | NUMBER         | Values of the attribute                                                                                                                                                                             |
| bin  | VARCHAR2(4000) | Bin assignments for the values                                                                                                                                                                      |

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_BIN_NUM (
    bin_table_name    IN VARCHAR2,
    bin_schema_name   IN VARCHAR2 DEFAULT NULL );
```

### Parameters

**Table 49-7 CREATE\_BIN\_NUM Procedure Parameters**

| Parameter       | Description                                                                              |
|-----------------|------------------------------------------------------------------------------------------|
| bin_table_name  | Name of the transformation definition table to be created                                |
| bin_schema_name | Schema of <i>bin_table_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. See "[Nested Data Transformations](#)" for information about transformation definition tables and nested data.
3. You can use the following procedures to populate the transformation definition table:
  - [INSERT\\_AUTOBIN\\_NUM\\_EQWIDTH Procedure](#) — automatic equi-width binning
  - [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) — user-specified equi-width binning
  - [INSERT\\_BIN\\_NUM\\_QTILE Procedure](#) — quantile binning
  - [INSERT\\_BIN\\_SUPER Procedure](#) — supervised binning

#### See Also:

"Binning" in [DBMS\\_DATA\\_MINING\\_TRANSFORM Overview](#)  
"Operational Notes"

## Examples

The following statement creates a table called `bin_num_xtbl` in the current schema. The table has columns that can be populated with bin assignments for numerical attributes.

```
BEGIN
  DBMS_DATA_MINING_TRANSFORM.CREATE_BIN_NUM('bin_num_xtbl');
END;
/
```

```
DESCRIBE bin_num_xtbl
```

| Name | Null? | Type            |
|------|-------|-----------------|
| COL  |       | VARCHAR2 (30)   |
| ATT  |       | VARCHAR2 (4000) |
| VAL  |       | NUMBER          |
| BIN  |       | VARCHAR2 (4000) |

## 49.6.3 CREATE\_CLIP Procedure

This procedure creates a transformation definition table for clipping or winsorizing to minimize the effect of outliers.

The columns are described in the following table.

**Table 49-8 Columns in a Transformation Definition Table for Clipping or Winsorizing**

| Name              | Datatype        | Description                                                                                                                                                                                                                                                                       |
|-------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col</code>  | VARCHAR2 (30)   | Name of a column of numerical data.<br>If the column is not nested, the column name is also the attribute name. For information about attribute names, see <i>Oracle Data Mining User's Guide</i> .                                                                               |
| <code>att</code>  | VARCHAR2 (4000) | The attribute subname if <code>col</code> is a nested column of <code>DM_NESTED_NUMERICALS</code> . If <code>col</code> is nested, the attribute name is <code>col.att</code> .<br>If <code>col</code> is not nested, <code>att</code> is null.                                   |
| <code>lcut</code> | NUMBER          | The lowest typical value for the attribute.<br>If the attribute values were plotted on an xy axis, <code>lcut</code> would be the left-most boundary of the range of values considered typical for this attribute.<br>Any values to the left of <code>lcut</code> are outliers.   |
| <code>lval</code> | NUMBER          | Value assigned to an outlier to the left of <code>lcut</code>                                                                                                                                                                                                                     |
| <code>rcut</code> | NUMBER          | The highest typical value for the attribute<br>If the attribute values were plotted on an xy axis, <code>rcut</code> would be the right-most boundary of the range of values considered typical for this attribute.<br>Any values to the right of <code>rcut</code> are outliers. |
| <code>rval</code> | NUMBER          | Value assigned to an outlier to the right of <code>rcut</code>                                                                                                                                                                                                                    |

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_CLIP (
  clip_table_name   IN VARCHAR2,
  clip_schema_name  IN VARCHAR2 DEFAULT NULL );
```

## Parameters

**Table 49-9 CREATE\_CLIP Procedure Parameters**

| Parameter                     | Description                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------|
| <code>clip_table_name</code>  | Name of the transformation definition table to be created                                       |
| <code>clip_schema_name</code> | Schema of <code>clip_table_name</code> . If no schema is specified, the current schema is used. |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. See "[Nested Data Transformations](#)" for information about transformation definition tables and nested data.
3. You can use the following procedures to populate the transformation definition table:
  - [INSERT\\_CLIP\\_TRIM\\_TAIL Procedure](#) — replaces outliers with nulls
  - [INSERT\\_CLIP\\_WINSOR\\_TAIL Procedure](#) — replaces outliers with an average value

### See Also:

"Outlier Treatment" in [DBMS\\_DATA\\_MINING\\_TRANSFORM Overview](#)  
 "Operational Notes"

## Examples

The following statement creates a table called `clip_xtbl` in the current schema. The table has columns that can be populated with clipping instructions for numerical attributes.

```
BEGIN
  DBMS_DATA_MINING_TRANSFORM.CREATE_CLIP('clip_xtbl');
END;
/
```

```
DESCRIBE clip_xtbl
```

| Name | Null? | Type            |
|------|-------|-----------------|
| COL  |       | VARCHAR2 (30)   |
| ATT  |       | VARCHAR2 (4000) |
| LCUT |       | NUMBER          |
| LVAL |       | NUMBER          |
| RCUT |       | NUMBER          |
| RVAL |       | NUMBER          |

## 49.6.4 CREATE\_COL\_REM Procedure

This procedure creates a transformation definition table for removing columns from the data table.

The columns are described in the following table.

**Table 49-10 Columns in a Transformation Definition Table for Column Removal**

| Name | Datatype       | Description                                                                                                                                                                                                         |
|------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col  | VARCHAR2(30)   | Name of a column of data.<br>If the column is not nested, the column name is also the attribute name.<br>For information about attribute names, see <i>Oracle Data Mining User's Guide</i> .                        |
| att  | VARCHAR2(4000) | The attribute subname if <i>col</i> is nested (DM_NESTED_NUMERICALS or DM_NESTED_CATEGORICALS). If <i>col</i> is nested, the attribute name is <i>col.att</i> .<br>If <i>col</i> is not nested, <i>att</i> is null. |

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_COL_REM (
    rem_table_name          VARCHAR2,
    rem_schema_name         VARCHAR2 DEFAULT NULL );
```

### Parameters

**Table 49-11 CREATE\_COL\_REM Procedure Parameters**

| Parameter       | Description                                                                              |
|-----------------|------------------------------------------------------------------------------------------|
| rem_table_name  | Name of the transformation definition table to be created                                |
| rem_schema_name | Schema of <i>rem_table_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

1. See "[Nested Data Transformations](#)" for information about transformation definition tables and nested data.
2. See "[Operational Notes](#)".

### Examples

The following statement creates a table called *rem\_att\_xtbl* in the current schema. The table has columns that can be populated with the names of attributes to exclude from the data to be mined.

```
BEGIN
    DBMS_DATA_MINING_TRANSFORM.CREATE_COL_REM ('rem_att_xtbl');
END;
/
DESCRIBE rem_att_xtbl
```

| Name | Null? | Type           |
|------|-------|----------------|
| COL  |       | VARCHAR2(30)   |
| ATT  |       | VARCHAR2(4000) |

## 49.6.5 CREATE\_MISS\_CAT Procedure

This procedure creates a transformation definition table for replacing categorical missing values.

The columns are described in the following table.

**Table 49-12 Columns in a Transformation Definition Table for Categorical Missing Value Treatment**

| Name | Datatype       | Description                                                                                                                                                                                              |
|------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col  | VARCHAR2(30)   | Name of a column of categorical data.<br>If the column is not nested, the column name is also the attribute name.<br>For information about attribute names, see <i>Oracle Data Mining User's Guide</i> . |
| att  | VARCHAR2(4000) | The attribute subname if <i>col</i> is a nested column of DM_NESTED_CATEGORICALS. If <i>col</i> is nested, the attribute name is <i>col.att</i> .<br>If <i>col</i> is not nested, <i>att</i> is null.    |
| val  | VARCHAR2(4000) | Replacement for missing values in the attribute                                                                                                                                                          |

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_MISS_CAT (  
    miss_table_name      IN VARCHAR2,  
    miss_schema_name     IN VARCHAR2 DEFAULT NULL );
```

### Parameters

**Table 49-13 CREATE\_MISS\_CAT Procedure Parameters**

| Parameter        | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| miss_table_name  | Name of the transformation definition table to be created                                 |
| miss_schema_name | Schema of <i>miss_table_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about categorical data.
2. See "[Nested Data Transformations](#)" for information about transformation definition tables and nested data.
3. You can use the [INSERT\\_MISS\\_CAT\\_MODE Procedure](#) to populate the transformation definition table.

## Examples

The following statement creates a table called `miss_cat_xtbl` in the current schema. The table has columns that can be populated with values for missing data in categorical attributes.

```
BEGIN
    DBMS_DATA_MINING_TRANSFORM.CREATE_MISS_CAT('miss_cat_xtbl');
END;
/

DESCRIBE miss_cat_xtbl
Name                                         Null?    Type
-----
COL                                         VARCHAR2(30)
ATT                                         VARCHAR2(4000)
VAL                                         VARCHAR2(4000)
```

## 49.6.6 CREATE\_MISS\_NUM Procedure

This procedure creates a transformation definition table for replacing numerical missing values.

The columns are described in [Table 49-14](#).

**Table 49-14 Columns in a Transformation Definition Table for Numerical Missing Value Treatment**

| Name | Datatype       | Description                                                                                                                                                                                                       |
|------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col  | VARCHAR2(30)   | Name of a column of numerical data.<br>If the column is not nested, the column name is also the attribute name. For information about attribute names, see <i>Oracle Data Mining User's Guide</i> .               |
| att  | VARCHAR2(4000) | The attribute subname if <i>col</i> is a nested column of <code>DM_NESTED_NUMERICALS</code> . If <i>col</i> is nested, the attribute name is <i>col.att</i> .<br>If <i>col</i> is not nested, <i>att</i> is null. |
| val  | NUMBER         | Replacement for missing values in the attribute                                                                                                                                                                   |

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_MISS_NUM (
    miss_table_name      IN VARCHAR2,
    miss_schema_name     IN VARCHAR2 DEFAULT NULL );
```

### Parameters

**Table 49-15 CREATE\_MISS\_NUM Procedure Parameters**

| Parameter        | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| miss_table_name  | Name of the transformation definition table to be created                                 |
| miss_schema_name | Schema of <i>miss_table_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. See ["Nested Data Transformations"](#) for information about transformation definition tables and nested data.
3. You can use the [INSERT\\_MISS\\_NUM\\_MEAN Procedure](#) to populate the transformation definition table.

#### See Also:

"Missing Value Treatment" in [DBMS\\_DATA\\_MINING\\_TRANSFORM Overview](#)  
 "Operational Notes"

### Example

The following statement creates a table called `miss_num_xtbl` in the current schema. The table has columns that can be populated with values for missing data in numerical attributes.

```
BEGIN
    DBMS_DATA_MINING_TRANSFORM.CREATE_MISS_NUM('miss_num_xtbl');
END;
/
```

```
DESCRIBE miss_num_xtbl
```

| Name | Null? | Type            |
|------|-------|-----------------|
| COL  |       | VARCHAR2 (30)   |
| ATT  |       | VARCHAR2 (4000) |
| VAL  |       | NUMBER          |

## 49.6.7 CREATE\_NORM\_LIN Procedure

This procedure creates a transformation definition table for linear normalization.

The columns are described in [Table 49-16](#).

**Table 49-16 Columns in a Transformation Definition Table for Linear Normalization**

| Name  | Datatype        | Description                                                                                                                                                                                                       |
|-------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| col   | VARCHAR2 (30)   | Name of a column of numerical data.<br>If the column is not nested, the column name is also the attribute name. For information about attribute names, see <i>Oracle Data Mining User's Guide</i> .               |
| att   | VARCHAR2 (4000) | The attribute subname if <i>col</i> is a nested column of <code>DM_NESTED_NUMERICALS</code> . If <i>col</i> is nested, the attribute name is <i>col.att</i> .<br>If <i>col</i> is not nested, <i>att</i> is null. |
| shift | NUMBER          | A constant to subtract from the attribute values                                                                                                                                                                  |
| scale | NUMBER          | A constant by which to divide the shifted values                                                                                                                                                                  |

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.CREATE_NORM_LIN (
    norm_table_name      IN VARCHAR2,
    norm_schema_name     IN VARCHAR2 DEFAULT NULL );
```

## Parameters

**Table 49-17 CREATE\_NORM\_LIN Procedure Parameters**

| Parameter        | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| norm_table_name  | Name of the transformation definition table to be created                                 |
| norm_schema_name | Schema of <i>norm_table_name</i> . If no schema is specified, the current schema is used. |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. See ["Nested Data Transformations"](#) for information about transformation definition tables and nested data.
3. You can use the following procedures to populate the transformation definition table:
  - [INSERT\\_NORM\\_LIN\\_MINMAX Procedure](#) — Uses linear min-max normalization
  - [INSERT\\_NORM\\_LIN\\_SCALE Procedure](#) — Uses linear scale normalization
  - [INSERT\\_NORM\\_LIN\\_ZSCORE Procedure](#) — Uses linear zscore normalization

### See Also:

"Linear Normalization" in [DBMS\\_DATA\\_MINING\\_TRANSFORM Overview](#)  
"Operational Notes"

## Examples

The following statement creates a table called `norm_xtbl` in the current schema. The table has columns that can be populated with shift and scale values for normalizing numerical attributes.

```
BEGIN
    DBMS_DATA_MINING_TRANSFORM.CREATE_NORM_LIN('norm_xtbl');
END;
/

DESCRIBE norm_xtbl
```

| Name  | Null? | Type            |
|-------|-------|-----------------|
| COL   |       | VARCHAR2 (30)   |
| ATT   |       | VARCHAR2 (4000) |
| SHIFT |       | NUMBER          |
| SCALE |       | NUMBER          |

## 49.6.8 DESCRIBE\_STACK Procedure

This procedure describes the columns of the data table after a list of transformations has been applied.

Only the columns that are specified in the transformation list are transformed. The remaining columns in the data table are included in the output without changes.

To create a view of the data table after the transformations have been applied, use the [XFORM\\_STACK Procedure](#).

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.DESCRIBE_STACK (
    xform_list          IN  TRANSFORM_LIST,
    data_table_name     IN  VARCHAR2,
    describe_list       OUT DESCRIBE_LIST,
    data_schema_name    IN  VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-18 DESCRIBE\_STACK Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xform_list       | A list of transformations. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type.                                                                                        |
| data_table_name  | Name of the table containing the data to be transformed                                                                                                                                               |
| describe_list    | Descriptions of the columns in the data table after the transformations specified in xform_list have been applied. See <a href="#">Table 49-1</a> for a description of the DESCRIBE_LIST object type. |
| data_schema_name | Schema of data_table_name. If no schema is specified, the current schema is used.                                                                                                                     |

### Usage Notes

See "[Operational Notes](#)" for information about transformation lists and embedded transformations.

### Examples

This example shows the column name and datatype, the column name length, and the column maximum length for the view dmuser.cust\_info after the transformation list has been applied. All the transformations are user-specified. The results of DESCRIBE\_STACK do not include one of the columns in the original table, because the SET\_TRANSFORM procedure sets that column to NULL.

```
CREATE OR REPLACE VIEW cust_info AS
    SELECT a.cust_id, c.country_id, c.cust_year_of_birth,
    CAST(COLLECT(DM_Nested_Numerical(
        b.prod_name, 1))
    AS DM_Nested_Numericals) custprods
    FROM sh.sales a, sh.products b, sh.customers c
    WHERE a.prod_id = b.prod_id AND
        a.cust_id=c.cust_id and
        a.cust_id between 100001 AND 105000
    GROUP BY a.cust_id, country_id, cust_year_of_birth;
```

```

describe cust_info
Name                                         Null?    Type
-----

## 49.6.9 GET\_EXPRESSION Function

This function returns a row from a `VARCHAR2` array that stores a transformation expression. The array is built by calls to the `SET_EXPRESSION` Procedure.

The array can be used for specifying SQL expressions that are too long to be used with the `SET_TRANSFORM` Procedure.

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.GET_EXPRESSION (
    expression          IN EXPRESSION_REC,
    chunk_num           IN PLS_INTEGER DEFAULT NULL);
RETURN VARCHAR2;
```

## Parameters

**Table 49-19 GET\_EXPRESSION Function Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expression</code> | <p>An expression record (<code>EXPRESSION_REC</code>) that specifies a transformation expression or a reverse transformation expression for an attribute. Each expression record includes a <code>VARCHAR2</code> array and index fields for specifying upper and lower boundaries within the array.</p> <p>There are two <code>EXPRESSION_REC</code> fields within a transformation record (<code>TRANSFORM_REC</code>): one for the transformation expression; the other for the reverse transformation expression.</p> <p>See <a href="#">Table 49-1</a> for a description of the <code>EXPRESSION_REC</code> type.</p> |
| <code>chunk</code>      | A <code>VARCHAR2</code> chunk (row) to be appended to <i>expression</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Usage Notes

1. Chunk numbering starts with one. For chunks outside of the range, the return value is null. When a chunk number is null the whole expression is returned as a string. If the expression is too big, a `VALUE_ERROR` is raised.
2. See "[About Transformation Lists](#)".
3. See "[Operational Notes](#)".

## Examples

See the example for the [SET\\_EXPRESSION Procedure](#).

## Related Topics

This procedure appends the transformation instructions for an attribute to a transformation list.

## 49.6.10 INSERT\_AUTOBIN\_NUM\_EQWIDTH Procedure

This procedure performs numerical binning and inserts the transformation definitions in a transformation definition table. The procedure identifies the minimum and maximum values and computes the bin boundaries at equal intervals.

`INSERT_AUTOBIN_NUM_EQWIDTH` computes the number of bins separately for each column. If you want to use equi-width binning with the same number of bins for each column, use the [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#).

`INSERT_AUTOBIN_NUM_EQWIDTH` bins all the `NUMBER` and `FLOAT` columns in the data source unless you specify a list of columns to ignore.

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_AUTOBIN_NUM_EQWIDTH (
    bin_table_name      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    bin_num             IN PLS_INTEGER DEFAULT 3,
    max_bin_num         IN PLS_INTEGER DEFAULT 100,
    exclude_list        IN COLUMN_LIST DEFAULT NULL,
    round_num           IN PLS_INTEGER DEFAULT 6,
    sample_size         IN PLS_INTEGER DEFAULT 50000,
    bin_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL,
    rem_table_name      IN VARCHAR2 DEFAULT NULL,
    rem_schema_name     IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-20 INSERT\_AUTOBIN\_NUM\_EQWIDTH Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |               |     |        |     |                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------------|-----|--------|-----|-----------------|
| bin_table_name  | <p>Name of the transformation definition table for numerical binning. You can use the <a href="#">CREATE_BIN_NUM Procedure</a> to create the definition table. The following columns are required:</p> <table> <tr> <td>COL</td><td>VARCHAR2 (30)</td></tr> <tr> <td>VAL</td><td>NUMBER</td></tr> <tr> <td>BIN</td><td>VARCHAR2 (4000)</td></tr> </table> <p>CREATE_BIN_NUM creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_AUTOBIN_NUM_EQWIDTH.</p> | COL | VARCHAR2 (30) | VAL | NUMBER | BIN | VARCHAR2 (4000) |
| COL             | VARCHAR2 (30)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |     |               |     |        |     |                 |
| VAL             | NUMBER                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |               |     |        |     |                 |
| BIN             | VARCHAR2 (4000)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |               |     |        |     |                 |
| data_table_name | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |               |     |        |     |                 |
| bin_num         | <p>Minimum number of bins. If <i>bin_num</i> is 0 or NULL, it is ignored.</p> <p>The default value of <i>bin_num</i> is 3.</p>                                                                                                                                                                                                                                                                                                                                                                                                |     |               |     |        |     |                 |
| max_bin_num     | <p>Maximum number of bins. If <i>max_bin_num</i> is 0 or NULL, it is ignored.</p> <p>The default value of <i>max_bin_num</i> is 100.</p>                                                                                                                                                                                                                                                                                                                                                                                      |     |               |     |        |     |                 |
| exclude_list    | <p>List of numerical columns to be excluded from the binning process. If you do not specify <i>exclude_list</i>, all numerical columns in the data source are binned.</p> <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                                                                                                   |     |               |     |        |     |                 |
| round_num       | <p>Specifies how to round the number in the VAL column of the transformation definition table.</p> <p>When <i>round_num</i> is positive, it specifies the most significant digits to retain. When <i>round_num</i> is negative, it specifies the least significant digits to remove. In both cases, the result is rounded to the specified number of digits. See the Usage Notes for an example.</p> <p>The default value of <i>round_num</i> is 6.</p>                                                                       |     |               |     |        |     |                 |

**Table 49-20 (Cont.) INSERT\_AUTOBIN\_NUM\_EQWIDTH Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sample_size</code>      | Size of the data sample. If <code>sample_size</code> is less than the total number of non-NULL values in the column, then <code>sample_size</code> is used instead of the SQL COUNT function in computing the number of bins. If <code>sample_size</code> is 0 or NULL, it is ignored. See the Usage Notes.<br>The default value of <code>sample_size</code> is 50,000.                                                                           |
| <code>bin_schema_name</code>  | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                    |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                   |
| <code>rem_table_name</code>   | Name of a transformation definition table for column removal. The table must have the columns described in "CREATE_COL_REM Procedure".<br>INSERT_AUTOBIN_NUM_EQWIDTH ignores columns with all nulls or only one unique value. If you specify a value for <code>rem_table_name</code> , these columns are removed from the mining data. If you do not specify a value for <code>rem_table_name</code> , these unbinned columns remain in the data. |
| <code>rem_schema_name</code>  | Schema of <code>rem_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                    |

#### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. INSERT\_AUTOBIN\_NUM\_EQWIDTH computes the number of bins for a column based on the number of non-null values (COUNT), the maximum (MAX), the minimum (MIN), the standard deviation (STDDEV), and the constant  $C=3.49/0.9$ :  
$$N = \text{floor}(\text{power}(\text{COUNT}, 1/3) * (\text{max} - \text{min}) / (c * \text{dev}))$$
  
If the `sample_size` parameter is specified, it is used instead of COUNT.  
See *Oracle Database SQL Language Reference* for information about the COUNT, MAX, MIN, STDDEV, FLOOR, and POWER functions.
3. INSERT\_AUTOBIN\_NUM\_EQWIDTH uses absolute values to compute the number of bins. The sign of the parameters `bin_num`, `max_bin_num`, and `sample_size` has no effect on the result.
4. In computing the number of bins, INSERT\_AUTOBIN\_NUM\_EQWIDTH evaluates the following criteria in the following order:
  - a. The minimum number of bins (`bin_num`)
  - b. The maximum number of bins (`max_bin_num`)
  - c. The maximum number of bins for integer columns, calculated as the number of distinct values in the range  $\text{max} - \text{min} + 1$ .
5. The `round_num` parameter controls the rounding of column values in the transformation definition table, as follows:

**For a value of 308.162:**

|                                 |                   |
|---------------------------------|-------------------|
| when <code>round_num</code> = 1 | result is 300     |
| when <code>round_num</code> = 2 | result is 310     |
| when <code>round_num</code> = 3 | result is 308     |
| when <code>round_num</code> = 0 | result is 308.162 |

```

when round_num = -1      result is 308.16
when round_num = -2      result is 308.2

```

## Examples

In this example, `INSERT_AUTOBIN_NUM_EQWIDTH` computes the bin boundaries for the `cust_year_of_birth` column in `sh.customers` and inserts the transformations in a transformation definition table. The [STACK\\_BIN\\_NUM Procedure](#) creates a transformation list from the contents of the definition table. The [CREATE\\_MODEL Procedure](#) embeds the transformation list in a new model called `nb_model`.

The transformation and reverse transformation expressions embedded in `nb_model` are returned by the [GET\\_MODEL\\_TRANSFORMATIONS Function](#).

```

CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_year_of_birth, cust_postal_code
    FROM sh.customers;

DESCRIBE mining_data
Name                                     Null?    Type
-----
CUST_ID                                 NOT NULL NUMBER
CUST_YEAR_OF_BIRTH                     NOT NULL NUMBER(4)
CUST_POSTAL_CODE                       NOT NULL VARCHAR2(10)

BEGIN
    dbms_data_mining_transform.CREATE_BIN_NUM(
        bin_table_name => 'bin_tbl');
    dbms_data_mining_transform.INSERT_AUTOBIN_NUM_EQWIDTH (
        bin_table_name => 'bin_tbl',
        data_table_name => 'mining_data',
        bin_num         => 3,

## 49.6.11 INSERT\_BIN\_CAT\_FREQ Procedure

This procedure performs categorical binning and inserts the transformation definitions in a transformation definition table. The procedure computes the bin boundaries based on frequency.

`INSERT_BIN_CAT_FREQ` bins all the `CHAR` and `VARCHAR2` columns in the data source unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_BIN_CAT_FREQ (
    bin_table_name           IN VARCHAR2,
    data_table_name          IN VARCHAR2,
    bin_num                  IN PLS_INTEGER DEFAULT 9,
    exclude_list             IN COLUMN_LIST DEFAULT NULL,
    default_num              IN PLS_INTEGER DEFAULT 2,
    bin_support              IN NUMBER DEFAULT NULL,
    bin_schema_name          IN VARCHAR2 DEFAULT NULL,
    data_schema_name         IN VARCHAR2 DEFAULT NULL);

```

## Parameters

Table 49-21 INSERT\_BIN\_CAT\_FREQ Procedure Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bin_table_name  | <p>Name of the transformation definition table for categorical binning. You can use the <a href="#">CREATE_BIN_CAT Procedure</a> to create the definition table. The following columns are required:</p> <pre> COL      VARCHAR2 (30) VAL      VARCHAR2 (4000) BIN      VARCHAR2 (4000) </pre> <p>CREATE_BIN_CAT creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_BIN_CAT_FREQ.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| data_table_name | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| bin_num         | <p>The number of bins to fill using frequency-based binning. The total number of bins will be <i>bin_num</i>+1. The additional bin is the default bin. Classes that are not assigned to a frequency-based bin will be assigned to the default bin.</p> <p>The default binning order is from highest to lowest: the most frequently occurring class is assigned to the first bin, the second most frequently occurring class is assigned to the second bin, and so on. You can reverse the binning order by specifying a negative number for <i>bin_num</i>. The negative sign causes the binning order to be from lowest to highest.</p> <p>If the total number of distinct values (classes) in the column is less than <i>bin_num</i>, then a separate bin will be created for each value and the default bin will be empty.</p> <p>If you specify NULL or 0 for <i>bin_num</i>, no binning is performed.</p> <p>The default value of <i>bin_num</i> is 9.</p> |
| exclude_list    | <p>List of categorical columns to be excluded from the binning process. If you do not specify <i>exclude_list</i>, all categorical columns in the data source are binned.</p> <p>The format of <i>exclude_list</i> is:</p> <pre> dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln') </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| default_num     | <p>The number of class occurrences (rows of the same class) required for assignment to the default bin.</p> <p>By default, <i>default_num</i> is the minimum number of occurrences required for assignment to the default bin. For example, if <i>default_num</i> is 3 and a given class occurs only once, it will not be assigned to the default bin. You can change the occurrence requirement from minimum to maximum by specifying a negative number for <i>default_num</i>. For example, if <i>default_num</i> is -3 and a given class occurs only once, it <i>will</i> be assigned to the default bin, but a class that occurs four or more times will not be included.</p> <p>If you specify NULL or 0 for <i>default_bin</i>, there are no requirements for assignment to the default bin.</p> <p>The default value of <i>default_num</i> is 2.</p>                                                                                                     |

**Table 49-21 (Cont.) INSERT\_BIN\_CAT\_FREQ Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin_support</code>      | <p>The number of class occurrences (rows of the same class) required for assignment to a frequency-based bin. <i>bin_support</i> is expressed as a fraction of the total number of rows.</p> <p>By default, <i>bin_support</i> is the minimum percentage required for assignment to a frequency-based bin. For example, if there are twenty rows of data and you specify .2 for <i>bin_support</i>, then there must be four or more occurrences of a class (.2*20) in order for it to be assigned to a frequency-based bin. You can change <i>bin_support</i> from a minimum percentage to a maximum percentage by specifying a negative number for <i>bin_support</i>. For example, if there are twenty rows of data and you specify -.2 for <i>bin_support</i>, then there must be four or less occurrences of a class in order for it to be assigned to a frequency-based bin.</p> <p>Classes that occur less than a positive <i>bin_support</i> or more than a negative <i>bin_support</i> will be assigned to the default bin.</p> <p>If you specify NULL or 0 for <i>bin_support</i>, then there is no support requirement for frequency-based binning.</p> <p>The default value of <i>bin_support</i> is NULL.</p> |
| <code>bin_schema_name</code>  | Schema of <i>bin_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>data_schema_name</code> | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Usage Notes**

1. See *Oracle Data Mining User's Guide* for details about categorical data.
2. If values occur with the same frequency, `INSERT_BIN_CAT_FREQ` assigns them in descending order when binning is from most to least frequent, or in ascending order when binning is from least to most frequent.

**Examples**

1. In this example, `INSERT_BIN_CAT_FREQ` computes the bin boundaries for the `cust_postal_code` and `cust_city` columns in `sh.customers` and inserts the transformations in a transformation definition table. The [STACK\\_BIN\\_CAT Procedure](#) creates a transformation list from the contents of the definition table, and the [CREATE\\_MODEL Procedure](#) embeds the transformation list in a new model called `nb_model`.

The transformation and reverse transformation expressions embedded in `nb_model` are returned by the [GET\\_MODEL\\_TRANSFORMATIONS Function](#).

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_postal_code, cust_city
  FROM sh.customers;
```

```
DESCRIBE mining_data
```

| Name               | Null?    | Type         |
|--------------------|----------|--------------|
| CUST_ID            | NOT NULL | NUMBER       |
| CUST_YEAR_OF_BIRTH | NOT NULL | NUMBER(4)    |
| CUST_POSTAL_CODE   | NOT NULL | VARCHAR2(10) |
| CUST_CITY          | NOT NULL | VARCHAR2(30) |

```

BEGIN
    dbms_data_mining_transform.CREATE_BIN_CAT(
        bin_table_name => 'bin_tbl_1');
    dbms_data_mining_transform.INSERT_BIN_CAT_FREQ (
        bin_table_name => 'bin_tbl_1',
        data_table_name => 'mining_data',
        bin_num         => 4);
END;
/

column col format a18
column val format a15
column bin format a10
SELECT col, val, bin
       FROM bin_tbl_1
       ORDER BY col ASC, bin ASC;

```

| COL              | VAL         | BIN   |

DECLARE
    city_xform    dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.STACK_BIN_CAT (
        bin_table_name      => 'bin_tbl_1',
        xform_list          => city_xform);
    dbms_data_mining.CREATE_MODEL(
        model_name           => 'nb_model',
        mining_function       => dbms_data_mining.classification,
        data_table_name      => 'mining_data',
        case_id_column_name  => 'cust_id',
        target_column_name   => 'cust_city',
        settings_table_name  => null,
        data_schema_name     => null,
        settings_schema_name => null,
        xform_list           => city_xform);
END;
/

SELECT attribute_name
       FROM TABLE(dbms_data_mining.GET_MODEL_TRANSFORMATIONS('nb_model'));

ATTRIBUTE_NAME
-----
CUST_CITY
CUST_POSTAL_CODE

SELECT expression
       FROM TABLE(dbms_data_mining.GET_MODEL_TRANSFORMATIONS('nb_model'));

EXPRESSION

```

```

-----
DECODE("CUST_CITY", 'Greenwich', '2', 'Killarney', '3', 'Los Angeles', '1',
'Montara', '4', NULL, NULL, '5')
DECODE("CUST_POSTAL_CODE", '38082', '1', '55787', '3', '63736', '2', '78558', '4', NULL, NULL, '5')

SELECT reverse_expression
      FROM TABLE(dbms_data_mining.GET_MODEL_TRANSFORMATIONS('nb_model'));

REVERSE_EXPRESSION
-----
DECODE("CUST_CITY", '2', ''Greenwich'', '3', ''Killarney'', '1',
''Los Angeles'', '4', ''Montara'', NULL, 'NULL', '5', 'DEFAULT')
DECODE("CUST_POSTAL_CODE", '1', ''38082'', '3', ''55787'', '2', ''63736'',
'4', ''78558'', NULL, 'NULL', '5', 'DEFAULT')

```

2. The binning order in example 1 is from most frequent to least frequent. The following example shows reverse order binning (least frequent to most frequent). The binning order is reversed by setting *bin\_num* to -4 instead of 4.

```

BEGIN
    dbms_data_mining_transform.CREATE_BIN_CAT(
        bin_table_name => 'bin_tbl_reverse');
    dbms_data_mining_transform.INSERT_BIN_CAT_FREQ (
        bin_table_name => 'bin_tbl_reverse',
        data_table_name => 'mining_data',
        bin_num         => -4);
END;
/

column col format a20
SELECT col, val, bin
      FROM bin_tbl_reverse
      ORDER BY col ASC, bin ASC;

```

## 49.6.12 INSERT\_BIN\_NUM\_EQWIDTH Procedure

This procedure performs numerical binning and inserts the transformation definitions in a transformation definition table. The procedure identifies the minimum and maximum values and computes the bin boundaries at equal intervals.

INSERT\_BIN\_NUM\_EQWIDTH computes a specified number of bins (*n*) and assigns  $(max-min)/n$  values to each bin. The number of bins is the same for each column. If you want to use equi-width binning, but you want the number of bins to be calculated on a per-column basis, use the [INSERT\\_AUTOBIN\\_NUM\\_EQWIDTH Procedure](#).

INSERT\_BIN\_NUM\_EQWIDTH bins all the NUMBER and FLOAT columns in the data source unless you specify a list of columns to ignore.

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_BIN_NUM_EQWIDTH (
    bin_table_name      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    bin_num             IN PLS_INTEGER DEFAULT 10,
    exclude_list        IN COLUMN_LIST DEFAULT NULL,
    round_num           IN PLS_INTEGER DEFAULT 6,
    bin_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-22 INSERT\_BIN\_NUM\_EQWIDTH Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bin_table_name   | <p>Name of the transformation definition table for numerical binning. You can use the <a href="#">CREATE_BIN_NUM Procedure</a> to create the definition table. The following columns are required:</p> <pre>COL      VARCHAR2(30) VAL      NUMBER BIN      VARCHAR2(4000)</pre> <p>CREATE_BIN_NUM creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_BIN_NUM_EQWIDTH.</p>         |
| data_table_name  | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                 |
| bin_num          | <p>Number of bins. No binning occurs if <i>bin_num</i> is 0 or NULL.</p> <p>The default number of bins is 10.</p>                                                                                                                                                                                                                                                                                                                                       |
| exclude_list     | <p>List of numerical columns to be excluded from the binning process. If you do not specify <i>exclude_list</i>, all numerical columns in the data source are binned.</p> <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                             |
| round_num        | <p>Specifies how to round the number in the VAL column of the transformation definition table.</p> <p>When <i>round_num</i> is positive, it specifies the most significant digits to retain. When <i>round_num</i> is negative, it specifies the least significant digits to remove. In both cases, the result is rounded to the specified number of digits. See the Usage Notes for an example.</p> <p>The default value of <i>round_num</i> is 6.</p> |
| bin_schema_name  | Schema of <i>bin_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                |
| data_schema_name | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                               |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.

2. The `round_num` parameter controls the rounding of column values in the transformation definition table, as follows:

**For a value of 308.162:**

|                                  |                   |
|----------------------------------|-------------------|
| when <code>round_num</code> = 1  | result is 300     |
| when <code>round_num</code> = 2  | result is 310     |
| when <code>round_num</code> = 3  | result is 308     |
| when <code>round_num</code> = 0  | result is 308.162 |
| when <code>round_num</code> = -1 | result is 308.16  |
| when <code>round_num</code> = -2 | result is 308.2   |

3. `INSERT_BIN_NUM_EQWIDTH` ignores columns with all NULL values or only one unique value.

### Examples

In this example, `INSERT_BIN_NUM_EQWIDTH` computes the bin boundaries for the `affinity_card` column in `mining_data_build` and inserts the transformations in a transformation definition table. The [STACK\\_BIN\\_NUM Procedure](#) creates a transformation list from the contents of the definition table. The [CREATE\\_MODEL Procedure](#) embeds the transformation list in a new model called `glm_model`.

The transformation and reverse transformation expressions embedded in `glm_model` are returned by the [GET\\_MODEL\\_TRANSFORMATIONS Function](#).

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_income_level, cust_gender, affinity_card
    FROM mining_data_build;
```

```
DESCRIBE mining_data
```

| Name              | Null?    | Type         |
|-------------------|----------|--------------|
| CUST_ID           | NOT NULL | NUMBER       |
| CUST_INCOME_LEVEL |          | VARCHAR2(30) |
| CUST_GENDER       |          | VARCHAR2(1)  |
| AFFINITY_CARD     |          | NUMBER(10)   |

```
BEGIN
    dbms_data_mining_transform.CREATE_BIN_NUM(
        bin_table_name => 'bin_tbl');

## 49.6.13 INSERT\_BIN\_NUM\_QTILE Procedure

This procedure performs numerical binning and inserts the transformation definitions in a transformation definition table. The procedure calls the SQL `NTILE` function to order the data and divide it equally into the specified number of bins (quantiles).

`INSERT_BIN_NUM_QTILE` bins all the `NUMBER` and `FLOAT` columns in the data source unless you specify a list of columns to ignore.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_BIN_NUM_QTILE (
    bin_table_name      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    bin_num             IN PLS_INTEGER DEFAULT 10,
    exclude_list        IN COLUMN_LIST DEFAULT NULL,
    bin_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-23** INSERT\_BIN\_NUM\_QTILE Procedure Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |               |     |        |     |                 |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------------|-----|--------|-----|-----------------|
| <code>bin_table_name</code>   | <p>Name of the transformation definition table for numerical binning. You can use the <a href="#">CREATE_BIN_NUM Procedure</a> to create the definition table. | <code>bin_num</code>          | <p>Number of bins. No binning occurs if <code>bin_num</code> is 0 or <code>NULL</code>. The default number of bins is 10.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |               |     |        |     |                 |
| <code>exclude_list</code>     | <p>List of numerical columns to be excluded from the binning process. If you do not specify <code>exclude_list</code>, all numerical columns in the data source are binned.</p> <p>The format of <code>exclude_list</code> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                                                                                                                        |     |               |     |        |     |                 |
| <code>bin_schema_name</code>  | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |     |               |     |        |     |                 |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |               |     |        |     |                 |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.

2. After dividing the data into quantiles, the `NTILE` function distributes any remainder values one for each quantile, starting with the first. See *Oracle Database SQL Language Reference* for details.
3. Columns with all `NULL` values are ignored by `INSERT_BIN_NUM_QTILE`.

### Examples

In this example, `INSERT_BIN_NUM_QTILE` computes the bin boundaries for the `cust_year_of_birth` and `cust_credit_limit` columns in `sh.customers` and inserts the transformations in a transformation definition table. The [STACK\\_BIN\\_NUM Procedure](#) creates a transformation list from the contents of the definition table.

The SQL expression that computes the transformation is shown in `STACK_VIEW`. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_year_of_birth, cust_credit_limit, cust_city
    FROM sh.customers;
```

```
DESCRIBE mining_data
```

| Name               | Null?    | Type         |
|--------------------|----------|--------------|
| CUST_ID            | NOT NULL | NUMBER       |
| CUST_YEAR_OF_BIRTH | NOT NULL | NUMBER(4)    |
| CUST_CREDIT_LIMIT  |          | NUMBER       |
| CUST_CITY          | NOT NULL | VARCHAR2(30) |

```

## 49.6.14 INSERT\_BIN\_SUPER Procedure

This procedure performs numerical and categorical binning and inserts the transformation definitions in transformation definition tables. The procedure computes bin boundaries based on intrinsic relationships between predictors and a target.

INSERT\_BIN\_SUPER uses an intelligent binning technique known as **supervised binning**. It builds a single-predictor decision tree and derives the bin boundaries from splits within the tree.

INSERT\_BIN\_SUPER bins all the VARCHAR2, CHAR, NUMBER, and FLOAT columns in the data source unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_BIN_SUPER (
    num_table_name          IN VARCHAR2,

| data_table_name    | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |               |     |                 |     |                 |
| target_column_name | Name of a column to be used as the target for the decision tree models                                                                                                                                                                                                                                                                                                                                                                                                                                                     |     |               |     |                 |     |                 |
| max_bin_num        | The maximum number of bins. The default is 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |     |               |     |                 |     |                 |
| exclude_list       | <p>List of columns to be excluded from the binning process. If you do not specify <i>exclude_list</i>, all numerical and categorical columns in the data source are binned.</p> <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                                                                                          |     |               |     |                 |     |                 |
| num_schema_name    | Schema of <i>num_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |               |     |                 |     |                 |
| cat_schema_name    | Schema of <i>cat_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |               |     |                 |     |                 |
| data_schema_name   | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |               |     |                 |     |                 |
| rem_table_name     | Name of a column removal definition table. The table must have the columns described in " <a href="#">CREATE_COL_REM Procedure</a> ". You can use CREATE_COL_REM to create the table. See Usage Notes.                                                                                                                                                                                                                                                                                                                     |     |               |     |                 |     |                 |
| rem_schema_name    | Schema of <i>rem_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |               |     |                 |     |                 |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical and categorical data.

2. Columns that have no significant splits are not binned. You can remove the unbinned columns from the mining data by specifying a column removal definition table. If you do not specify a column removal definition table, the unbinned columns remain in the mining data.
3. See *Oracle Data Mining Concepts* to learn more about decision trees in Oracle Data Mining

### Examples

In this example, `INSERT_BIN_SUPER` computes the bin boundaries for predictors of `cust_credit_limit` and inserts the transformations in transformation definition tables. One predictor is numerical, the other is categorical. (`INSERT_BIN_SUPER` determines that the `cust_postal_code` column is not a significant predictor.) `STACK` procedures create transformation lists from the contents of the definition tables.

The SQL expressions that compute the transformations are shown in the views `MINING_DATA_STACK_NUM` and `MINING_DATA_STACK_CAT`. The views are for display purposes only; they cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_year_of_birth, cust_marital_status,
           cust_postal_code, cust_credit_limit
    FROM sh.customers;
```

```
DESCRIBE mining_data

## 49.6.15 INSERT\_CLIP\_TRIM\_TAIL Procedure

This procedure replaces numeric outliers with nulls and inserts the transformation definitions in a transformation definition table.

INSERT\_CLIP\_TRIM\_TAIL computes the boundaries of the data based on a specified percentage. It removes the values that fall outside the boundaries (tail values) from the data. If you wish to replace the tail values instead of removing them, use the [INSERT\\_CLIP\\_WINSOR\\_TAIL Procedure](#).

INSERT\_CLIP\_TRIM\_TAIL clips all the NUMBER and FLOAT columns in the data source unless you specify a list of columns to ignore.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_CLIP_TRIM_TAIL (
    clip_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    tail_frac            IN NUMBER DEFAULT 0.025,
    exclude_list         IN COLUMN_LIST DEFAULT NULL,
    clip_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-25 INSERT\_CLIP\_TRIM\_TAIL Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clip_table_name | Name of the transformation definition table for numerical clipping. You can use the <a href="#">CREATE_CLIP Procedure</a> to create the definition table. The following columns are required: <div> <div>COL</div> <div>VARCHAR2 (30)</div> <div>LCUT</div> <div>NUMBER</div> <div>LVAL</div> <div>NUMBER</div> <div>RCUT</div> <div>NUMBER</div> <div>RVAL</div> <div>NUMBER</div> </div> <p>CREATE_CLIP creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_CLIP_TRIM_TAIL.</p> |
| data_table_name | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 49-25 (Cont.) INSERT\_CLIP\_TRIM\_TAIL Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tail_frac</code>        | <p>The percentage of non-null values to be designated as outliers at each end of the data. For example, if <code>tail_frac</code> is .01, then 1% of the data at the low end and 1% of the data at the high end will be treated as outliers.</p> <p>If <code>tail_frac</code> is greater than or equal to .5, no clipping occurs.</p> <p>The default value of <code>tail_frac</code> is 0.025.</p> |
| <code>exclude_list</code>     | <p>List of numerical columns to be excluded from the clipping process. If you do not specify <code>exclude_list</code>, all numerical columns in the data are clipped.</p> <p>The format of <code>exclude_list</code> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                 |
| <code>clip_schema_name</code> | Schema of <code>clip_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                    |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                    |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. The DBMS\_DATA\_MINING\_TRANSFORM package provides two clipping procedures: INSERT\_CLIP\_TRIM\_TAIL and INSERT\_CLIP\_WINSOR\_TAIL. Both procedures compute the boundaries as follows:
  - Count the number of non-null values, *n*, and sort them in ascending order
  - Calculate the number of outliers, *t*, as  $n * tail\_frac$
  - Define the lower boundary *lcut* as the value at position  $1 + floor(t)$
  - Define the upper boundary *rcut* as the value at position  $n - floor(t)$

(The SQL FLOOR function returns the largest integer less than or equal to *t*.)

  - All values that are  $\leq lcut$  or  $\geq rcut$  are designated as outliers.

INSERT\_CLIP\_TRIM\_TAIL replaces the outliers with nulls, effectively removing them from the data.

INSERT\_CLIP\_WINSOR\_TAIL assigns *lcut* to the low outliers and *rcut* to the high outliers.

### Examples

In this example, INSERT\_CLIP\_TRIM\_TAIL trims 10% of the data in two columns (5% from the high end and 5% from the low end) and inserts the transformations in a transformation definition table. The [STACK\\_CLIP Procedure](#) creates a transformation list from the contents of the definition table.

The SQL expression that computes the trimming is shown in the view MINING\_DATA\_STACK. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_credit_limit, cust_city
  FROM sh.customers;
```

```

## 49.6.16 INSERT\_CLIP\_WINSOR\_TAIL Procedure

This procedure replaces numeric outliers with the upper or lower boundary values. It inserts the transformation definitions in a transformation definition table.

`INSERT_CLIP_WINSOR_TAIL` computes the boundaries of the data based on a specified percentage. It replaces the values that fall outside the boundaries (tail values) with the related boundary value. If you wish to set tail values to null, use the [INSERT\\_CLIP\\_TRIM\\_TAIL Procedure](#).

`INSERT_CLIP_WINSOR_TAIL` clips all the `NUMBER` and `FLOAT` columns in the data source unless you specify a list of columns to ignore.

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_CLIP_WINSOR_TAIL (
    clip_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    tail_frac            IN NUMBER DEFAULT 0.025,
    exclude_list         IN COLUMN_LIST DEFAULT NULL,
    clip_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-26 INSERT\_CLIP\_WINSOR\_TAIL Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |

| <code>data_table_name</code>  | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |
| <code>tail_frac</code>        | <p>The percentage of non-null values to be designated as outliers at each end of the data. For example, if <code>tail_frac</code> is .01, then 1% of the data at the low end and 1% of the data at the high end will be treated as outliers.</p> <p>If <code>tail_frac</code> is greater than or equal to .5, no clipping occurs.</p> <p>The default value of <code>tail_frac</code> is 0.025.</p>                                                                                                                                                                                                                                                                                                                                                                   |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |
| <code>exclude_list</code>     | <p>List of numerical columns to be excluded from the clipping process. If you do not specify <code>exclude_list</code>, all numerical columns in the data are clipped.</p> <p>The format of <code>exclude_list</code> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                   |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |
| <code>clip_schema_name</code> | Schema of <code>clip_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |                           |                   |                     |                   |                     |                   |                     |                   |                     |

## Usage Notes

1. See *Oracle Data Mining User's Guide* for details about numerical data.
2. The `DBMS_DATA_MINING_TRANSFORM` package provides two clipping procedures: `INSERT_CLIP_WINSOR_TAIL` and `INSERT_CLIP_TRIM_TAIL`. Both procedures compute the boundaries as follows:

- Count the number of non-null values, *n*, and sort them in ascending order
- Calculate the number of outliers, *t*, as *n\*tail\_frac*
- Define the lower boundary *lcut* as the value at position *1+floor(t)*
- Define the upper boundary *rcut* as the value at position *n-floor(t)*  
(The SQL FLOOR function returns the largest integer less than or equal to *t*.)
- All values that are *<= lcut* or *=> rcut* are designated as outliers.

INSERT\_CLIP\_WINSOR\_TAIL assigns *lcut* to the low outliers and *rcut* to the high outliers.

INSERT\_CLIP\_TRIM\_TAIL replaces the outliers with nulls, effectively removing them from the data.

## Examples

In this example, INSERT\_CLIP\_WINSOR\_TAIL winsorizes 10% of the data in two columns (5% from the high end, and 5% from the low end) and inserts the transformations in a transformation definition table. The STACK\_CLIP Procedure creates a transformation list from the contents of the definition table.

The SQL expression that computes the transformation is shown in the view MINING\_DATA\_STACK. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_credit_limit, cust_city
  FROM sh.customers;
```

describe mining\_data

| Name               | Null?    | Type         |
|--------------------|----------|--------------|
| CUST_ID            | NOT NULL | NUMBER       |
| CUST_YEAR_OF_BIRTH | NOT NULL | NUMBER(4)    |
| CUST_CREDIT_LIMIT  |          | NUMBER       |
| CUST_CITY          | NOT NULL | VARCHAR2(30) |

```
BEGIN
  dbms_data_mining_transform.CREATE_CLIP(
    clip_table_name => 'clip_tbl');
  dbms_data_mining_transform.INSERT_CLIP_WINSOR_TAIL(
    clip_table_name => 'clip_tbl',
    data_table_name => 'mining_data',
    tail_frac       => 0.05,
    exclude_list    => DBMS_DATA_MINING_TRANSFORM.COLUMN_LIST('cust_id'));
END;
```

```
SELECT col, lcut, lval, rcut, rval FROM clip_tbl
  ORDER BY col ASC;

## 49.6.17 INSERT\_MISS\_CAT\_MODE Procedure

This procedure replaces missing categorical values with the value that occurs most frequently in the column (the mode). It inserts the transformation definitions in a transformation definition table.

**INSERT\_MISS\_CAT\_MODE** replaces missing values in all VARCHAR2 and CHAR columns in the data source unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_MISS_CAT_MODE (
    miss_table_name  IN VARCHAR2,
    data_table_name  IN VARCHAR2,
    exclude_list     IN COLUMN_LIST DEFAULT NULL,
    miss_schema_name IN VARCHAR2 DEFAULT NULL,
    data_schema_name IN VARCHAR2 DEFAULT NULL);

```

### Parameters

**Table 49-27 INSERT\_MISS\_CAT\_MODE Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |     |               |     |                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------------|-----|-----------------|
| miss_table_name | <p>Name of the transformation definition table for categorical missing value treatment. You can use the <a href="#">CREATE_MISS_CAT Procedure</a> to create the definition table. The following columns are required:</p> <table> <tr> <td>COL</td><td>VARCHAR2 (30)</td></tr> <tr> <td>VAL</td><td>VARCHAR2 (4000)</td></tr> </table> <p>CREATE_MISS_CAT creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_MISS_CAT_MODE.</p> | COL | VARCHAR2 (30) | VAL | VARCHAR2 (4000) |
| COL             | VARCHAR2 (30)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |     |               |     |                 |
| VAL             | VARCHAR2 (4000)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |               |     |                 |
| data_table_name | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |               |     |                 |

| Parameter                     | Description                                                                                                                                                                                                                                                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exclude_list</code>     | List of categorical columns to be excluded from missing value treatment. If you do not specify <code>exclude_list</code> , all categorical columns are transformed.<br>The format of <code>exclude_list</code> is:<br><br><code>dbms_data_mining_transform.COLUMN_LIST('col1','col2',<br/>... 'coln')</code> |
| <code>miss_schema_name</code> | Schema of <code>miss_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                              |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                              |

### Usage Notes

1. See *Oracle Data Mining User's Guide* for details about categorical data.
2. If you wish to replace categorical missing values with a value other than the mode, you can edit the transformation definition table.

#### See Also:

*Oracle Data Mining User's Guide* for information about default missing value treatment in Oracle Data Mining

### Example

In this example, `INSERT_MISS_CAT_MODE` computes missing value treatment for `cust_city` and inserts the transformation in a transformation definition table. The [STACK\\_MISS\\_CAT Procedure](#) creates a transformation list from the contents of the definition table.

The SQL expression that computes the transformation is shown in the view `MINING_DATA_STACK`. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_year_of_birth, cust_city
    FROM sh.customers;

describe mining_data
Name                                Null?      Type
-----
CUST_ID                            NOT NULL  NUMBER
CUST_YEAR_OF_BIRTH                  NOT NULL  NUMBER(4)
CUST_CITY                           NOT NULL  VARCHAR2(30)

BEGIN
    dbms_data_mining_transform.create_miss_cat(
        miss_table_name => 'missc_tbl');
    dbms_data_mining_transform.insert_miss_cat_mode(
        miss_table_name => 'missc_tbl',
        data_table_name => 'mining_data');
END;
```

```

/

SELECT stats_mode(cust_city) FROM mining_data;

STATS_MODE(CUST_CITY)
-----
Los Angeles

SELECT col, val
       from missc_tbl;

COL                                VAL
-----
CUST_CITY                          Los Angeles

DECLARE
    xforms          dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.STACK_MISS_CAT (
        miss_table_name => 'missc_tbl',
        xform_list      => xforms);
    dbms_data_mining_transform.XFORM_STACK (
        xform_list      => xforms,
        data_table_name => 'mining_data',
        xform_view_name => 'mining_data_stack');
END;
/

set long 3000
SELECT text FROM user_views WHERE view_name IN 'MINING_DATA_STACK';

TEXT
-----
SELECT "CUST_ID","CUST_YEAR_OF_BIRTH",NVL("CUST_CITY",'Los Angeles') "CUST_CITY"
FROM mining_data

```

## 49.6.18 INSERT\_MISS\_NUM\_MEAN Procedure

This procedure replaces missing numerical values with the average (the mean) and inserts the transformation definitions in a transformation definition table.

INSERT\_MISS\_NUM\_MEAN replaces missing values in all NUMBER and FLOAT columns in the data source unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_MISS_NUM_MEAN (
    miss_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    exclude_list         IN COLUMN_LIST DEFAULT NULL,
    round_num            IN PLS_INTEGER DEFAULT 6,
    miss_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-28 INSERT\_MISS\_NUM\_MEAN Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |               |     |        |

```

## 49.6.19 INSERT\_NORM\_LIN\_MINMAX Procedure

This procedure performs linear normalization and inserts the transformation definitions in a transformation definition table.

INSERT\_NORM\_LIN\_MINMAX computes the minimum and maximum values from the data and sets the value of *shift* and *scale* as follows:

```
shift = min
scale = max - min
```

Normalization is computed as:

```
x_new = (x_old - shift) / scale
```

INSERT\_NORM\_LIN\_MINMAX rounds the value of *scale* to a specified number of significant digits before storing it in the transformation definition table.

INSERT\_NORM\_LIN\_MINMAX normalizes all the NUMBER and FLOAT columns in the data source unless you specify a list of columns to ignore.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.INSERT_NORM_LIN_MINMAX (
    norm_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    exclude_list         IN COLUMN_LIST DEFAULT NULL,
    round_num            IN PLS_INTEGER DEFAULT 6,
    norm_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-29** INSERT\_NORM\_LIN\_MINMAX Procedure Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |     |              |       |        |       |        |

| SCALE           | NUMBER                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |              |       |        |       |        |
| data_table_name | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |              |       |        |       |        |
| exclude_list    | <p>List of numerical columns to be excluded from normalization. If you do not specify <i>exclude_list</i>, all numerical columns are transformed.</p> <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>                                                                                                                                                                                                  |     |              |       |        |       |        |
| round_num       | The number of significant digits to use for the minimum and maximum. The default number is 6.                                                                                                                                                                                                                                                                                                                                                                                                                            |     |              |       |        |       |        |

**Table 49-29 (Cont.) INSERT\_NORM\_LIN\_MINMAX Procedure Parameters**

| Parameter        | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| norm_schema_name | Schema of <i>norm_table_name</i> . If no schema is specified, the current schema is used. |
| data_schema_name | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

See *Oracle Data Mining User's Guide* for details about numerical data.

### Examples

In this example, INSERT\_NORM\_LIN\_MINMAX normalizes the *cust\_year\_of\_birth* column and inserts the transformation in a transformation definition table. The [STACK\\_NORM\\_LIN Procedure](#) creates a transformation list from the contents of the definition table.

The SQL expression that computes the transformation is shown in the view MINING\_DATA\_STACK. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_gender, cust_year_of_birth
    FROM sh.customers;
```

```
describe mining_data
```

| Name               | Null?    | Type      |
|--------------------|----------|-----------|
| CUST_ID            | NOT NULL | NUMBER    |
| CUST_GENDER        | NOT NULL | CHAR(1)   |
| CUST_YEAR_OF_BIRTH | NOT NULL | NUMBER(4) |

```
BEGIN
    dbms_data_mining_transform.CREATE_NORM_LIN(
        norm_table_name => 'norm_tbl');
    dbms_data_mining_transform.INSERT_NORM_LIN_MINMAX(
        norm_table_name => 'norm_tbl',
        data_table_name => 'mining_data',
        exclude_list    => dbms_data_mining_transform.COLUMN_LIST( 'cust_id'),
        round_num        => 3);
END;
```

```
/
```

```
SELECT col, shift, scale FROM norm_tbl;
```

| COL                | SHIFT | SCALE |
|--------------------|-------|-------|
| CUST_YEAR_OF_BIRTH | 1910  | 77    |

```
DECLARE
    xforms      dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.STACK_NORM_LIN (
        norm_table_name => 'norm_tbl',
        xform_list       => xforms);
    dbms_data_mining_transform.XFORM_STACK (
        xform_list       => xforms,
```

```

        data_table_name => 'mining_data',
        xform_view_name => 'mining_data_stack');

END;
/

set long 3000
SELECT text FROM user_views WHERE view_name IN 'MINING_DATA_STACK';

TEXT
-----
SELECT "CUST_ID","CUST_GENDER", ("CUST_YEAR_OF_BIRTH"-1910)/77 "CUST_YEAR_OF_BIRT
H" FROM mining_data

```

## 49.6.20 INSERT\_NORM\_LIN\_SCALE Procedure

This procedure performs linear normalization and inserts the transformation definitions in a transformation definition table.

INSERT\_NORM\_LIN\_SCALE computes the minimum and maximum values from the data and sets the value of *shift* and *scale* as follows:

```

shift = 0
scale = max(abs(max), abs(min))

```

Normalization is computed as:

```

x_new = (x_old) / scale

```

INSERT\_NORM\_LIN\_SCALE rounds the value of *scale* to a specified number of significant digits before storing it in the transformation definition table.

INSERT\_NORM\_LIN\_SCALE normalizes all the NUMBER and FLOAT columns in the data source unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_NORM_LIN_SCALE (
    norm_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    exclude_list         IN COLUMN_LIST DEFAULT NULL,
    round_num            IN PLS_INTEGER DEFAULT 6,
    norm_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-30 INSERT\_NORM\_LIN\_SCALE Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |     |              |       |        |       |        |

The default number is 6.                                                                                                                                                                                                                                                                                                                                                                                                                                     |     |              |       |        |       |        |
| norm_schema_name | Schema of <i>norm_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                               |     |              |       |        |       |        |
| data_schema_name | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                               |     |              |       |        |       |        |

## Usage Notes

See *Oracle Data Mining User's Guide* for details about numerical data.

## Examples

In this example, INSERT\_NORM\_LIN\_SCALE normalizes the *cust\_year\_of\_birth* column and inserts the transformation in a transformation definition table. The [STACK\\_NORM\\_LIN Procedure](#) creates a transformation list from the contents of the definition table.

The SQL expression that computes the transformation is shown in the view MINING\_DATA\_STACK. The view is for display purposes only; it cannot be used to embed the transformations in a model.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_gender, cust_year_of_birth
  FROM sh.customers;
```

```
DESCRIBE mining_data
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_GENDER                                NOT NULL CHAR(1)
CUST_YEAR_OF_BIRTH                          NOT NULL NUMBER(4)

BEGIN
  dbms_data_mining_transform.CREATE_NORM_LIN(
```

```

        norm_table_name => 'norm_tbl');
        dbms_data_mining_transform.INSERT_NORM_LIN_SCALE(
        norm_table_name => 'norm_tbl',
        data_table_name => 'mining_data',
        exclude_list    => dbms_data_mining_transform.COLUMN_LIST( 'cust_id'),
        round_num        => 3);
    END;
/

SELECT col, shift, scale FROM norm_tbl;

COL                SHIFT SCALE
-----
CUST_YEAR_OF_BIRTH      0  1990

DECLARE
    xforms            dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.STACK_NORM_LIN (
        norm_table_name => 'norm_tbl',
        xform_list       => xforms);
    dbms_data_mining_transform.XFORM_STACK (
        xform_list       => xforms,
        data_table_name  => 'mining_data',
        xform_view_name  => 'mining_data_stack');
END;
/

set long 3000
SELECT text FROM user_views WHERE view_name IN 'MINING_DATA_STACK';

TEXT

SELECT "CUST_ID","CUST_GENDER",("CUST_YEAR_OF_BIRTH"-0)/1990 "CUST_YEAR_OF_BIRTH
" FROM mining_data

```

## 49.6.21 INSERT\_NORM\_LIN\_ZSCORE Procedure

This procedure performs linear normalization and inserts the transformation definitions in a transformation definition table.

INSERT\_NORM\_LIN\_ZSCORE computes the mean and the standard deviation from the data and sets the value of *shift* and *scale* as follows:

```

shift = mean
scale = stddev

```

Normalization is computed as:

$$x_{new} = (x_{old} - shift) / scale$$

INSERT\_NORM\_LIN\_ZSCORE rounds the value of *scale* to a specified number of significant digits before storing it in the transformation definition table.

INSERT\_NORM\_LIN\_ZSCORE normalizes all the NUMBER and FLOAT columns in the data unless you specify a list of columns to ignore.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.INSERT_NORM_LIN_ZSCORE (
    norm_table_name    IN VARCHAR2,

```

```

data_table_name    IN VARCHAR2,
exclude_list       IN COLUMN_LIST DEFAULT NULL,
round_num          IN PLS_INTEGER DEFAULT 6,
norm_schema_name   IN VARCHAR2 DEFAULT NULL,
data_schema_name   IN VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-31 INSERT\_NORM\_LIN\_ZSCORE Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| norm_table_name  | Name of the transformation definition table for linear normalization. You can use the <a href="#">CREATE_NORM_LIN Procedure</a> to create the definition table. The following columns are required: <div> <div>COL</div> <div>VARCHAR2 (30)</div> <div>SHIFT</div> <div>NUMBER</div> <div>SCALE</div> <div>NUMBER</div> </div> <p>CREATE_NORM_LIN creates an additional column, ATT, which may be used for specifying nested attributes. This column is not used by INSERT_NORM_LIN_ZSCORE.</p> |
| data_table_name  | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| exclude_list     | List of numerical columns to be excluded from normalization. If you do not specify <i>exclude_list</i> , all numerical columns are transformed. <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2', ... 'coln')</pre>                                                                                                                                                                                                                       |
| round_num        | The number of significant digits to use for <i>scale</i> . The default number is 6.                                                                                                                                                                                                                                                                                                                                                                                                             |
| norm_schema_name | Schema of <i>norm_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                       |
| data_schema_name | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                       |

## 49.6.22 SET\_EXPRESSION Procedure

This procedure appends a row to a VARCHAR2 array that stores a SQL expression.

The array can be used for specifying a transformation expression that is too long to be used with the [SET\\_TRANSFORM Procedure](#).

The [GET\\_EXPRESSION Function](#) returns a row in the array.

When you use SET\_EXPRESSION to build a transformation expression, you must build a corresponding reverse transformation expression, create a transformation record, and add the transformation record to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.SET_EXPRESSION (
    expression    IN OUT NOCOPY EXPRESSION_REC,
    chunk        VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-32 SET\_EXPRESSION Procedure Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expression</code> | <p>An expression record (EXPRESSION_REC) that specifies a transformation expression or a reverse transformation expression for an attribute. Each expression record includes a VARCHAR2 array and index fields for specifying upper and lower boundaries within the array.</p> <p>There are two EXPRESSION_REC fields within a transformation record (TRANSFORM_REC): one for the transformation expression; the other for the reverse transformation expression.</p> <p>See <a href="#">Table 49-1</a> for a description of the EXPRESSION_REC type.</p> |
| <code>chunk</code>      | A VARCHAR2 chunk (row) to be appended to <i>expression</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Notes

1. You can pass NULL in the *chunk* argument to SET\_EXPRESSION to clear the previous chunk. The default value of *chunk* is NULL.
2. See ["About Transformation Lists"](#).
3. See ["Operational Notes"](#).

## Examples

In this example, two calls to SET\_EXPRESSION construct a transformation expression and two calls construct the reverse transformation.

### Note:

This example is for illustration purposes only. It shows how SET\_EXPRESSION appends the text provided in *chunk* to the text that already exists in *expression*. The SET\_EXPRESSION procedure is meant for constructing very long transformation expressions that cannot be specified in a VARCHAR2 argument to SET\_TRANSFORM.

Similarly while transformation lists are intended for embedding in a model, the transformation list `v_xlst` is shown in an external view for illustration purposes.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_year_of_birth, cust_postal_code, cust_credit_limit
     FROM sh.customers;

DECLARE
  v_expr dbms_data_mining_transform.EXPRESSION_REC;
  v_rexp dbms_data_mining_transform.EXPRESSION_REC;
  v_xrec dbms_data_mining_transform.TRANSFORM_REC;
  v_xlst dbms_data_mining_transform.TRANSFORM_LIST :=
    dbms_data_mining_transform.TRANSFORM_LIST(NULL);
BEGIN
  dbms_data_mining_transform.SET_EXPRESSION(
    EXPRESSION => v_expr,
    CHUNK      => '("CUST_YEAR_OF_BIRTH"-1910)');
  dbms_data_mining_transform.SET_EXPRESSION(
```

```

        EXPRESSION => v_expr,
        CHUNK      => '/77');
dbms_data_mining_transform.SET_EXPRESSION(
    EXPRESSION => v_rexp,
    CHUNK      => '"CUST_YEAR_OF_BIRTH"*77');
dbms_data_mining_transform.SET_EXPRESSION(
    EXPRESSION => v_rexp,
    CHUNK      => '+1910');

v_xrec := null;
v_xrec.attribute_name := 'CUST_YEAR_OF_BIRTH';
v_xrec.expression := v_expr;
v_xrec.reverse_expression := v_rexp;
v_xlst.TRIM;
v_xlst.extend(1);
v_xlst(1) := v_xrec;

dbms_data_mining_transform.XFORM_STACK (
    xform_list      => v_xlst,
    data_table_name => 'mining_data',
    xform_view_name => 'v_xlst_view');

dbms_output.put_line('====');
FOR i IN 1..v_xlst.count LOOP
    dbms_output.put_line('ATTR: '||v_xlst(i).attribute_name);
    dbms_output.put_line('SUBN: '||v_xlst(i).attribute_subname);
    FOR j IN v_xlst(i).expression.lb..v_xlst(i).expression.ub LOOP
        dbms_output.put_line('EXPR: '||v_xlst(i).expression.lstmt(j));
    END LOOP;
    FOR j IN v_xlst(i).reverse_expression.lb..
        v_xlst(i).reverse_expression.ub LOOP
        dbms_output.put_line('REXP: '||v_xlst(i).reverse_expression.lstmt(j));
    END LOOP;
    dbms_output.put_line('====');
END LOOP;
END;

## 49.6.23 SET\_TRANSFORM Procedure

This procedure appends the transformation instructions for an attribute to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.SET_TRANSFORM (
    xform_list          IN OUT NOCOPY TRANSFORM_LIST,
    attribute_name       VARCHAR2,
    attribute_subname    VARCHAR2,
    expression          VARCHAR2,
    reverse_expression   VARCHAR2,
    attribute_spec       VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-33 SET\_TRANSFORM Procedure Parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xform_list         | A transformation list. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| attribute_name     | Name of the attribute to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| attribute_subname  | Name of the nested attribute if <i>attribute_name</i> is a nested column, otherwise NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| expression         | A SQL expression that specifies the transformation of the attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| reverse_expression | A SQL expression that reverses the transformation for readability in model details and in the target of a supervised model (if the attribute is a target)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| attribute_spec     | <p>One or more keywords that identify special treatment for the attribute during model build. Values are:</p> <ul style="list-style-type: none"> <li>NOPREP — When ADP is on, prevents automatic transformation of the attribute. If ADP is not on, this value has no effect.</li> <li>TEXT — Causes the attribute to be treated as unstructured text data</li> <li>FORCE_IN — Forces the inclusion of the attribute in the model build. Applies only to GLM models with feature selection enabled (<i>ftr_selection_enable</i> = yes). Feature selection is disabled by default.</li> </ul> <p>If the model is not using GLM with feature selection, this value has no effect.</p> <p>See "Specifying Transformation Instructions for an Attribute" in <i>Oracle Data Mining User's Guide</i> for more information about <i>attribute_spec</i>.</p> |

## Usage Notes

- See the following relevant sections in "[Operational Notes](#)":
  - About Transformation Lists
  - Nested Data Transformations
- As shown in the following example, you can eliminate an attribute by specifying a null transformation expression and reverse expression. You can also use the STACK interface to remove a column ([CREATE\\_COL\\_REM Procedure](#) and [STACK\\_COL\\_REM Procedure](#)).

## 49.6.24 STACK\_BIN\_CAT Procedure

This procedure adds categorical binning transformations to a transformation list.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.STACK_BIN_CAT (
    bin_table_name      IN          VARCHAR2,
    xform_list          IN OUT NOCOPY TRANSFORM_LIST,
    literal_flag        IN          BOOLEAN DEFAULT FALSE,
    bin_schema_name     IN          VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-34** STACK\_BIN\_CAT Procedure Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin_table_name</code>  | Name of the transformation definition table for categorical binning. You can use the <a href="#">CREATE_BIN_CAT Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>STACK_BIN_CAT</code> . To populate the table, you can use one of the <code>INSERT</code> procedures for categorical binning or you can write your own SQL.<br>See <a href="#">Table 49-4</a>                                                                                                        |
| <code>xform_list</code>      | A transformation list. See <a href="#">Table 49-1</a> for a description of the <code>TRANSFORM_LIST</code> object type.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>literal_flag</code>    | Indicates whether the values in the <code>bin</code> column in the transformation definition table are valid SQL literals. When <code>literal_flag</code> is <code>FALSE</code> (the default), the bin identifiers will be transformed to SQL literals by surrounding them with single quotes.<br><br>Set <code>literal_flag</code> to <code>TRUE</code> if the bin identifiers are numbers that should have a numeric datatype, as is the case for an O-Cluster model.<br>See " <a href="#">INSERT_BIN_NUM_EQWIDTH Procedure</a> " for an example. |
| <code>bin_schema_name</code> | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Usage Notes

See "[Operational Notes](#)". The following sections are especially relevant:

- "[About Transformation Lists](#)"
- "[About Stacking](#)"
- "[Nested Data Transformations](#)"

## Examples

This example shows how a binning transformation for the categorical column `cust_postal_code` could be added to a stack called `mining_data_stack`.

### Note:

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. `XFORM_STACK` simply generates an external view of the transformed data. The actual purpose of the `STACK` procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to `CREATE_MODEL` in the `xform_list` parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

```
CREATE or REPLACE VIEW mining_data AS
  SELECT cust_id, cust_postal_code, cust_credit_limit
  FROM sh.customers
  WHERE cust_id BETWEEN 100050 AND 100100;
BEGIN
  dbms_data_mining_transform.CREATE_BIN_CAT ('bin_cat_tbl');
```

```

    dbms_data_mining_transform.INSERT_BIN_CAT_FREQ (
        bin_table_name => 'bin_cat_tbl',
        data_table_name => 'mining_data',
        bin_num         => 3);
END;
/
DECLARE
    MINING_DATA_STACK dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
    dbms_data_mining_transform.STACK_BIN_CAT (
        bin_table_name => 'bin_cat_tbl',
        xform_list      => mining_data_stack);
    dbms_data_mining_transform.XFORM_STACK (
        xform_list      => mining_data_stack,
        data_table_name => 'mining_data',
        xform_view_name => 'mining_data_stack_view');
END;
/
-- Before transformation
column cust_postal_code format a16
SELECT * from mining_data
        WHERE cust_id BETWEEN 100050 AND 100053
        ORDER BY cust_id;

CUST_ID CUST_POSTAL_CODE CUST_CREDIT_LIMIT
-----
100050 76486                1500
100051 73216                9000
100052 69499                5000
100053 45704                7000

-- After transformation
SELECT * FROM mining_data_stack_view
        WHERE cust_id BETWEEN 100050 AND 100053
        ORDER BY cust_id;

CUST_ID CUST_POSTAL_CODE CUST_CREDIT_LIMIT
-----
100050 4                    1500
100051 1                    9000
100052 4                    5000
100053 4                    7000

```

## 49.6.25 STACK\_BIN\_NUM Procedure

This procedure adds numerical binning transformations to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.STACK_BIN_NUM (
    bin_table_name    IN          VARCHAR2,
    xform_list        IN OUT      NOCOPY TRANSFORM_LIST,
    literal_flag       IN          BOOLEAN DEFAULT FALSE,
    bin_schema_name    IN          VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-35** STACK\_BIN\_NUM Procedure Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin_table_name</code>  | Name of the transformation definition table for numerical binning. You can use the <a href="#">CREATE_BIN_NUM Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>STACK_BIN_NUM</code> . To populate the table, you can use one of the <code>INSERT</code> procedures for numerical binning or you can write your own SQL. See <a href="#">Table 49-6</a> .                                                                                                                 |
| <code>xform_list</code>      | A transformation list. See <a href="#">Table 49-1</a> for a description of the <code>TRANSFORM_LIST</code> object type.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>literal_flag</code>    | Indicates whether the values in the <code>bin</code> column in the transformation definition table are valid SQL literals. ## 49.6.26 STACK\_CLIP Procedure

This procedure adds clipping transformations to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.STACK_CLIP (
  clip_table_name  IN          VARCHAR2,
  xform_list       IN OUT NOCOPY TRANSFORM_LIST,
  clip_schema_name IN          VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-36** STACK\_CLIP Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                        |

- “About Transformation Lists”
- “About Stacking”
- “Nested Data Transformations”

## Examples

This example shows how a clipping transformation for the numerical column `cust_credit_limit` could be added to a stack called `mining_data_stack`.

### Note:

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. XFORM\_STACK simply generates an external view of the transformed data. The actual purpose of the STACK procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to CREATE\_MODEL in the xform\_list parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, cust_postal_code, cust_credit_limit
  FROM sh.customers
  WHERE cust_id BETWEEN 100050 AND 100100;
BEGIN
  dbms_data_mining_transform.create_clip ('clip_tbl');
  dbms_data_mining_transform.insert_clip_winsor_tail (
    clip_table_name => 'clip_tbl',
    data_table_name => 'mining_data',
    tail_frac       => 0.25,
    exclude_list    => dbms_data_mining_transform.COLUMN_LIST('cust_id'));
END;
/
```

```

DECLARE
  MINING_DATA_STACK  dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
  dbms_data_mining_transform.STACK_CLIP (
    clip_table_name    => 'clip_tbl',
    xform_list         => mining_data_stack);
  dbms_data_mining_transform.XFORM_STACK (
    xform_list         => mining_data_stack,
    data_table_name    => 'mining_data',
    xform_view_name    => 'mining_data_stack_view');

```

```
END;
```

```
/
```

```
-- Before transformation
```

```

SELECT cust_id, cust_postal_code, round(cust_credit_limit)
FROM mining_data
WHERE cust_id BETWEEN 100050 AND 100054
ORDER BY cust_id;

```

## 49.6.27 STACK\_COL\_REM Procedure

This procedure adds column removal transformations to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.STACK_COL_REM (
  rem_table_name      IN          VARCHAR2,
  xform_list          IN OUT NOCOPY TRANSFORM_LIST,
  rem_schema_name     IN          VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-37 STACK\_COL\_REM Procedure Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rem_table_name  | Name of the transformation definition table for column removal. You can use the <a href="#">CREATE_COL_REM Procedure</a> to create the definition table. See <a href="#">Table 49-10</a> .<br>The table must be populated with column names before you call STACK_COL_REM. The <a href="#">INSERT_BIN_SUPER Procedure</a> and the <a href="#">INSERT_AUTOBIN_NUM_EQWIDTH Procedure</a> can optionally be used to populate the table. You can also use SQL INSERT statements. |
| xform_list      | A transformation list. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type.                                                                                                                                                                                                                                                                                                                                                                   |
| rem_schema_name | Schema of rem_table_name. If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                             |

## Usage Notes

See "Operational Notes". The following sections are especially relevant:

- ["About Transformation Lists"](#)
- ["About Stacking"](#)
- ["Nested Data Transformations"](#)

## Examples

This example shows how the column cust\_credit\_limit could be removed in a transformation list called mining\_data\_stack.

### Note:

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. XFORM\_STACK simply generates an external view of the transformed data. The actual purpose of the STACK procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to CREATE\_MODEL in the xform\_list parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, country_id, cust_postal_code, cust_credit_limit
     FROM sh.customers;

BEGIN
  dbms_data_mining_transform.create_col_rem ('rem_tbl');
END;
/

INSERT into rem_tbl VALUES (upper('cust_postal_code'), null);

DECLARE
  MINING_DATA_STACK  dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
```

```

dbms_data_mining_transform.stack_col_rem (
    rem_table_name      => 'rem_tbl',
    xform_list          => mining_data_stack);
dbms_data_mining_transform.XFORM_STACK (
    xform_list          => mining_data_stack,
    data_table_name     => 'mining_data',
    xform_view_name     => 'mining_data_stack_view');
END;
/

SELECT * FROM mining_data
WHERE cust_id BETWEEN 100050 AND 100051
ORDER BY cust_id;

CUST_ID    COUNTRY_ID    CUST_POSTAL_CODE    CUST_CREDIT_LIMIT
-----
100050      52773      76486                1500
100051      52790      73216                9000

SELECT * FROM mining_data_stack_view
WHERE cust_id BETWEEN 100050 AND 100051
ORDER BY cust_id;

CUST_ID    COUNTRY_ID    CUST_CREDIT_LIMIT
-----
100050      52773                1500
100051      52790                9000

```

## 49.6.28 STACK\_MISS\_CAT Procedure

This procedure adds categorical missing value transformations to a transformation list.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.STACK_MISS_CAT (
    miss_table_name     IN      VARCHAR2,
    xform_list          IN OUT  NOCOPY TRANSFORM_LIST,
    miss_schema_name    IN      VARCHAR2 DEFAULT NULL);

```

### Parameters

**Table 49-38 STACK\_MISS\_CAT Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| miss_table_name  | Name of the transformation definition table for categorical missing value treatment. You can use the <a href="#">CREATE_MISS_CAT Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call STACK_MISS_CAT. To populate the table, you can use the <a href="#">INSERT_MISS_CAT_MODE Procedure</a> or you can write your own SQL. See <a href="#">Table 49-12</a> . |
| xform_list       | A transformation list. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type.                                                                                                                                                                                                                                                                                                                        |
| miss_schema_name | Schema of miss_table_name. If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                 |

### Usage Notes

See "[Operational Notes](#)". The following sections are especially relevant:

- ["About Transformation Lists"](#)
- ["About Stacking"](#)
- ["Nested Data Transformations"](#)

## Examples

This example shows how the missing values in the column `cust_marital_status` could be replaced with the mode in a transformation list called `mining_data_stack`.

### Note:

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. `XFORM_STACK` simply generates an external view of the transformed data. The actual purpose of the `STACK` procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to `CREATE_MODEL` in the `xform_list` parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

```
CREATE OR REPLACE VIEW mining_data AS
  SELECT cust_id, country_id, cust_marital_status
     FROM sh.customers
    where cust_id BETWEEN 1 AND 10;

BEGIN
  dbms_data_mining_transform.create_miss_cat ('miss_cat_tbl');
  dbms_data_mining_transform.insert_miss_cat_mode ('miss_cat_tbl', 'mining_data');
END;
/

DECLARE
  MINING_DATA_STACK  dbms_data_mining_transform.TRANSFORM_LIST;
BEGIN
  dbms_data_mining_transform.stack_miss_cat (
    miss_table_name => 'miss_cat_tbl',
    xform_list      => mining_data_stack);
  dbms_data_mining_transform.XFORM_STACK (
    xform_list      => mining_data_stack,
    data_table_name => 'mining_data',
    xform_view_name => 'mining_data_stack_view');
END;
/
SELECT * FROM mining_data
  ORDER BY cust_id;
```

| CUST_ID | COUNTRY_ID | CUST_MARITAL_STATUS |
|---------|------------|---------------------|
| 1       | 52789      |                     |

| 8       | 52790      | married             |
| 9       | 52770      | divorced            |
| 10      | 52790      | widow               |

## 49.6.29 STACK\_MISS\_NUM Procedure

This procedure adds numeric missing value transformations to a transformation list.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.STACK_MISS_NUM (
    miss_table_name    IN      VARCHAR2,
    xform_list         IN OUT  NOCOPY TRANSFORM_LIST,
    miss_schema_name   IN      VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-39** STACK\_MISS\_NUM Procedure Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| miss_table_name  | Name of the transformation definition table for numerical missing value treatment. You can use the <a href="#">CREATE_MISS_NUM Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call STACK_MISS_NUM. To populate the table, you can use the <a href="#">INSERT_MISS_NUM_MEAN Procedure</a> or you can write your own SQL. See <a href="#">Table 49-14</a> . |
| xform_list       | A transformation list. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type.                                                                                                                                                                                                                                                                                                                      |
| miss_schema_name | Schema of <i>miss_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                       |

### Usage Notes

See "Operational Notes". The following sections are especially relevant:

- ["About Transformation Lists"](#)
- ["About Stacking"](#)
- ["Nested Data Transformations"](#)

### Examples

This example shows how the missing values in the column `cust_credit_limit` could be replaced with the mean in a transformation list called `mining_data_stack`.

#### Note:

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. `XFORM_STACK` simply generates an external view of the transformed data. The actual purpose of the `STACK` procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to `CREATE_MODEL` in the `xform_list` parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

## 49.6.30 STACK\_NORM\_LIN Procedure

This procedure adds linear normalization transformations to a transformation list.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.STACK_NORM_LIN (
    norm_table_name      IN      VARCHAR2,
    xform_list           IN OUT  NOCOPY TRANSFORM_LIST,
    norm_schema_name     IN      VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 49-40 STACK\_NORM\_LIN Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>norm_table_name</code>  | Name of the transformation definition table for linear normalization. You can use the <a href="#">CREATE_NORM_LIN Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>STACK_NORM_LIN</code> . To populate the table, you can use one of the <code>INSERT</code> procedures for normalization or you can write your own SQL. See <a href="#">Table 49-16</a> . |
| <code>xform_list</code>       | A transformation list. See <a href="#">Table 49-1</a> for a description of the <code>TRANSFORM_LIST</code> object type.                                                                                                                                                                                                                                                                                                                   |
| <code>norm_schema_name</code> | Schema of <code>norm_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                           |

### Usage Notes

See "Operational Notes". The following sections are especially relevant:

- ["About Transformation Lists"](#)
- ["About Stacking"](#)
- ["Nested Data Transformations"](#)

### Examples

This example shows how the column `cust_credit_limit` could be normalized in a transformation list called `mining_data_stack`.

**Note:**

This example invokes the [XFORM\\_STACK Procedure](#) to show how the data is transformed by the stack. `XFORM_STACK` simply generates an external view of the transformed data. The actual purpose of the `STACK` procedures is to assemble a list of transformations for embedding in a model. The transformations are passed to `CREATE_MODEL` in the `xform_list` parameter. See [INSERT\\_BIN\\_NUM\\_EQWIDTH Procedure](#) for an example.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, country_id, cust_postal_code, cust_credit_limit
    FROM sh.customers;

BEGIN
    dbms_data_mining_transform.create_norm_lin ('norm_lin_tbl');
    dbms_data_mining_transform.insert_norm_lin_minmax (
        norm_table_name => 'norm_lin_tbl',
        data_table_name => 'mining_data',
        exclude_list    => dbms_data_mining_transform.COLUMN_LIST('cust_id',
                                                                    'country_id'));
END;
/
SELECT * FROM norm_lin_tbl;
COL          ATT      SHIFT  SCALE
-----
CUST_CREDIT_LIMIT          1500  13500

### 49.6.31 XFORM\_BIN\_CAT Procedure

This procedure creates a view that implements the categorical binning transformations specified in a definition table. Only the columns that are specified in the definition table are transformed; the remaining columns from the data table are present in the view, but they are not changed.

#### Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_BIN_CAT (
    bin_table_name      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    xform_view_name     IN VARCHAR2,
    literal_flag        IN BOOLEAN DEFAULT FALSE,
    bin_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL,
    xform_schema_name   IN VARCHAR2 DEFAULT NULL);
```

#### Parameters

**Table 49-41 XFORM\_BIN\_CAT Procedure Parameters**

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin_table_name</code>   | Name of the transformation definition table for categorical binning. You can use the <a href="#">CREATE_BIN_CAT Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>XFORM_BIN_CAT</code> . To populate the table, you can use one of the <code>INSERT</code> procedures for categorical binning or you can write your own SQL. See <a href="#">Table 49-4</a> .                                                                                                      |
| <code>data_table_name</code>  | Name of the table containing the data to be transformed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>xform_view_name</code>  | Name of the view to be created. The view presents columns in <code>data_table_name</code> with the transformations specified in <code>bin_table_name</code> .                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>literal_flag</code>     | Indicates whether the values in the <code>bin</code> column in the transformation definition table are valid SQL literals. When <code>literal_flag</code> is <code>FALSE</code> (the default), the bin identifiers will be transformed to SQL literals by surrounding them with single quotes.<br><br>Set <code>literal_flag</code> to <code>TRUE</code> if the bin identifiers are numbers that should have a numeric datatype, as is the case for an O-Cluster model. See " <a href="#">INSERT_BIN_NUM_EQWIDTH Procedure</a> " for an example. |
| <code>bin_schema_name</code>  | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>data_schema_name</code> | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 49-41 (Cont.) XFORM\_BIN\_CAT Procedure Parameters**

| Parameter         | Description                                                                               |
|-------------------|-------------------------------------------------------------------------------------------|
| xform_schema_name | Schema of <i>xform_view_name</i> . If no schema is specified, the current schema is used. |

### Usage Notes

See ["Operational Notes"](#).

### Examples

This example creates a view that bins the *cust\_postal\_code* column. The data source consists of three columns from *sh.customer*.

```
describe mining_data

## 49.6.32 XFORM\_BIN\_NUM Procedure

This procedure creates a view that implements the numerical binning transformations specified in a definition table. Only the columns that are specified in the definition table are transformed; the remaining columns from the data table are present in the view, but they are not changed.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.XFORM_BIN_NUM (
    bin_table_name      IN VARCHAR2,
    data_table_name     IN VARCHAR2,
    xform_view_name     IN VARCHAR2,
    literal_flag        IN BOOLEAN DEFAULT FALSE,
    bin_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name    IN VARCHAR2 DEFAULT NULL,
    xform_schema_name   IN VARCHAR2 DEFAULT NULL);

```

### Parameters

**Table 49-42 XFORM\_BIN\_NUM Procedure Parameters**

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin_table_name</code>  | Name of the transformation definition table for numerical binning. You can use the <a href="#">CREATE_BIN_NUM Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>XFORM_BIN_NUM</code> . To populate the table, you can use one of the <code>INSERT</code> procedures for numerical binning or you can write your own SQL. See " <a href="#">Table 49-6</a> ". |
| <code>data_table_name</code> | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>xform_view_name</code> | Name of the view to be created. The view presents columns in <code>data_table_name</code> with the transformations specified in <code>bin_table_name</code> .                                                                                                                                                                                                                                                                              |

**Table 49-42 (Cont.) XFORM\_BIN\_NUM Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>literal_flag</code>      | Indicates whether the values in the <code>bin</code> column in the transformation definition table are valid SQL literals. When <code>literal_flag</code> is <code>FALSE</code> (the default), the bin identifiers will be transformed to SQL literals by surrounding them with single quotes.<br><br>Set <code>literal_flag</code> to <code>TRUE</code> if the bin identifiers are numbers that should have a numeric datatype, as is the case for an O-Cluster model.<br><br>See " <a href="#">INSERT_BIN_NUM_EQWIDTH Procedure</a> " for an example. |
| <code>bin_schema_name</code>   | Schema of <code>bin_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>data_schema_name</code>  | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>xform_schema_name</code> | Schema of <code>xform_view_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Usage Notes

See "[Operational Notes](#)".

### Examples

This example creates a view that bins the `cust_credit_limit` column. The data source consists of three columns from `sh.customer`.

```
describe mining_data
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_POSTAL_CODE                           NOT NULL VARCHAR2(10)
CUST_CREDIT_LIMIT                           NUMBER

column cust_credit_limit off
SELECT * FROM mining_data WHERE cust_id between 104066 and 104069;

      CUST_ID CUST_POSTAL_CODE  CUST_CREDIT_LIMIT

```

### 49.6.33 XFORM\_CLIP Procedure

This procedure creates a view that implements the clipping transformations specified in a definition table. Only the columns that are specified in the definition table are transformed; the remaining columns from the data table are present in the view, but they are not changed.

#### Syntax

```

DBMS_DATA_MINING_TRANSFORM.XFORM_CLIP (
  clip_table_name      IN VARCHAR2,
  data_table_name       IN VARCHAR2,
  xform_view_name      IN VARCHAR2,
  clip_schema_name     IN VARCHAR2 DEFAULT NULL,

```

```

data_schema_name      IN VARCHAR2,DEFAULT NULL,
xform_schema_name     IN VARCHAR2,DEFAULT NULL);

```

## Parameters

**Table 49-43 XFORM\_CLIP Procedure Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clip_table_name   | Name of the transformation definition table for clipping. You can use the <a href="#">CREATE_CLIP Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call XFORM_CLIP. To populate the table, you can use one of the INSERT procedures for clipping you can write your own SQL.<br>See <a href="#">Table 49-8</a> . |
| data_table_name   | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                              |
| xform_view_name   | Name of the view to be created. The view presents columns in <i>data_table_name</i> with the transformations specified in <i>clip_table_name</i> .                                                                                                                                                                                                                                   |
| clip_schema_name  | Schema of <i>clip_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                            |
| data_schema_name  | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                            |
| xform_schema_name | Schema of <i>xform_view_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                            |

## Examples

This example creates a view that clips the *cust\_credit\_limit* column. The data source consists of three columns from *sh.customer*.

```

describe mining_data
Name                               Null?    Type
-----
CUST_ID                           NOT NULL NUMBER
CUST_POSTAL_CODE                  NOT NULL VARCHAR2(10)
CUST_CREDIT_LIMIT                  NUMBER

BEGIN
  dbms_data_mining_transform.create_clip(
    clip_table_name => 'clip_tbl');
  dbms_data_mining_transform.insert_clip_trim_tail(
    clip_table_name => 'clip_tbl',
    data_table_name => 'mining_data',
    tail_frac       => 0.05,
    exclude_list    => dbms_data_mining_transform.COLUMN_LIST('cust_id'));
  dbms_data_mining_transform.xform_clip(
    clip_table_name => 'clip_tbl',
    data_table_name => 'mining_data',
    xform_view_name => 'clip_view');
END;
/
describe clip_view
Name                               Null?    Type
-----
CUST_ID                           NOT NULL NUMBER
CUST_POSTAL_CODE                  NOT NULL VARCHAR2(10)
CUST_CREDIT_LIMIT                  NUMBER

```

```

SELECT MIN(cust_credit_limit), MAX(cust_credit_limit) FROM mining_data;

MIN(CUST_CREDIT_LIMIT) MAX(CUST_CREDIT_LIMIT)
-----
1500                      15000

SELECT MIN(cust_credit_limit), MAX(cust_credit_limit) FROM clip_view;

MIN(CUST_CREDIT_LIMIT) MAX(CUST_CREDIT_LIMIT)
-----
1500                      11000

set long 2000
SELECT text FROM user_views WHERE view_name IN 'CLIP_VIEW';

TEXT
-----
SELECT "CUST_ID","CUST_POSTAL_CODE",CASE WHEN "CUST_CREDIT_LIMIT" < 1500 THEN NU
LL WHEN "CUST_CREDIT_LIMIT" > 11000 THEN NULL ELSE "CUST_CREDIT_LIMIT" END "CUST
_CREDIT_LIMIT" FROM mining_data

```

### 49.6.34 XFORM\_COL\_REM Procedure

This procedure creates a view that implements the column removal transformations specified in a definition table. Only the columns that are specified in the definition table are removed; the remaining columns from the data table are present in the view.

#### Syntax

```

DBMS_DATA_MINING_TRANSFORM.XFORM_COL_REM (
    rem_table_name      IN      VARCHAR2,
    data_table_name     IN      VARCHAR2,
    xform_view_name     IN      VARCHAR2,
    rem_schema_name     IN      VARCHAR2 DEFAULT NULL,
    data_schema_name    IN      VARCHAR2 DEFAULT NULL,
    xform_schema_name   IN      VARCHAR2 DEFAULT NULL);

```

#### Parameters

**Table 49-44 XFORM\_COL\_REM Procedure Parameters**

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rem_table_name   | Name of the transformation definition table for column removal. You can use the <a href="#">CREATE_COL_REM Procedure</a> to create the definition table. See <a href="#">Table 49-10</a> .<br><br>The table must be populated with column names before you call XFORM_COL_REM. The <a href="#">INSERT_BIN_SUPER Procedure</a> and the <a href="#">INSERT_AUTOBIN_NUM_EQWIDTH Procedure</a> can optionally be used to populate the table. You can also use SQL INSERT statements. |
| data_table_name  | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                                                          |
| xform_view_name  | Name of the view to be created. The view presents the columns in <i>data_table_name</i> that are not specified in <i>rem_table_name</i> .                                                                                                                                                                                                                                                                                                                                        |
| rem_schema_name  | Schema of <i>rem_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                         |
| data_schema_name | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 49-44 (Cont.) XFORM\_COL\_REM Procedure Parameters**

| Parameter                      | Description                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------|
| <code>xform_schema_name</code> | Schema of <code>xform_view_name</code> . If no schema is specified, the current schema is used. |

### Usage Notes

See ["Operational Notes"](#).

### Examples

This example creates a view that includes all but one column from the table `customers` in the current schema.

```
describe customers
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_MARITAL_STATUS                        VARCHA2 (20)
OCCUPATION                                VARCHA2 (21)
AGE                                         NUMBER
YRS_RESIDENCE                             NUMBER

BEGIN
  DBMS_DATA_MINING_TRANSFORM.CREATE_COL_REM ('colrem_xtbl');
END;
/
INSERT INTO colrem_xtbl VALUES('CUST_MARITAL_STATUS', null);

NOTE: This currently doesn't work. See bug 9310319

BEGIN
  DBMS_DATA_MINING_TRANSFORM.XFORM_COL_REM (
    rem_table_name      => 'colrem_xtbl',
    data_table_name     => 'customers',
    xform_view_name     => 'colrem_view');
END;
/
describe colrem_view

Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
OCCUPATION                                VARCHA2 (21)
AGE                                         NUMBER
YRS_RESIDENCE                             NUMBER
```

## 49.6.35 XFORM\_EXPR\_NUM Procedure

This procedure creates a view that implements the specified numeric transformations. Only the columns that you specify are transformed; the remaining columns from the data table are present in the view, but they are not changed.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_EXPR_NUM (
  expr_pattern      IN      VARCHAR2,
```

```

data_table_name    IN      VARCHAR2,
xform_view_name    IN      VARCHAR2,
exclude_list       IN      COLUMN_LIST DEFAULT NULL,
include_list       IN      COLUMN_LIST DEFAULT NULL,
col_pattern        IN      VARCHAR2 DEFAULT ':col',
data_schema_name   IN      VARCHAR2 DEFAULT NULL,
xform_schema_name  IN      VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-45 XFORM\_EXPR\_NUM Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr_pattern</code>      | A numeric transformation expression                                                                                                                                                                                                                        |
| <code>data_table_name</code>   | Name of the table containing the data to be transformed                                                                                                                                                                                                    |
| <code>xform_view_name</code>   | Name of the view to be created. The view presents columns in <i>data_table_name</i> with the transformations specified in <i>expr_pattern</i> and <i>col_pattern</i> .                                                                                     |
| <code>exclude_list</code>      | <p>List of numerical columns to exclude. If NULL, no numerical columns are excluded.</p> <p>The format of <i>exclude_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre> |
| <code>include_list</code>      | <p>List of numeric columns to include. If NULL, all numeric columns are included.</p> <p>The format of <i>include_list</i> is:</p> <pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>    |
| <code>col_pattern</code>       | <p>The value within <i>expr_pattern</i> that will be replaced with a column name. The value of <i>col_pattern</i> is case-sensitive.</p> <p>The default value of <i>col_pattern</i> is <code>:col</code></p>                                               |
| <code>data_schema_name</code>  | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                  |
| <code>xform_schema_name</code> | Schema of <i>xform_view_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                  |

## Usage Notes

1. The `XFORM_EXPR_NUM` procedure constructs numeric transformation expressions from the specified expression pattern (*expr\_pattern*) by replacing every occurrence of the specified column pattern (*col\_pattern*) with an actual column name.

`XFORM_EXPR_NUM` uses the SQL `REPLACE` function to construct the transformation expressions.

```
REPLACE (expr_pattern,col_pattern,'"column_name"' ) || '"column_name'"
```

If there is a column match, then the replacement is made in the transformation expression; if there is not a match, then the column is used without transformation.

**See:**  
*Oracle Database SQL Language Reference* for information about the `REPLACE` function

2. Because of the include and exclude list parameters, the `XFORM_EXPR_NUM` and `XFORM_EXPR_STR` procedures allow you to easily specify individual columns for transformation within large data sets. The other `XFORM_*` procedures support an exclude list only. In these procedures, you must enumerate every column that you do not want to transform.
3. See "[Operational Notes](#)"

### Examples

This example creates a view that transforms the datatype of numeric columns.

```
describe customers
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_MARITAL_STATUS                        VARCHAR2(20)
OCCUPATION                                 VARCHAR2(21)
AGE                                         NUMBER
YRS_RESIDENCE                             NUMBER

BEGIN
  DBMS_DATA_MINING_TRANSFORM.XFORM_EXPR_NUM(
    expr_pattern      => 'to_char(:col)',
    data_table_name   => 'customers',
    xform_view_name    => 'cust_nonum_view',
    exclude_list      => dbms_data_mining_transform.COLUMN_LIST( 'cust_id'),
    include_list       => null,
    col_pattern        => ':col');
END;
/
describe cust_nonum_view
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_MARITAL_STATUS                        VARCHAR2(20)
OCCUPATION                                 VARCHAR2(21)
AGE                                         VARCHAR2(40)
YRS_RESIDENCE                             VARCHAR2(40)
```

## 49.6.36 XFORM\_EXPR\_STR Procedure

This procedure creates a view that implements the specified categorical transformations. Only the columns that you specify are transformed; the remaining columns from the data table are present in the view, but they are not changed.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_EXPR_STR (
  expr_pattern      IN      VARCHAR2,
  data_table_name   IN      VARCHAR2,
  xform_view_name    IN      VARCHAR2,
  exclude_list      IN      COLUMN_LIST DEFAULT NULL,
  include_list       IN      COLUMN_LIST DEFAULT NULL,
```

```

col_pattern      IN      VARCHAR2 DEFAULT ':col',
data_schema_name IN      VARCHAR2 DEFAULT NULL,
xform_schema_name IN     VARCHAR2 DEFAULT NULL);

```

## Parameters

**Table 49-46 XFORM\_EXPR\_STR Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expr_pattern</code>      | A character transformation expression                                                                                                                                                                                                                      |
| <code>data_table_name</code>   | Name of the table containing the data to be transformed                                                                                                                                                                                                    |
| <code>xform_view_name</code>   | Name of the view to be created. The view presents columns in <i>data_table_name</i> with the transformations specified in <i>expr_pattern</i> and <i>col_pattern</i> .                                                                                     |
| <code>exclude_list</code>      | List of categorical columns to exclude. If NULL, no categorical columns are excluded.<br>The format of <i>exclude_list</i> is:<br><br><pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre> |
| <code>include_list</code>      | List of character columns to include. If NULL, all character columns are included.<br>The format of <i>include_list</i> is:<br><br><pre>dbms_data_mining_transform.COLUMN_LIST('col1','col2',                                          ...'coln')</pre>    |
| <code>col_pattern</code>       | The value within <i>expr_pattern</i> that will be replaced with a column name. The value of <i>col_pattern</i> is case-sensitive.<br>The default value of <i>col_pattern</i> is <code>:col</code>                                                          |
| <code>data_schema_name</code>  | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                  |
| <code>xform_schema_name</code> | Schema of <i>xform_view_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                  |

## Usage Notes

1. The `XFORM_EXPR_STR` procedure constructs character transformation expressions from the specified expression pattern (*expr\_pattern*) by replacing every occurrence of the specified column pattern (*col\_pattern*) with an actual column name.

`XFORM_EXPR_STR` uses the SQL `REPLACE` function to construct the transformation expressions.

```
REPLACE (expr_pattern,col_pattern,'"column_name"' ) || '"column_name'"
```

If there is a column match, then the replacement is made in the transformation expression; if there is not a match, then the column is used without transformation.

**See:**  
*Oracle Database SQL Language Reference* for information about the `REPLACE` function

2. Because of the include and exclude list parameters, the `XFORM_EXPR_STR` and `XFORM_EXPR_NUM` procedures allow you to easily specify individual columns for transformation within large data sets. The other `XFORM_*` procedures support an exclude list only. In these procedures, you must enumerate every column that you do not want to transform.
3. See "[Operational Notes](#)"

### Examples

This example creates a view that transforms character columns to upper case.

```
describe customers
Name                                         Null?    Type
-----
CUST_ID                                     NOT NULL NUMBER
CUST_MARITAL_STATUS                        VARCHAR2(20)
OCCUPATION                                 VARCHAR2(21)
AGE                                         NUMBER
YRS_RESIDENCE                             NUMBER

SELECT cust_id, cust_marital_status, occupation FROM customers
       WHERE cust_id > 102995
       ORDER BY cust_id desc;

## 49.6.37 XFORM\_MISS\_CAT Procedure

This procedure creates a view that implements the categorical missing value treatment transformations specified in a definition table. Only the columns that are specified in the definition table are transformed; the remaining columns from the data table are present in the view, but they are not changed.

### Syntax

```

DBMS_DATA_MINING_TRANSFORM.XFORM_MISS_CAT (
    miss_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    xform_view_name      IN VARCHAR2,
    miss_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL,
    xform_schema_name    IN VARCHAR2 DEFAULT NULL;

```

### Parameters

**Table 49-47 XFORM\_MISS\_CAT Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>miss_table_name</code>   | Name of the transformation definition table for categorical missing value treatment. You can use the <a href="#">CREATE_MISS_CAT Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>XFORM_MISS_CAT</code> . To populate the table, you can use the <a href="#">INSERT_MISS_CAT_MODE Procedure</a> or you can write your own SQL. See <a href="#">Table 49-12</a> . |
| <code>data_table_name</code>   | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>xform_view_name</code>   | Name of the view to be created. The view presents columns in <code>data_table_name</code> with the transformations specified in <code>miss_table_name</code> .                                                                                                                                                                                                                                                                                  |
| <code>miss_schema_name</code>  | Schema of <code>miss_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                 |
| <code>data_schema_name</code>  | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                 |
| <code>xform_schema_name</code> | Schema of <code>xform_view_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                                 |

### Usage Notes

See ["Operational Notes"](#).

### Examples

This example creates a view that replaces missing categorical values with the mode.

## 49.6.38 XFORM\_MISS\_NUM Procedure

This procedure creates a view that implements the numerical missing value treatment transformations specified in a definition table. Only the columns that are specified in the definition table are transformed; the remaining columns from the data table are present in the view, but they are not changed.

### Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_MISS_NUM (
    miss_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    xform_view_name      IN VARCHAR2,
    miss_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL,
    xform_schema_name    IN VARCHAR2 DEFAULT NULL;
```

### Parameters

**Table 49-48 XFORM\_MISS\_NUM Procedure Parameters**

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>miss_table_name</code>   | Name of the transformation definition table for numerical missing value treatment. You can use the <a href="#">CREATE_MISS_NUM Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call <code>XFORM_MISS_NUM</code> . To populate the table, you can use the <a href="#">INSERT_MISS_NUM_MEAN Procedure</a> or you can write your own SQL. See <a href="#">Table 49-14</a> . |
| <code>data_table_name</code>   | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>xform_view_name</code>   | Name of the view to be created. The view presents columns in <code>data_table_name</code> with the transformations specified in <code>miss_table_name</code> .                                                                                                                                                                                                                                                                                |
| <code>miss_schema_name</code>  | Schema of <code>miss_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                               |
| <code>data_schema_name</code>  | Schema of <code>data_table_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                               |
| <code>xform_schema_name</code> | Schema of <code>xform_view_name</code> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                                               |

### Usage Notes

See "[Operational Notes](#)".

### Examples

This example creates a view that replaces missing numerical values with the mean.

```
SELECT * FROM items;

ITEM_ID      QTY
-----
aa           200
```

```

bb          200
cc          250
dd
ee
ff          100
gg          250
hh          200
ii
jj          200

SELECT AVG(qty) FROM items;

AVG(QTY)
-----
      200

BEGIN
  DBMS_DATA_MINING_TRANSFORM.CREATE_MISS_NUM('misssum_xtbl');
  DBMS_DATA_MINING_TRANSFORM.INSERT_MISS_NUM_MEAN (
    miss_table_name      => 'misssum_xtbl',
    data_table_name      => 'items' );
END;
/

SELECT col, val FROM misssum_xtbl;

COL          VAL
-----
QTY          200

BEGIN
  DBMS_DATA_MINING_TRANSFORM.XFORM_MISS_NUM (
    miss_table_name      => 'misssum_xtbl',
    data_table_name      => 'items',
    xform_view_name      => 'items_view');
END;
/

SELECT * FROM items_view;

ITEM_ID      QTY
-----
aa           200
bb           200
cc           250
dd           200
ee           200
ff           100
gg           250
hh           200
ii           200
jj           200

```

### 49.6.39 XFORM\_NORM\_LIN Procedure

This procedure creates a view that implements the linear normalization transformations specified in a definition table. Only the columns that are specified in the definition table are

transformed; the remaining columns from the data table are present in the view, but they are not changed.

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_NORM_LIN (
    norm_table_name      IN VARCHAR2,
    data_table_name      IN VARCHAR2,
    xform_view_name      IN VARCHAR2,
    norm_schema_name     IN VARCHAR2 DEFAULT NULL,
    data_schema_name     IN VARCHAR2 DEFAULT NULL,
    xform_schema_name    IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-49 XFORM\_NORM\_LIN Procedure Parameters**

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| norm_table_name   | Name of the transformation definition table for linear normalization. You can use the <a href="#">CREATE_NORM_LIN Procedure</a> to create the definition table. The table must be populated with transformation definitions before you call XFORM_NORM_LIN. To populate the table, you can use one of the INSERT procedures for normalization or you can write your own SQL. See <a href="#">Table 49-12</a> . |
| data_table_name   | Name of the table containing the data to be transformed                                                                                                                                                                                                                                                                                                                                                        |
| xform_view_name   | Name of the view to be created. The view presents columns in <i>data_table_name</i> with the transformations specified in <i>miss_table_name</i> .                                                                                                                                                                                                                                                             |
| norm_schema_name  | Schema of <i>miss_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                      |
| data_schema_name  | Schema of <i>data_table_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                      |
| xform_schema_name | Schema of <i>xform_view_name</i> . If no schema is specified, the current schema is used.                                                                                                                                                                                                                                                                                                                      |

## Usage Notes

See "[Operational Notes](#)".

## Examples

This example creates a view that normalizes the *cust\_year\_of\_birth* and *cust\_credit\_limit* columns. The data source consists of three columns from *sh.customer*.

```
CREATE OR REPLACE VIEW mining_data AS
    SELECT cust_id, cust_year_of_birth, cust_credit_limit
    FROM sh.customers;
```

```
describe mining_data
```

| Name               | Null?    | Type      |
|--------------------|----------|-----------|
| -----              | -----    | -----     |
| CUST_ID            | NOT NULL | NUMBER    |
| CUST_YEAR_OF_BIRTH | NOT NULL | NUMBER(4) |
| CUST_CREDIT_LIMIT  |          | NUMBER    |

```
SELECT * FROM mining_data WHERE cust_id > 104495
    ORDER BY cust_year_of_birth;
```

```

CUST_ID CUST_YEAR_OF_BIRTH CUST_CREDIT_LIMIT
-----
104496          1947          3000
104498          1954         10000
104500          1962         15000
104499          1970          3000

```

## 49.6.40 XFORM\_STACK Procedure

This procedure creates a view that implements the transformations specified by the stack. Only the columns and nested attributes that are specified in the stack are transformed. Any

remaining columns and nested attributes from the data table appear in the view without changes.

To create a list of objects that describe the transformed columns, use the [DESCRIBE\\_STACK Procedure](#).

#### See Also:

["Overview"](#)

*Oracle Data Mining User's Guide* for more information about data mining attributes

## Syntax

```
DBMS_DATA_MINING_TRANSFORM.XFORM_STACK (
    xform_list          IN      TRANSFORM_list,
    data_table_name     IN      VARCHAR2,
    xform_view_name     IN      VARCHAR2,
    data_schema_name    IN      VARCHAR2 DEFAULT NULL,
    xform_schema_name   IN      VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 49-50 XFORM\_STACK Procedure Parameters**

| Parameter         | Description                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------|
| xform_list        | The transformation list. See <a href="#">Table 49-1</a> for a description of the TRANSFORM_LIST object type. |
| data_table_name   | Name of the table containing the data to be transformed                                                      |
| xform_view_name   | Name of the view to be created. The view applies the transformations in xform_list to data_table_name.       |
| data_schema_name  | Schema of data_table_name. If no schema is specified, the current schema is used.                            |
| xform_schema_name | Schema of xform_view_name. If no schema is specified, the current schema is used.                            |

## Usage Notes

See ["Operational Notes"](#). The following sections are especially relevant:

- ["About Transformation Lists"](#)
- ["About Stacking"](#)
- ["Nested Data Transformations"](#)

## Examples

This example applies a transformation list to the view dmuser.cust\_info and shows how the data is transformed. The CREATE statement for cust\_info is shown in ["DESCRIBE\\_STACK Procedure"](#).

```
BEGIN
    dbms_data_mining_transform.CREATE_BIN_NUM ('birth_yr_bins');
```

```

dbms_data_mining_transform.INSERT_BIN_NUM_QTILE (
    bin_table_name => 'birth_yr_bins',
    data_table_name => 'cust_info',
    bin_num        => 6,
    exclude_list   => dbms_data_mining_transform.column_list(
                        'cust_id','country_id'));

END;
/
SELECT * FROM birth_yr_bins;

# DBMS\_DATAPUMP

The `DBMS_DATAPUMP` package is used to move all, or part of, a database between databases, including both data and metadata.

## See Also:

*Oracle Database Utilities* for more information on the concepts behind the `DBMS_DATAPUMP` API, how it works, and how it is implemented in the Data Pump Export and Import utilities

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Data Structures](#)
- [Summary of DBMS\\_DATAPUMP Subprograms](#)

## 50.1 DBMS\_DATAPUMP Overview

`DBMS_DATAPUMP` provides the following support and functionality.

- The source and target databases can have different hardware, operating systems, character sets, time zones, and versions.
- All object types and datatypes existing in Oracle Database 11g and higher are supported.
- Data and metadata can be transferred between databases without using any intermediary files.
- A subset of a database can be moved based upon object type and names of objects.
- Schema names, data file names, tablespace names, and data can be transformed at import time.
- Previously aborted export and import jobs can be restarted without duplicating or omitting any data or metadata from the original job.
- The resources applied to an export or import job can be modified.
- Data in an Oracle proprietary format can be unloaded and loaded.

## 50.2 DBMS\_DATAPUMP Security Model

Security for the DBMS\_DATAPUMP package is implemented through roles.

The DATAPUMP\_EXP\_FULL\_DATABASE and DATAPUMP\_IMP\_FULL\_DATABASE roles allow privileged users to take full advantage of the API. The Data Pump API will use these roles to determine whether privileged application roles should be assigned to the processes comprising the job.

- **DATAPUMP\_EXP\_FULL\_DATABASE**

The DATAPUMP\_EXP\_FULL\_DATABASE role affects only Export operations. It allows users running these operations to do the following:

- Perform the operation outside of the scope of their schema
- Monitor jobs that were initiated by another user
- Export objects (for example, TABLESPACE definitions) that unprivileged users cannot reference

Although the SYS schema does not have the DATAPUMP\_EXP\_FULL\_DATABASE role assigned to it, all security checks performed by Data Pump that require the DATAPUMP\_EXP\_FULL\_DATABASE role will also grant access to the SYS schema.

- **DATAPUMP\_IMP\_FULL\_DATABASE**

The DATAPUMP\_IMP\_FULL\_DATABASE role affects only Import and SQL\_FILE operations. It allows users running these operations to do the following:

- Perform the operation outside of the scope of their schema
- Monitor jobs that were initiated by another user
- Import objects (for example, DIRECTORY definitions) that unprivileged users cannot create

Although the SYS schema does not have the DATAPUMP\_IMP\_FULL\_DATABASE role assigned to it, all security checks performed by Data Pump that require the DATAPUMP\_IMP\_FULL\_DATABASE role will also grant access to the SYS schema.

## 50.3 DBMS\_DATAPUMP Constants

There are several public constants defined for use with the DBMS\_DATAPUMP.GET\_STATUS procedure. All such constants are defined as part of the DBMS\_DATAPUMP package. Any references to these constants must be prefixed by DBMS\_DATAPUMP. and followed by the symbols in the following lists:

### Mask Bit Definitions

The following mask bit definitions are used for controlling the return of data through the DBMS\_DATAPUMP.GET\_STATUS procedure.

- `KU$_STATUS_WIP CONSTANT BINARY_INTEGER := 1;`
- `KU$_STATUS_JOB_DESC CONSTANT BINARY_INTEGER := 2;`
- `KU$_STATUS_JOB_STATUS CONSTANT BINARY_INTEGER := 4;`
- `KU$_STATUS_JOB_ERROR CONSTANT BINARY_INTEGER := 8;`

### Dump File Type Definitions

The following definitions are used for identifying types of dump files returned through the `DBMS_DATAPUMP.GET_STATUS` procedure.

- `KU$_DUMPFILTYPE_DISK` CONSTANT BINARY\_INTEGER := 0;
- `KU$_DUMPFILTYPE_TEMPLATE` CONSTANT BINARY\_INTEGER := 3;

## 50.4 DBMS\_DATAPUMP Data Structures

The `DBMS_DATAPUMP` package defines `OBJECT` types. The types described in this section are defined in the `SYS` schema for use by the `GET_STATUS` function. *The way in which these types are defined and used may be different than what you are accustomed to. Be sure to read this section carefully.*

The collection of types defined for use with the `GET_STATUS` procedure are version-specific and include version information in the names of the types. Once introduced, these types will always be provided and supported in future versions of Oracle Database and will not change. However, in future releases of Oracle Database, new versions of these types might be created that provide new or different information. The new versions of these types will have different version information embedded in the type names.

For example, in Oracle Database 12c, Release 1 (12.1), there is a `sys.ku$_Status1210` type, and in the next Oracle Database release, there could be a `sys.ku$_Status1310` type defined. Both types could be used with the `GET_STATUS` procedure.

Public synonyms have been defined for each of the types used with the `GET_STATUS` procedure. This makes it easier to use the types and means that you do not have to be concerned with changes to the actual type names or schemas where they reside. Oracle recommends that you use these synonyms whenever possible.

For each of the types, there is a version-specific synonym and a generic synonym. For example, the version-specific synonym `ku$_Status1210` is defined for the `sys.ku$_Status1210` type.

The generic synonym always describes the latest version of that type. For example, in Oracle Database 12c, Release 1 (12.1), the generic synonym `ku$_Status` is defined as `ku$_Status1210`. In a future release, there might be a `ku$_Status1310` synonym for `sys.ku$_Status1310`. Because the `ku$_Status` generic synonym always points to the latest definition, it would then point to `ku$_Status1310` rather than to `ku$_Status1210`.

The choice of whether to use version-specific synonyms or generic synonyms makes a significant difference in how you work. Using version-specific names protects your code from changes in future releases of Oracle Database because those types will continue to exist and be supported. However, access to new information will require code changes to use new synonym names for each of the types. Using the generic names implies that you always want the latest definition of the types and are prepared to deal with changes in different releases of Oracle Database.

When the version of Oracle Database that you are using changes, any C code that accesses types through generic synonym names will need to be recompiled.

**Note:**

Languages other than PL/SQL must ensure that their type definitions are properly aligned with the version-specific definitions.

[GET\\_STATUS Procedure](#) for additional information about how types are used

## Data Structures — Object Types

The `DBMS_DATAPUMP` package defines the following kinds of `OBJECT` types:

- Worker Status Types
- Log Entry and Error Types
- Job Status Types
- Job Description Types
- Status Types

### Worker Status Types

The worker status types describe what each worker process in a job is doing. The schema, object name, and object type of an object being processed will be provided. For workers processing user data, the partition name for a partitioned table (if any), the number of bytes processed in the partition, and the number of rows processed in the partition are also returned. Workers processing metadata provide status on the last object that was processed. No status for idle threads is returned.

The `percent_done` refers to the amount completed for the current data item being processed. It is not updated for metadata objects.

The worker status types are defined as follows:

```
CREATE TYPE sys.ku$WorkerStatus1010 AS OBJECT
(
    worker_number    NUMBER,          -- Worker process identifier
    process_name     VARCHAR2(30),    -- Worker process name
    state            VARCHAR2(30),    -- Worker process state
    schema           VARCHAR2(30),    -- Schema name
    name             VARCHAR2(4000),  -- Object name
    object_type      VARCHAR2(200),   -- Object type
    partition        VARCHAR2(30),    -- Partition name
    completed_objects NUMBER,          -- Completed number of objects
    total_objects    NUMBER,          -- Total number of objects
    completed_rows   NUMBER,          -- Number of rows completed
    completed_bytes  NUMBER,          -- Number of bytes completed
    percent_done     NUMBER           -- Percent done current object
)

CREATE OR REPLACE PUBLIC SYNONYM ku$WorkerStatus1010
FOR sys.ku$WorkerStatus1010;
```

```
CREATE TYPE sys.ku$_WorkerStatus1020 AS OBJECT
(
    worker_number    NUMBER,          -- Worker process identifier
    process_name     VARCHAR2(30),    -- Worker process name
    state            VARCHAR2(30),    -- Worker process state
    schema           VARCHAR2(30),    -- Schema name
    name             VARCHAR2(4000),  -- Object name
    object_type      VARCHAR2(200),   -- Object type
    partition        VARCHAR2(30),    -- Partition name
    completed_objects NUMBER,          -- Completed number of objects
    total_objects    NUMBER,          -- Total number of objects
    completed_rows   NUMBER,          -- Number of rows completed
    completed_bytes  NUMBER,          -- Number of bytes completed
    percent_done     NUMBER,          -- Percent done current object
    degree           NUMBER           -- Degree of parallelism
)
```

```
CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatus1020

CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList
FOR ku$_WorkerStatusList1220;

```

## Log Entry and Error Types

These types provide informational and error text to attached clients and the log stream. The `ku$LogLine.errorNumber` type is set to NULL for informational messages but is specified for error messages. Each log entry may contain several lines of text messages.

The log entry and error types are defined as follows:

```

CREATE TYPE sys.ku$_LogLine1010 AS OBJECT (
    logLineNumber      NUMBER,

```

```

        errorNumber    NUMBER,
        LogText        VARCHAR2(2000))

```

```

CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine1010 FOR sys.ku$_LogLine1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine1020 FOR sys.ku$_LogLine1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine FOR ku$_LogLine1010;
CREATE TYPE sys.ku$_LogEntry1010 AS TABLE OF sys.ku$_LogLine1010

```

```

CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry1010 FOR sys.ku$_LogEntry1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry1020 FOR sys.ku$_LogEntry1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry FOR ku$_LogEntry1010;

```

## Job Status Types

The job status type returns status about a job. Usually, the status concerns a running job, but it could also be about a stopped job when a client attaches. It is typically requested at attach time, when the client explicitly requests status from interactive mode and every *N* seconds when the client has requested status periodically.

The job status types are defined as follows (`percent_done` applies to data only):

```

CREATE TYPE sys.ku$_JobStatus1010 IS OBJECT
(
    job_name          VARCHAR2(30),          -- Name of the job
    operation         VARCHAR2(30),          -- Current operation
    job_mode          VARCHAR2(30),          -- Current mode
    bytes_processed   NUMBER,                -- Bytes so far
    total_bytes       NUMBER,                -- Total bytes for job
    percent_done      NUMBER,                -- Percent done
    degree            NUMBER,                -- Of job parallelism
    error_count       NUMBER,                -- #errors so far
    state             VARCHAR2(30),          -- Current job state
    phase             NUMBER,                -- Job phase
    restart_count     NUMBER,                -- #Job restarts
    worker_status_list ku$_WorkerStatusList1010, -- For (non-idle)
                                                -- job worker processes
    files             ku$_DumpFileSet1010    -- Dump file info
)

CREATE OR REPLACE PUBLIC SYNONYM ku$_JobStatus1010 FOR sys.ku$_JobStatus1010;

CREATE TYPE sys.ku$_JobStatus1020 IS OBJECT
(
    job_name          VARCHAR2(30),          -- Name of the job
    operation         VARCHAR2(30),          -- Current operation
    job_mode          VARCHAR2(30),          -- Current mode
    bytes_processed   NUMBER,                -- Bytes so far
    total_bytes       NUMBER,                -- Total bytes for job
    percent_done      NUMBER,                -- Percent done

```
CREATE OR REPLACE PUBLIC SYNONYM ku$_JobStatus FOR ku$_JobStatus1220;
```

## Job Description Types

The job description type holds all the environmental information about the job such as parameter settings and dump file set members. There are a couple of subordinate types required as well.

The job description types are defined as follows:

```
CREATE TYPE sys.ku$_JobDesc1010 IS OBJECT
(
    job_name          VARCHAR2(30),          -- The job name
    guid              RAW(16),               -- The job GUID
    operation          VARCHAR2(30),          -- Current operation
    job_mode           VARCHAR2(30),          -- Current mode
    remote_link        VARCHAR2(4000),        -- DB link, if any
    owner              VARCHAR2(30),          -- Job owner
    instance           VARCHAR2(16),          -- The instance name
    db_version         VARCHAR2(30),          -- Version of objects
    creator_privs      VARCHAR2(30),          -- Privs of job
    start_time         DATE,                  -- This job start time
    max_degree         NUMBER,                -- Max. parallelism
    log_file           VARCHAR2(4000),        -- Log file name
    sql_file           VARCHAR2(4000),        -- SQL file name
    params             ku$_ParamValues1010    -- Parameter list
)
```

```
CREATE OR REPLACE PUBLIC SYNONYM ku$_JobDesc1010 FOR sys.ku$_JobDesc1010;
```

```
CREATE TYPE sys.ku$_JobDesc1020 IS OBJECT
(
    job_name          VARCHAR2(30),          -- The job name
    guid              RAW(16),               -- The job GUID
    operation          VARCHAR2(30),          -- Current operation
    job_mode           VARCHAR2(30),          -- Current mode
    remote_link        VARCHAR2(4000),        -- DB link, if any
    owner              VARCHAR2(30),          -- Job owner
    platform           VARCHAR2(101),         -- Current job platform
    exp_platform       VARCHAR2(101),         -- Export platform
    global_name        VARCHAR2(4000),        -- Current global name
    exp_global_name    VARCHAR2(4000),        -- Export global name
    instance           VARCHAR2(16),          -- The instance name
    db_version         VARCHAR2(30),          -- Version of objects
    exp_db_version     VARCHAR2(30),          -- Export version
    scn                NUMBER,                -- Job SCN
    creator_privs      VARCHAR2(30),          -- Privs of job

CREATE OR REPLACE PUBLIC SYNONYM ku$_JobDesc FOR ku$_JobDesc1220;

```

### Status Types

The status type is an aggregate of some the previous types defined and is the return value for the `GET_STATUS` call. The mask attribute indicates which types of information are being returned to the caller. It is created by a client's shadow process from information it retrieves off the status queue or directly from the master table.

For errors, the `ku$_LogEntry` that is returned has already had its log lines ordered for proper output. That is, the original `ku$_LogEntry` objects have been ordered from outermost context to innermost.

The status types are defined as follows:

```

CREATE TYPE sys.ku$_Status1010 IS OBJECT
(
    mask          NUMBER,          -- Status types present
    wip           ku$_LogEntry1010, -- Work in progress
    job_description ku$_JobDesc1010, -- Complete job description
    job_status     ku$_JobStatus1010, -- Detailed job status
    error         ku$_LogEntry1010 -- Multi-level context errors
)

CREATE OR REPLACE PUBLIC SYNONYM ku$_Status1010 FOR sys.ku$_Status1010;

CREATE TYPE sys.ku$_Status1020 IS OBJECT
(
    mask          NUMBER,          -- Status types present
    wip           ku$_LogEntry1010, -- Work in progress
    job_description ku$_JobDesc1020, -- Complete job description
    job_status     ku$_JobStatus1020, -- Detailed job status
    error         ku$_LogEntry1010 -- Multi-level context errors
)

CREATE OR REPLACE PUBLIC SYNONYM ku$_Status1020 FOR sys.ku$_Status1020;

CREATE TYPE sys.ku$_Status1120 IS OBJECT
(
    mask          NUMBER,          -- Status types present
    wip           ku$_LogEntry1010, -- Work in progress
    job_description ku$_JobDesc1020, -- Complete job description

```

## 50.5 Summary of DBMS\_DATAPUMP Subprograms

This table lists the DBMS\_DATAPUMP subprograms in alphabetical order and briefly describes them.

**Table 50-1 DBMS\_DATAPUMP Package Subprograms**

| Subprogram                                   | Description                                                                                                                                                                                                        |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ADD_FILE Procedure</a>           | Adds dump files to the dump file set for an Export, Import, or SQL_FILE operation. In addition to dump files, other types of files can also be added by using the FILETYPE parameter provided with this procedure. |
| <a href="#">ATTACH Function</a>              | Used to gain access to a Data Pump job that is in the Defining, Executing, Idling, or Stopped state                                                                                                                |
| <a href="#">DATA_FILTER Procedures</a>       | Specifies restrictions on the rows that are to be retrieved                                                                                                                                                        |
| <a href="#">DATA_REMAP Procedure</a>         | Specifies transformations to be applied to column data as it is exported from, or imported into, a database.                                                                                                       |
| <a href="#">DETACH Procedure</a>             | Specifies that the user has no further interest in using the handle                                                                                                                                                |
| <a href="#">GET_DUMPFILE_INFO Procedure</a>  | Retrieves information about a specified dump file                                                                                                                                                                  |
| <a href="#">GET_STATUS Procedure</a>         | Monitors the status of a job or waits for the completion of a job or for more details on API errors                                                                                                                |
| <a href="#">LOG_ENTRY Procedure</a>          | Inserts a message into the log file                                                                                                                                                                                |
| <a href="#">METADATA_FILTER Procedure</a>    | Provides filters that allow you to restrict the items that are included in a job                                                                                                                                   |
| <a href="#">METADATA_REMAP Procedure</a>     | Specifies a remapping to be applied to objects as they are processed in the specified job                                                                                                                          |
| <a href="#">METADATA_TRANSFORM Procedure</a> | Specifies transformations to be applied to objects as they are processed in the specified job                                                                                                                      |

**Table 50-1 (Cont.) DBMS\_DATAPUMP Package Subprograms**

| Subprogram                               | Description                                                                                                                                                               |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">OPEN Function</a>            | Declares a new job using the Data Pump API, the handle returned being used as a parameter for calls to all other procedures (but not to the <code>ATTACH</code> function) |
| <a href="#">SET_PARALLEL Procedure</a>   | Adjusts the degree of parallelism within a job                                                                                                                            |
| <a href="#">SET_PARAMETER Procedures</a> | Specifies job-processing options                                                                                                                                          |
| <a href="#">START_JOB Procedure</a>      | Begins or resumes execution of a job                                                                                                                                      |
| <a href="#">STOP_JOB Procedure</a>       | Terminates a job, but optionally, preserves the state of the job                                                                                                          |
| <a href="#">WAIT_FOR_JOB Procedure</a>   | Runs a job until it either completes normally or stops for some other reason                                                                                              |

## 50.5.1 ADD\_FILE Procedure

This procedure adds files to the dump file set for an Export, Import, or `SQL_FILE` operation or specifies the log file or the output file for a `SQL_FILE` operation.

### Syntax

```
DBMS_DATAPUMP.ADD_FILE (
    handle      IN NUMBER,
    filename    IN VARCHAR2,
    directory   IN VARCHAR2,
    filesize    IN VARCHAR2 DEFAULT NULL,
    filetype    IN NUMBER DEFAULT DBMS_DATAPUMP.KU$_FILE_TYPE_DUMP_FILE,
    reusefile   IN NUMBER DEFAULT NULL);
```

### Parameters

**Table 50-2 ADD\_FILE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle    | The handle of a job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| filename  | The name of the file being added. <code>filename</code> must be a simple filename without any directory path information. For dump files, the <code>filename</code> can include a substitution variable. See the following table for a description of available substitution variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| directory | The name of a directory object within the database that is used to locate <code>filename</code> . A <code>directory</code> must be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| filesize  | The size of the dump file that is being added. It may be specified as the number of bytes, number of kilobytes (if followed by K), number of megabytes (if followed by M), number of gigabytes (if followed by G) or number of terabytes (if followed by T). An Export operation will write no more than the specified number of bytes to the file. Once the file is full, it will be closed. If there is insufficient space on the device to write the specified number of bytes, the Export operation will fail, but it can be restarted. If not specified, <code>filesize</code> will default to an unlimited size. For Import and <code>SQL_FILE</code> operations, <code>filesize</code> is ignored. The minimum value for <code>filesize</code> is ten times the default Data Pump block size, which is 4 kilobytes. A <code>filesize</code> can only be specified for dump files. |

**Table 50-2 (Cont.) ADD\_FILE Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filetype  | The type of the file to be added. The legal values are as follows and must be preceded by DBMS_DATAPUMP.: <ul style="list-style-type: none"> <li>KU\$_FILE_TYPE_DUMP_FILE (dump file for a job)</li> <li>KU\$_FILE_TYPE_LOG_FILE (log file for a job)</li> <li>KU\$_FILE_TYPE_SQL_FILE (output for SQL_FILE job)</li> </ul> |
| reusefile | If 0, a preexisting file will cause an error. If 1, a preexisting file will be overwritten. If NULL, the default action for the file type will be applied (that is, dump files will not be overwritten). This parameter should only be non-NULL for dump files. The reusefile parameter is restricted to export jobs.       |

#### Substitution Variables

**Table 50-3 Substitution Variables Available for the Filename Parameter on DBMS\_DATAPUMP.ADD\_FILE**

| Substitution Variable | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %U                    | The %U is expanded in the resulting file names into a two-character, fixed-width, incrementing integer starting at 01. For example, the dump filename of export%U would cause export01, export02, export03, and so on, to be created depending on how many files are needed to perform the export. For filenames containing the % character, the % must be represented as %% to avoid ambiguity. |
| %d, %D                | Specifies the current day of the month from the Gregorian calendar in format DD.<br>Note: This substitution variable cannot be used in an import file name.                                                                                                                                                                                                                                      |
| %m, %M                | Specifies the month in the Gregorian calendar in format MM.<br>Note: This substitution variable cannot be used in an import file name.                                                                                                                                                                                                                                                           |
| %t, %T                | Specifies the year, month, and day in the Gregorian calendar in this format: YYYYMMDD.<br>Note: This substitution variable cannot be used in an import file name.                                                                                                                                                                                                                                |

**Table 50-3 (Cont.) Substitution Variables Available for the Filename Parameter on DBMS\_DATAPUMP.ADD\_FILE**

| Substitution Variable | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %l, %L                | <p>Specifies a system-generated unique file name.</p> <p>The file names can contain a substitution variable (%L), which implies that multiple files may be generated. The substitution variable is expanded in the resulting file names into a 2-digit, fixed-width, incrementing integer starting at 01 and ending at 99 which is the same as (%U). In addition, the substitution variable is expanded in the resulting file names into a 3-digit to 10-digit, variable-width, incrementing integers starting at 100 and ending at 2147483646. The width field is determined by the number of digits in the integer.</p> <p>For example if the current integer was 1, exp%Laa%L.dmp would resolve to</p> <p>exp01aa01.dmp<br/>exp02aa02.dmp</p> <p>and so forth up until 99. Then, the next file name would have 3 digits substituted:</p> <p>exp100aa100.dmp<br/>exp101aa101.dmp</p> <p>and so forth up until 999 where the next file would have 4 digits substituted. The substitution will continue up to the largest number substitution allowed, which is 2147483646.</p> |
| %Y, %Y                | <p>Specifies the year in this format: YYYY.</p> <p>Note: This substitution variable cannot be used in an import file name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Exceptions

- **INVALID\_HANDLE.** The specified handle is not attached to a Data Pump job.
- **INVALID\_ARGVAL.** An invalid value was supplied for an input parameter.
- **INVALID\_STATE.** The job is completing, or the job is past the defining state for an import or SQL\_FILE job or is past the defining state for LOG and SQL files.
- **INVALID\_OPERATION.** A dump file was specified for a Network Import or ESTIMATE\_ONLY export operation.
- **SUCCESS\_WITH\_INFO.** The procedure succeeded, but further information is available through the GET\_STATUS procedure.
- **NO\_SUCH\_JOB.** The specified job does not exist.

### Usage Notes

- Adds files to a Data Pump job. Three types of files may be added to jobs: Dump files to contain the data that is being moved, log files to record the messages associated with an operation, and SQL files to record the output of a SQL\_FILE operation. Log and SQL files will overwrite previously existing files. Dump files will never overwrite previously existing files. Instead, an error will be generated.
- Import and SQL\_FILE operations require that all dump files be specified during the definition phase of the job. For Export operations, dump files can be added at any time. For

example, if the user ascertains that the file space is running low during an Export, additional dump files may be added through this API. If the specified dump file already exists for an Export operation and `reusefile` is not set to 1, an error will be returned.

- For Export operations, the parallelism setting should be less than or equal to the number of dump files in the dump file set. If there are not enough dump files, the job will not be able to maximize parallelism to the degree specified by the `SET_PARALLEL` procedure.
- For Import operations, the parallelism setting should also be less than or equal to the number of dump files in the dump file set. If there are not enough dump files, the performance will not be optimal as multiple threads of execution try to access the same dump file.
- If the substitution variable (`%U`) is included in a filename, multiple dump files may be specified through a single call to `ADD_FILE`. For Export operations, the new dump files will be created as they are needed. Enough dump files will be created to allow all of the processes specified by the current `SET_PARALLEL` value to be active. If one of the dump files fills, it will be closed and a new dump file (with a new generated name) will be created to take its place. If multiple `ADD_FILES` with substitution variables have been specified for dump files in a job, they will be used to generate dump files in a round robin fashion. For example, if `expa%U`, `expb%U` and `expc%U` were all specified for a job having a parallelism of 6, the initial dump files created would look like: `expa01`, `expb01`, `expc01`, `expa02`, `expb02`, and `expc02`.
- If presented with dump file specifications, `expa%U`, `expb%U` and `expc%U`, an Import or `SQL_FILE` operation will begin by attempting to open the dump files, `expa01`, `expb01`, and `expc01`. If the dump file containing the master table is not found in this set, the operation will expand its search for dump files by incrementing the substitution variable and looking up the new filenames (for example, `expa02`, `expb02`, and `expc02`). The DataPump API will keep expanding the search until it locates the dump file containing the master table. If the DataPump API determines that the dump file does not exist or is not part of the current dump set at any iteration, the DataPump API will stop incrementing the substitution variable for the dump file specification that was in error. Once the master table is found, the master table will be used to ascertain when all of dump files in the dump file set have been located.

## 50.5.2 ATTACH Function

This function provides access to a previously created job.

### Syntax

```
DBMS_DATAPUMP.ATTACH(
    job_name      IN VARCHAR2 DEFAULT NULL,
    job_owner     IN VARCHAR2 DEFAULT NULL)
RETURN NUMBER;
```

### Parameters

**Table 50-4 ATTACH Function Parameters**

| Parameter             | Description                                                                                                                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>job_name</code> | The name of the job. The default is the job name owned by the user who is specified in the <code>job_owner</code> parameter (assuming that user has only one job in the Defining, Executing, or Idling states). |

**Table 50-4 (Cont.) ATTACH Function Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| job_owner | The user who originally started the job. If NULL, then the value defaults to the owner of the current session. To specify a job owner other than yourself, you must have either the DATAPUMP_EXP_FULL_DATABASE role (for export operations) or the DATAPUMP_IMP_FULL_DATABASE role (for import and SQL_FILE operations). Being a privileged user allows you to monitor another user's job, but you cannot restart another user's job. |

### Return Values

An opaque handle for the job. This handle is used as input to the following procedures:

ADD\_FILE, DATA\_FILTER, DETACH, GET\_STATUS, LOG\_ENTRY, METADATA\_FILTER, METADATA\_REMAP, METADATA\_TRANSFORM, SET\_PARALLEL, SET\_PARAMETER, START\_JOB, STOP\_JOB, and WAIT\_FOR\_JOB.

### Exceptions

- INVALID\_ARGVAL. An invalid value was supplied for an input parameter.
- OBJECT\_NOT\_FOUND. The specified job no longer exists or the user specified a job owned by another schema, but the user did not have the DATAPUMP\_EXP\_FULL\_DATABASE or DATAPUMP\_IMP\_FULL\_DATABASE role.
- SUCCESS\_WITH\_INFO. The function succeeded, but further information is available through the GET\_STATUS procedure.
- NO\_SUCH\_JOB. The specified job does not exist.

### Usage Notes

- If the job was in the Stopped state, then the job is placed into the Idling state. After the ATTACH succeeds, you can monitor the progress of the job or control the job. The stream of KU\$\_STATUS\_WIP and KU\$\_STATUS\_JOB\_ERROR messages returned through the GET\_STATUS procedure will be returned to the newly attached job starting at the approximate time of the client's attachment. There will be no repeating of status and error messages that were processed before the client attached to a job.
- If you want to perform a second attach to a job, then you must do so from a different session.
- If the ATTACH fails, then use a null handle in a subsequent call to GET\_STATUS for more information about the failure.

## 50.5.3 DATA\_FILTER Procedures

This procedure specifies restrictions on the rows that are to be retrieved.

### Syntax

```
DBMS_DATAPUMP.DATA_FILTER (
    handle      IN NUMBER,
    name        IN VARCHAR2,
    value       IN NUMBER,
    table_name  IN VARCHAR2 DEFAULT NULL,
    schema_name IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_DATAPUMP.DATA_FILTER(  
    handle      IN NUMBER,  
    name        IN VARCHAR2,  
    value       IN VARCHAR2,  
    table_name  IN VARCHAR2 DEFAULT NULL,  
    schema_name IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_DATAPUMP.DATA_FILTER(  
    handle      IN NUMBER,  
    name        IN VARCHAR2,  
    value       IN CLOB,  
    table_name  IN VARCHAR2 DEFAULT NULL,  
    schema_name IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 50-5 DATA\_FILTER Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle that is returned from the <code>OPEN</code> function                                                                                                                                                         |
| name        | The name of the filter                                                                                                                                                                                                  |
| value       | The value of the filter                                                                                                                                                                                                 |
| table_name  | The name of the table on which the data filter is applied. If no table name is supplied, the filter applies to all tables in the job.                                                                                   |
| schema_name | The name of the schema that owns the table on which the filter is applied. If no schema name is specified, the filter applies to all schemas in the job. If you supply a schema name you must also supply a table name. |

## Exceptions

- `INVALID_ARGVAL`. There can be several reasons for this message:
  - A bad filter name is specified
  - The mode is `TRANSPORTABLE`, which does not support data filters
  - The specified table does not exist
  - The filter has already been set for the specified values of `schema_name` and `table_name`
- `INVALID_STATE`. The user called `DATA_FILTER` when the job was not in the Defining state.
- `INCONSISTENT_ARGS`. The `value` parameter is missing or its datatype does not match the filter name. Or a schema name was supplied, but not a table name.
- `PRIVILEGE_ERROR`. A schema name was supplied, but the user did not have the `DATAPUMP_EXP_FULL_DATABASE` or `DATAPUMP_IMP_FULL_DATABASE` role.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

## Usage Notes

- Each data filter can only appear once in each table (for example, you cannot supply multiple `SUBQUERY` filters to a table) or once in each job. If different filters using the same

name are applied to both a particular table and to the whole job, the filter parameter supplied for the specific table will take precedence.

With the exception of the `INCLUDE_ROWS` filter, data filters are not supported on tables having nested tables or domain indexes defined upon them. Data filters are not supported in jobs performed in Transportable Tablespace mode.

The available data filters are described in [Table 50-6](#).

**Table 50-6 Data Filters**

| Name                        | Datatype | Operations that Support Filter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|----------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>INCLUDE_ROWS</code>   | NUMBER   | EXPORT, IMPORT                 | If nonzero, this filter specifies that user data for the specified table should be included in the job. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>PARTITION_EXPR</code> | TEXT     | EXPORT, IMPORT                 | <div>  <b>Note:</b><br/>In this description, the information about partitions also applies to subpartitions. </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>PARTITION_LIST</code> | TEXT     |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>SAMPLE</code>         | NUMBER   | EXPORT, IMPORT                 | <p>For Export jobs, these filters specify which partitions are unloaded from the database. For Import jobs, they specify which table partitions are loaded into the database. Partition names are included in the job if their names satisfy the specified expression (for <code>PARTITION_EXPR</code>) or are included in the list (for <code>PARTITION_LIST</code>). Whereas the expression version of the filter offers more flexibility, the list version provides for full validation of the partition names.</p> <p>Double quotation marks around partition names are required only if the partition names contain special characters.</p> <p><code>PARTITION_EXPR</code> is not supported on jobs across a network link.</p> <p>Default=All partitions are processed</p> <p>For Export jobs, specifies a percentage for sampling the data blocks to be moved. This filter allows subsets of large tables to be extracted for testing purposes.</p> |
| <code>SUBQUERY</code>       | TEXT     | EXPORT, IMPORT                 | Specifies a subquery that is added to the end of the <code>SELECT</code> statement for the table. If you specify a <code>WHERE</code> clause in the subquery, you can restrict the rows that are selected. Specifying an <code>ORDER BY</code> clause orders the rows dumped in the export which improves performance when migrating from heap-organized tables to index-organized tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 50.5.4 DATA\_REMAP Procedure

This procedure specifies transformations to be applied to column data as it is exported from, or imported into, a database.

### Syntax

```
DBMS_DATAPUMP.DATA_REMAP(  
    handle          IN NUMBER,  
    name            IN VARCHAR2,  
    table_name      IN VARCHAR2,  
    column          IN VARCHAR2,  
    remap_function  IN VARCHAR2,  
    schema          IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 50-7 DATA\_REMAP Procedure Parameters**

| Parameter      | Description                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle         | The handle of the current job. The current session must have previously attached to the handle through a call to an <code>OPEN</code> function.                 |
| name           | The name of the remap                                                                                                                                           |
| table_name     | The table containing the column to be remapped                                                                                                                  |
| column         | The name of the column to be remapped                                                                                                                           |
| remap_function | The meaning of <code>remap_function</code> is dependent upon the value of <code>name</code> . See <a href="#">Table 50-8</a> for a list of possible names.      |
| schema         | The schema containing the column to be remapped. If <code>NULL</code> , the remapping applies to all schemas moved in the job that contain the specified table. |

### Exceptions

- `INVALID_ARGVAL`. The mode is transportable (which does not support data modifications) or it has specified that no data to be included in the job. An invalid remap name was supplied.
- `INVALID_OPERATION`. Data remaps are only supported for Export and Import operations.
- `INVALID_STATE`. The `DATA_REMAP` procedure was called after the job started (that is, it was not in the defining state).
- `NO_SUCH_JOB`. The job handle is no longer valid.

### Usage Notes

- The `DATA_REMAP` procedure is only supported for Export and Import operations. It allows you to manipulate user data being exported or imported. The `name` of the remap determines the remap operation to be performed.
- For export operations, you might wish to define a data remap to obscure sensitive data such as credit card numbers from a dump file, but leave the remainder of the data so that it can be read. To accomplish this, the remapping should convert each unique source number into a distinct generated number. So that the mapping is consistent across the dump file set, the same function should be called for every column that contains the credit card number.

- For import operations, you might wish to define a data remap to reset the primary key when data is being merged into an existing table that contains colliding primary keys. A single remapping function should be provided for all columns defining or referencing the primary key to ensure that remapping is consistent.

 **Note:**

If the called function uses package state variables, then to ensure that remapping is performed consistently across all tables, the job should be run with a SET\_PARALLEL value of 1 and no restart operations should be performed.

The Data Remap functions are listed in [Table 50-8](#).

**Table 50-8 Names of Data Remap Functions**

| Name                         | Meaning of <code>remap_function</code>                                | Meaning                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>COLUMN_FUNCTION</code> | String having the format:<br>[ <code>schema.</code> ]package.function | The <code>name</code> parameter references a PL/SQL package function which is called to modify the data for the specified column. The function accepts a single parameter, which has the same datatype as the remapped column, and returns a value having the same datatype as the remapped column. Note that the default for the schema is the schema of the user performing the export. |

## 50.5.5 DETACH Procedure

This procedure specifies that the user has no further interest in using the handle.

### Syntax

```
DBMS_DATAPUMP.DETACH(  
    handle IN NUMBER);
```

### Parameters

**Table 50-9 DETACH Procedure Parameters**

| Parameter           | Description                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>handle</code> | The handle of the job. The current session must have previously attached to the handle through a call to either an <code>OPEN</code> or <code>ATTACH</code> function. |

### Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.

- `NO_SUCH_JOB`. The specified job does not exist.

### Usage Notes

- Through this call, you specify that you have no further interest in using the handle. Resources associated with a completed job cannot be reclaimed until all users are detached from the job. An implicit detach from a handle is performed when the user's session is exited or aborted. An implicit detach from a handle is also performed upon the expiration of the timeout associated with a `STOP_JOB` that was applied to the job referenced by the handle. All previously allocated `DBMS_DATAPUMP` handles are released when an instance is restarted.

## 50.5.6 GET\_DUMPFILE\_INFO Procedure

This procedure retrieves information about a specified dump file.

### Syntax

```
DBMS_DATAPUMP.GET_DUMPFILE_INFO(
    filename      IN VARCHAR2,
    directory     IN VARCHAR2,
    info_table    OUT ku$_dumpfile_info,
    filetype      OUT NUMBER);
```

### Parameters

**Table 50-10 GET\_DUMPFILE\_INFO Procedure Parameters**

| Parameter               | Description                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------|
| <code>filename</code>   | A simple filename with no directory path information                                                     |
| <code>directory</code>  | A directory object that specifies where the file can be found                                            |
| <code>info_table</code> | A PL/SQL table for storing information about the dump file                                               |
| <code>filetype</code>   | The type of file (Data Pump dump file, original Export dump file, external tables dump file, or unknown) |

### Exceptions

The `GET_DUMPFILE_INFO` procedure is a utility routine that operates outside the context of any Data Pump job. Exceptions are handled differently for this procedure than for procedures associated in some way with a Data Pump job. A full exception stack should be available directly, without the need to call the `GET_STATUS` procedure to retrieve the detailed information. The exception for this procedure is as follows:

- `NO_DUMPFILE_INFO`. Unable to retrieve dump file information as specified.

### Usage Notes

You can use the `GET_DUMPFILE_INFO` procedure to request information about a specific file. If the file is not recognized as any type of dump file, then a filetype of 0 (zero) is returned and the dump file `info_table` remains empty.

A filetype value of 1 indicates a Data Pump dump file. A filetype value of 2 indicates an original Export dump file. A filetype value of 3 indicates an external tables dump file. In all cases, the dump file `info_table` will be populated with information retrieved from the dump file header. Rows of this table consist of item code and value pairs, where the item code indicates the type

of information and the value column is a VARCHAR2 containing the actual data (converted to a string in some cases). The table is defined as follows:

```
CREATE TYPE sys.ku$_dumpfile_item IS OBJECT (
    item_code      NUMBER,          -- Identifies header item
    value          VARCHAR2(2048)   -- Text string value)/

GRANT EXECUTE ON sys.ku$_dumpfile_item TO PUBLIC;
CREATE OR REPLACE PUBLIC SYNONYM ku$_dumpfile_item FOR sys.ku$_dumpfile_item;

CREATE TYPE sys.ku$_dumpfile_info AS TABLE OF sys.ku$_dumpfile_item/

GRANT EXECUTE ON sys.ku$_dumpfile_info TO PUBLIC;
CREATE OR REPLACE PUBLIC SYNONYM ku$_dumpfile_info FOR sys.ku$_dumpfile_info;
```

The item codes, which can easily be extended to provide more information as needed, are currently defined as shown in [Table 50-11](#) (prepended with the package name, DBMS\_DATAPUMP.). Assume the following with regard to these item codes:

- Unless otherwise stated, all item codes may be returned only for Oracle Data Pump and external tables dump files (filetypes 1 and 3).
- Unless otherwise stated, all item codes have been available since Oracle Database 10g Release 2 (10.2).

**Table 50-11 Item Codes For the DBMS\_DATAPUMP.GET\_DUMPFILE\_INFO Procedure**

| Item Code                 | Description                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KU\$_DFHDR_FILE_VERSION   | The internal file version of the dump file.                                                                                                                                                                   |
| KU\$_DFHDR_MASTER_PRESENT | If the Data Pump master table is present in the dump file, then the value for this item code is 1; otherwise the value is 0. Returned only for filetype 1.                                                    |
| KU\$_DFHDR_GUID           | A unique identifier assigned to the Data Pump export job or the external tables unload job that produced the dump file. For a multifile dump set, each file in the set has the same value for this item code. |
| KU\$_DFHDR_FILE_NUMBER    | A numeric identifier assigned to the dump file. Each dump file in a multifile dump set has its own identifier, unique only within the dump set.                                                               |
| KU\$_DFHDR_CHARSET_ID     | A numeric code that represents the character set in use at the source system when the dump file was created.<br>Returned for all filetypes.                                                                   |
| KU\$_DFHDR_CREATION_DATE  | The date and time that the dump file was created.                                                                                                                                                             |
| KU\$_DFHDR_FLAGS          | Internal flag values.                                                                                                                                                                                         |
| KU\$_DFHDR_JOB_NAME       | The name assigned to the export job that created the dump file.<br>Returned only for filetype 1.                                                                                                              |
| KU\$_DFHDR_PLATFORM       | The operating system name of the source system on which the dump file was created.                                                                                                                            |
| KU\$_DFHDR_INSTANCE       | The instance name of the source system on which the dump file was created.                                                                                                                                    |
| KU\$_DFHDR_LANGUAGE       | The language name that corresponds to the character set of the source system where the export dump file was created.                                                                                          |
| KU\$_DFHDR_BLOCKSIZE      | The blocksize, in bytes, of the dump file.                                                                                                                                                                    |
| KU\$_DFHDR_DIRPATH        | If direct path mode was used when the dump file was created, then the value for this item code is 1, otherwise the value is 0.<br>Returned only for filetype 2.                                               |

**Table 50-11 (Cont.) Item Codes For the DBMS\_DATAPUMP.GET\_DUMPFILE\_INFO Procedure**

| Item Code                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KU\$_DFHDR_METADATA_COMPRESSED | <p>If the system metadata is stored in the dump file in compressed format, then the value for this item code is 1, otherwise the value is 0.</p> <p>Returned only for filetype 1.</p>                                                                                                                                                                                                                                                                                                                                               |
| KU\$_DFHDR_DB_VERSION          | <p>The database job version used to create the dump file.</p> <p>Returned for all filetypes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| KU\$_DFHDR_MASTER_PIECE_COUNT  | <p>The Data Pump master table may be split into multiple pieces and written to multiple dump files in the set, one piece per file. The value returned for this item code indicates the number of dump files that contain pieces of the master table. The value for this item code is only meaningful if the Data Pump master table is present in the dump file, as indicated by the item code KU\$_DFHDR_MASTER_PRESENT.</p> <p>Returned only for filetype 1.</p> <p>Only available since Oracle Database 11g Release 1 (11.1).</p> |
| KU\$_DFHDR_MASTER_PIECE_NUMBER | <p>The Data Pump master table may be split into multiple pieces and written to multiple dump files in the set, one piece per file. The value returned for this item code indicates which master table piece is contained in the dump file. The value for this item code is only meaningful if the Data Pump master table is present in the dump file, as indicated by the item code KU\$_DFHDR_MASTER_PRESENT.</p> <p>Returned only for filetype 1.</p> <p>Only available since Oracle Database 11g Release 1 (11.1).</p>           |
| KU\$_DFHDR_DATA_COMPRESSED     | <p>If the table data is stored in the dump file in compressed format, then the value for this item code is 1, otherwise the value is 0.</p> <p>Only available since Oracle Database 11g Release 1 (11.1).</p>                                                                                                                                                                                                                                                                                                                       |
| KU\$_DFHDR_METADATA_ENCRYPTED  | <p>If the system metadata is stored in the dump file in encrypted format, then the value for this item code is 1, otherwise the value is 0.</p> <p>Returned only for filetype 1.</p> <p>Only available since Oracle Database 11g Release 1 (11.1).</p>                                                                                                                                                                                                                                                                              |
| KU\$_DFHDR_DATA_ENCRYPTED      | <p>If the table data is stored in the dump file in encrypted format, then the value for this item code is 1, otherwise the value is 0.</p> <p>Only available since Oracle Database 11g Release 1 (11.1).</p>                                                                                                                                                                                                                                                                                                                        |

## 50.5.7 GET\_STATUS Procedure

This procedure monitors the status of a job or waits for the completion of a job.

### Syntax

```
DBMS_DATAPUMP.GET_STATUS(
    handle      IN NUMBER,
    mask        IN BINARY_INTEGER,
    timeout     IN NUMBER DEFAULT NULL,
    job_state   OUT VARCHAR2,
    status      OUT ku$_Status);
```

## Parameters

**Table 50-12 GET\_STATUS Procedure Parameters**

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle    | The handle of a job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function. A null handle can be used to retrieve error information after <code>OPEN</code> and <code>ATTACH</code> failures.                                                                                                                                                                 |
| mask      | <p>A bit mask that indicates which of four types of information to return:</p> <ul style="list-style-type: none"> <li>• <code>KU\$_STATUS_WIP</code></li> <li>• <code>KU\$_STATUS_JOB_DESC</code></li> <li>• <code>KU\$_STATUS_JOB_STATUS</code></li> <li>• <code>KU\$_STATUS_JOB_ERROR</code></li> </ul> <p>Each status has a numerical value. You can request multiple types of information by adding together different combinations of values.</p> |
| timeout   | Maximum number of seconds to wait before returning to the user. A value of 0 requests an immediate return. A value of -1 requests an infinite wait. If <code>KU\$_STATUS_WIP</code> or <code>KU\$_STATUS_JOB_ERROR</code> information is requested and becomes available during the timeout period, then the procedure returns before the timeout period is over.                                                                                      |
| job_state | Current state of the job. If only the job state is needed, it is much more efficient to use this parameter than to retrieve the full <code>ku\$_Status</code> structure.                                                                                                                                                                                                                                                                               |
| status    | A <code>ku\$_Status</code> is returned. The <code>ku\$_Status</code> mask indicates what kind of information is included. This could be none if only <code>KU\$_STATUS_WIP</code> or <code>KU\$_STATUS_JOB_ERROR</code> information is requested and the timeout period expires.                                                                                                                                                                       |

## Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID_VALUE`. The mask or timeout contains an illegal value.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

## Usage Notes

The `GET_STATUS` procedure is used to monitor the progress of an ongoing job and to receive error notification. You can request various type of information using the mask parameter. The `KU$_STATUS_JOB_DESC` and `KU$_STATUS_JOB_STATUS` values are classified as synchronous information because the information resides in the master table. The `KU$_STATUS_WIP` and `KU$_STATUS_JOB_ERROR` values are classified as asynchronous because the messages that embody these types of information can be generated at any time by various layers in the Data Pump architecture.

- If synchronous information *only* is requested, the interface will ignore the timeout parameter and simply return the requested information.
- If asynchronous information is requested, the interface will wait a *maximum* of timeout seconds before returning to the client. If a message of the requested asynchronous information type is received, the call will complete prior to timeout seconds. If synchronous information was also requested, it will be returned whenever the procedure returns.

- If the `job_state` returned by `GET_STATUS` does not indicate a terminating job, it is possible that the job could still terminate before the next call to `GET_STATUS`. This would result in an `INVALID_HANDLE` exception. Alternatively, the job could terminate during the call to `GET_STATUS`, which would result in a `NO_SUCH_JOB` exception. Callers should be prepared to handle these cases.

### Error Handling

There are two types of error scenarios that need to be handled using the `GET_STATUS` procedure:

- Errors resulting from other procedure calls: For example, the `SET_PARAMETER` procedure may produce an `INCONSISTENT_ARGS` exception. The client should immediately call `GET_STATUS` with `mask=8 (errors)` and `timeout=0`. The returned `ku$Status.error` will contain a `ku$LogEntry` that describes the inconsistency in more detail.
- Errors resulting from events asynchronous to the client(s): An example might be `Table already exists` when trying to create a table. The `ku$Status.error` will contain a `ku$LogEntry` with all error lines (from all processing layers that added context about the error) properly ordered.

After a job has begun, a client's main processing loop will typically consist of a call to `GET_STATUS` with an infinite timeout (-1) "listening" for `KU$STATUS_WIP` and `KU$STATUS_JOB_ERROR` messages. If status was requested, then `JOB_STATUS` information will also be in the request.

When the `ku$Status` is interpreted, the following guidelines should be used:

- `ku$Status.ku$JobStatus.percent_done` refers only to the amount of data that has been processed in a job. Metadata is not considered in the calculation. It is determined using the following formulas:
  - `EXPORT` or `network IMPORT`-- $(\text{bytes\_processed} / \text{estimated\_bytes}) * 100$
  - `IMPORT`-- $(\text{bytes\_processed} / \text{total\_expected\_bytes}) * 100$
  - `SQL_FILE` or `estimate-only EXPORT`--0.00 if not done or 100.00 if done

The effects of the `QUERY` and `PARTITION_EXPR` data filters are not considered in computing `percent_done`.

It is expected that the status returned will be transformed by the caller into more user-friendly status. For example, when percent done is not zero, an estimate of completion time could be produced using the following formula:

```
((SYSDATE - start time) / ku$Status.ku$JobStatus.percent_done) * 100
```

- The caller should not use `ku$Status.ku$JobStatus.percent_done` for determining whether the job has completed. Instead, the caller should only rely on the state of the job as found in `job_state`.

## 50.5.8 LOG\_ENTRY Procedure

This procedure inserts a message into the log file.

### Syntax

```
DBMS_DATAPUMP.LOG_ENTRY (
  handle          IN NUMBER,
  message         IN VARCHAR2
  log_file_only   IN NUMBER DEFAULT 0);
```

## Parameters

**Table 50-13 LOG\_ENTRY Procedure Parameters**

| Parameter     | Description                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| handle        | The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function.  |
| message       | A text line to be added to the log file                                                                                                     |
| log_file_only | Specified text should be written only to the log file. It should not be returned in GET_STATUS work-in-progress (KU\$_STATUS_WIP) messages. |

## Exceptions

- INVALID\_HANDLE. The specified handle is not attached to a Data Pump job.
- SUCCESS\_WITH\_INFO. The procedure succeeded, but further information is available through the GET\_STATUS procedure.
- NO\_SUCH\_JOB. The specified job does not exist.

## Usage Notes

The message is added to the log file. If log\_file\_only is zero (the default), the message is also broadcast as a KU\$\_STATUS\_WIP message through the GET\_STATUS procedure to all users attached to the job.

The LOG\_ENTRY procedure allows applications to tailor the log stream to match the abstractions provided by the application. For example, the command-line interface supports INCLUDE and EXCLUDE parameters defined by the user. Identifying these values as calls to the underlying METADATA\_FILTER procedure would be confusing to users. Instead, the command-line interface can enter text into the log describing the settings for the INCLUDE and EXCLUDE parameters.

Lines entered in the log stream from LOG\_ENTRY are prefixed by the string, ";;; "

## 50.5.9 METADATA\_FILTER Procedure

This procedure provides filters that allow you to restrict the items that are included in a job.

### Syntax

```
DBMS_DATAPUMP.METADATA_FILTER(
    handle      IN NUMBER,
    name        IN VARCHAR2,
    value       IN VARCHAR2,
    object_path IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_DATAPUMP.METADATA_FILTER(
    handle      IN NUMBER,
    name        IN VARCHAR2,
    value       IN CLOB,
    object_path IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 50-14 METADATA\_FILTER Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle returned from the OPEN function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| name        | The name of the filter. See <a href="#">Table 50-15</a> for descriptions of the available filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| value       | The value of the filter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| object_path | <p>The object path to which the filter applies. If the default is used, the filter applies to all applicable objects. Lists of the object paths supported for each mode are contained in the catalog views for DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, and TABLE_EXPORT_OBJECTS. (Note that the TABLE_EXPORT_OBJECTS view is applicable to both Table and Tablespace mode because their object paths are the same.)</p> <p>For an import operation, object paths reference the mode used to create the dump file rather than the mode being used for the import.</p> |

[Table 50-15](#) describes the name, the object type, and the meaning of the filters available with the METADATA\_FILTER procedure. The datatype for all the filters is a text expression. All operations support all filters.

**Table 50-15 Filters Provided by METADATA\_FILTER Procedure**

| Name                               | Object Type                                      | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME_EXPR<br>NAME_LIST             | Named objects                                    | <p>Defines which object names are included in the job. You use the object type parameter to limit the filter to a particular object type.</p> <p>For Table mode, identifies which tables are to be processed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SCHEMA_EXPR<br>SCHEMA_LIST         | Schema objects                                   | <p>Restricts the job to objects whose owning schema name is satisfied by the expression.</p> <p>For Table mode, only a single SCHEMA_EXPR filter is supported. If specified, it must only specify a single schema (for example, 'IN ('SCOTT')').</p> <p>For Schema mode, identifies which users are to be processed.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| TABLESPACE_EXPR<br>TABLESPACE_LIST | TABLE,<br>CLUSTER,<br>INDEX,<br>ROLLBACK_SEGMENT | <p>Restricts the job to objects stored in a tablespace whose name is satisfied by the expression.</p> <p>For Tablespace mode, identifies which tablespaces are to be processed. If a partition of an object is stored in the tablespace, the entire object is added to the job.</p> <p>For Transportable mode, identifies which tablespaces are to be processed. If a table has a single partition in the tablespace set, all partitions must be in the tablespace set. An index is not included within the tablespace set unless all of its partitions are in the tablespace set. A domain index is not included in the tablespace set unless all of its secondary objects are included in the tablespace set.</p> |

**Table 50-15 (Cont.) Filters Provided by METADATA\_FILTER Procedure**

| Name              | Object Type   | Meaning                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INCLUDE_PATH_EXPR | All           | Defines which object paths are included in, or excluded from, the job. You use these filters to select only certain object types from the database or dump file set. Objects of paths satisfying the condition are included (INCLUDE_PATH_*) or excluded (EXCLUDE_PATH_*) from the operation. The object_path parameter is not supported for these filters. |
| INCLUDE_PATH_LIST |               |                                                                                                                                                                                                                                                                                                                                                             |
| EXCLUDE_PATH_EXPR |               |                                                                                                                                                                                                                                                                                                                                                             |
| EXCLUDE_PATH_LIST |               |                                                                                                                                                                                                                                                                                                                                                             |
| EXCLUDE_TABLES    | TABLE_EXPORTS | Specifies that no tables are to be exported.<br>The EXCLUDE_TABLES parameter is needed only when VIEWS_AS_TABLES is specified, and when there are no tables in a table mode export.                                                                                                                                                                         |
| VIEWS_AS_TABLES   | TABLE_EXPORTS | A comma-separated list of views that you want to be exported as tables:<br>[schema_name.]view_name[table_name]<br>The filter can be called multiple times with multiple values. All values are added to a list. All views on the list are exported as tables.                                                                                               |

### Exceptions

- **INVALID\_HANDLE.** The specified handle is not attached to a Data Pump job.
- **INVALID\_ARGVAL.** This exception can indicate any of the following conditions:
  - An object\_path was specified for an INCLUDE\_PATH\_EXPR or EXCLUDE\_PATH\_EXPR filter.
  - The specified object\_path is not supported for the current mode.
  - The SCHEMA\_EXPR filter specified multiple schemas for a Table mode job.
- **INVALID\_STATE.** The user called the METADATA\_FILTER procedure after the job left the defining state.
- **INCONSISTENT\_ARGS.** The filter value is of the wrong datatype, or the filter is missing.
- **SUCCESS\_WITH\_INFO.** The procedure succeeded, but further information is available through the GET\_STATUS procedure.
- **NO\_SUCH\_JOB.** The specified job does not exist.

### Usage Notes

- Metadata filters identify a set of objects that you want to be included or excluded from an Oracle Data Pump operation. Except for EXCLUDE\_PATH\_EXPR and INCLUDE\_PATH\_EXPR, dependent objects of an identified object will be processed along with the identified object. For example, if an index is identified for inclusion by a filter, then grants on that index will also be included by the filter. Likewise, if a table is excluded by a filter, then indexes, constraints, grants and triggers on the table will also be excluded by the filter.
- Two versions of each filter are supported: SQL expression and List. The SQL expression version of the filters offer maximum flexibility for identifying objects (for example the use of LIKE to support use of wild cards). The names of the expression filters are as follows:

- NAME\_EXPR
- SCHEMA\_EXPR
- TABLESPACE\_EXPR
- INCLUDE\_PATH\_EXPR
- EXCLUDE\_PATH\_EXPR

The list version of the filters allow maximum validation of the filter. An error will be reported if one of the elements in the filter is not found within the source database (for Export and network-based jobs) or is not found within the dump file (for file-based Import and SQLFILE jobs). The names of the list filters are as follows:

- NAME\_LIST
- SCHEMA\_LIST
- TABLESPACE\_LIST
- INCLUDE\_PATH\_LIST
- EXCLUDE\_PATH\_LIST

- Filters allow a user to restrict the items that are included in a job. For example, a user could request a full export, but without Package Specifications or Package Bodies.
- If multiple filters are specified for a object type, they are implicitly 'ANDed' together (that is, objects participating in the job must pass all of the filters applied to their object types).
- The same filter name can be specified multiple times within a job. For example, specifying NAME\_EXPR as '!='EMP'' and NAME\_EXPR as '!='DEPT'' on a Table mode export would produce a file set containing all of the tables except for EMP and DEPT.
- EXCLUDE\_TABLES is only used in concert with VIEWS\_AS\_TABLES, so that you can exclude tables from an export while enabling exports of views as tables. For example, if the only thing you want to do is to export the contents of a view as a table, then you can use VIEWS\_AS\_TABLES to export the views, but not the tables. If you want to export some actual tables, and you also want export other views as tables, then you would select VIEWS\_AS\_TABLES, but not select EXCLUDE\_TABLES.

## DBMS\_DATAPUMP Examples

In the following example, we use the metadata filters EXCLUDE\_TABLES with VIEWS\_AS\_TABLES to export a view as a table, while excluding the table from which the view is created.

Suppose you have a view called SCOTT.EMPV that is defined for a specific set of columns in the table SCOTT.EMP (for example, only the columns empno, ename and hiredate). You want to export that view as a table to a target database using the Oracle Data Pump API, so that you only expose that subset of columns from SCOTT.EMP in your export. In this case, you can run the export as follows:

```
BEGIN
  h := dbms_datapump.open('EXPORT' , 'TABLE');
  dbms_datapump.metadata_filter(h, 'EXCLUDE_TABLES', 'Y');
  dbms_datapump.metadata_filter(h, 'VIEWS_AS_TABLES', 'SCOTT.EMPV');
  :
  :
  :
  dbms_datapump.start_job(h, 0, 0);
```

:

If you don't use the `EXCLUDE_TABLES` filter, then the job fails, because there are no tables included in a table-model export. However, because we only want to export the view `SCOTT.EMPV` as if it was a table, and we specifically do not want to export the table `SCOTT.EMP`, we set `EXCLUDE_TABLES`. The tables in the source are excluded, and the view `SCOTT.EMPV` is exported to the target as a table.

## 50.5.10 METADATA\_REMAP Procedure

This procedure specifies a remapping to be applied to objects as they are processed in the specified job.

### Syntax

```
DBMS_DATAPUMP.METADATA_REMAP (
    handle      IN NUMBER,
    name        IN VARCHAR2,
    old_value   IN VARCHAR2,
    value       IN VARCHAR2,
    object_type IN VARCHAR2 DEFAULT NULL);
```

### Parameters

**Table 50-16 METADATA\_REMAP Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle for the current job. The current session must have previously attached to the handle through a call to the <code>OPEN</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| name        | The name of the remap. See <a href="#">Table 50-17</a> for descriptions of the available remaps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| old_value   | Specifies which value in the dump file set should be reset to <code>value</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| value       | The value of the parameter for the remap. This signifies the new value that <code>old_value</code> should be translated into.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| object_type | Designates the object type to which the remap applies. The list of object types supported for each mode are contained in the <code>DATABASE_EXPORT_OBJECTS</code> , <code>SCHEMA_EXPORT_OBJECTS</code> , <code>TABLE_EXPORT_OBJECTS</code> , and <code>TABLESPACE_EXPORT_OBJECTS</code> catalog views.<br><br>By default, the remap applies to all applicable objects within the job. The <code>object_type</code> parameter allows a caller to specify different parameters for different object types within a job. Remaps that explicitly specify an object type override remaps that apply to all object types. |

[Table 50-17](#) describes the remaps provided by the `METADATA_REMAP` procedure.

**Table 50-17 Remaps Provided by the METADATA\_REMAP Procedure**

| Name             | Datatype | Object Type                                                                           | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|----------|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REMAP_SCHEMA     | TEXT     | Schema objects                                                                        | <p>Any schema object in the job that matches the <code>object_type</code> parameter and was located in the <code>old_value</code> schema will be moved to the <code>value</code> schema.</p> <p>Privileged users can perform unrestricted schema remaps.</p> <p>Nonprivileged users can perform schema remaps only if their schema is the target schema of the remap.</p> <p>For example, SCOTT can remap his BLAKE's objects to SCOTT, but SCOTT cannot remap SCOTT's objects to BLAKE.</p>                                |
| REMAP_TABLESPACE | TEXT     | TABLE, INDEX, ROLLBACK_SEGMENT, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, TABLE_SPACE | <p>Any storage segment in the job that matches the <code>object_type</code> parameter and was located in the <code>old_value</code> tablespace will be relocated to the <code>value</code> tablespace.</p>                                                                                                                                                                                                                                                                                                                  |
| REMAP_DATAFILE   | TEXT     | LIBRARY, TABLESPACE, DIRECTORY                                                        | <p>If <code>old_value</code> and <code>value</code> are both full file specifications, then any data file reference in the job that matches the <code>object_type</code> parameter and that referenced the <code>old_value</code> data file will be redefined to use the <code>value</code> data file. If <code>old_value</code> and <code>value</code> are both directory paths, then any data file reference whose object path matches <code>old_value</code> will have its path substituted with <code>value</code>.</p> |
| REMAP_TABLE      | TEXT     | TABLE                                                                                 | <p>Any reference to a table in the job that matches the <code>old_value</code> table name will be replaced with the <code>value</code> table name. The <code>old_value</code> parameter may refer to a partition such as <code>employees.low</code>. This allows names for tables constructed the by <code>PARTITION_OPTIONS=DEPARTIT</code> <code>ION</code> parameter to be specified by the user.</p>                                                                                                                    |

#### Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID_ARGVAL`. This message can indicate any of the following:

- The job's mode does not include the specified `object_type`.
- The remap has already been specified for the specified `old_value` and `object_type`.
- `INVALID_OPERATION`. Remaps are only supported for `SQL_FILE` and Import operations. The job's operation was Export, which does not support the use of metadata remaps.
- `INVALID_STATE`. The user called `METADATA_REMAP` after the job had started (that is, the job was not in the defining state).
- `INCONSISTENT_ARGS`. There was no `value` supplied or it was of the wrong datatype for the remap.
- `PRIVILEGE_ERROR`. A nonprivileged user attempted to do a `REMAP_SCHEMA` to a different user's schema or a `REMAP_DATAFILE`.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

### Usage Notes

- The `METADATA_REMAP` procedure is only supported for Import and `SQL_FILE` operations. It enables you to apply commonly desired, predefined remappings to the definition of objects as part of the transfer. If you need remaps that are not supported within this procedure, you should do a preliminary `SQL_FILE` operation to produce a SQL script corresponding to the dump file set. By editing the DDL directly and then executing it, you can produce any remappings that you need.
- Transforms for the DataPump API are a subset of the remaps implemented by the `DBMS_METADATA.SET_TRANSFORM_PARAMETER` API. Multiple remaps can be defined for a single job. However, each remap defined must be unique according its parameters. That is, two remaps cannot specify conflicting or redundant remaps.

## 50.5.11 METADATA\_TRANSFORM Procedure

This procedure specifies transformations to be applied to objects as they are processed in the specified job.

### Syntax

```
DBMS_DATAPUMP.METADATA_TRANSFORM (
    handle      IN NUMBER,
    name        IN VARCHAR2,
    value       IN VARCHAR2,
    object_type IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_DATAPUMP.METADATA_TRANSFORM (
    handle      IN NUMBER,
    name        IN VARCHAR2,
    value       IN NUMBER,
    object_type IN VARCHAR2 DEFAULT NULL);
```

## Parameters

**Table 50-18 METADATA\_TRANSFORM Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle for the current job. The current session must have previously attached to the handle through a call to the <code>OPEN</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| name        | The name of the transformation. See <a href="#">Table 50-19</a> for descriptions of the available transforms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| value       | The value of the parameter for the transform                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| object_type | <p>Designates the object type to which the transform applies. The list of object types supported for each mode are contained in the <code>DATABASE_EXPORT_OBJECTS</code>, <code>SCHEMA_EXPORT_OBJECTS</code>, <code>TABLE_EXPORT_OBJECTS</code>, and <code>TABLESPACE_EXPORT_OBJECTS</code> catalog views.</p> <p>By default, the transform applies to all applicable objects within the job. The <code>object_type</code> parameter allows a caller to specify different transform parameters for different object types within a job. Transforms that explicitly specify an object type override transforms that apply to all object types.</p> |

[Table 50-19](#) describes the transforms provided by the `METADATA_TRANSFORM` procedure.

**Table 50-19 Transforms Provided by the METADATA\_TRANSFORM Procedure**

| Name                                 | Datatype | Object Type    | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|----------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DISABLE_ARCHIVE_LOGGING</code> | NUMBER   | TABLE<br>INDEX | <p>Specifies whether to disable archive logging for specified object types during import.</p> <p>A value of zero (<code>FALSE</code>) is the default. It specifies that archive logging will take place. This is the default behavior if this transform parameter is not specified.</p> <p>A non-zero (<code>TRUE</code>) value disables archive logging for the specified object types before data is loaded during import. If no object type is specified, then archive logging is disabled for both <code>TABLE</code> and <code>INDEX</code> object types. All other object types processed during data pump import are logged.</p> <p><b>Note:</b> If the database is in <code>FORCE LOGGING</code> mode, then the <code>DISABLE_ARCHIVE_LOGGING</code> transform does not disable logging when indexes and tables are created.</p> |

**Table 50-19 (Cont.) Transforms Provided by the METADATA\_TRANSFORM Procedure**

| Name            | Datatype | Object Type                                  | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INMEMORY        | NUMBER   | TABLE<br>TABLESPACE<br>MATERIALIZED<br>VIEWS | <p>The INMEMORY transform is related to the In-Memory Column Store (IM column store), an optional area in the SGA that stores whole tables, table partitions, and individual columns in a compressed columnar format.</p> <p>If a non-zero value (TRUE) is specified on import, then Data Pump generates an IM clause that preserves the IM setting those objects had at export time. This is the default.</p> <p>If a value of zero (FALSE) is specified on import, then Data Pump does not include an IM clause for any objects.</p> <p><b>Note:</b> The INMEMORY transform is available only in Oracle Database 12c Release 1 (12.1.0.2) or higher.</p> |
| INMEMORY_CLAUSE | TEXT     | TABLE<br>TABLESPACE<br>MATERIALIZED<br>VIEWS | <p>The INMEMORY_CLAUSE transform is related to the In-Memory Column Store (IM column store), an optional area in the SGA that stores whole tables, table partitions, and individual columns in a compressed columnar format.</p> <p>When you specify this transform, Data Pump uses the contents of the string as the IM clause for all objects being imported that have an IM clause in their DDL. This transform is useful when you want to override the IM clause for an object in the dump file.</p> <p><b>Note:</b> The INMEMORY_CLAUSE transform is available only in Oracle Database 12c Release (12.1.0.2) or higher.</p>                          |
| LOB_STORAGE     | TEXT     | TABLE                                        | <p>Specifies the storage type to use for LOB segments. The options are as follows:</p> <ul style="list-style-type: none"> <li>• SECUREFILE - LOB storage is returned as SECUREFILE</li> <li>• BASICFILE - LOB storage is returned as BASICFILE</li> <li>• DEFAULT - The keyword (SECUREFILE or BASICFILE) is omitted in the LOB STORE AS clause.</li> <li>• NO_CHANGE - LOB segments are created with the same storage they had in the source database. This is the default.</li> </ul> <p>Specifying this transform changes the LOB storage for all tables in the job, including tables that provide storage for materialized views.</p>                  |
| OID             | NUMBER   | TYPE<br>TABLE                                | <p>If zero, inhibits the assignment of the exported OID during type or table creation. Instead, a new OID will be assigned.</p> <p>Use of this transform on Object Tables will cause breakage in REF columns that point to the table.</p> <p>Defaults to 1.</p>                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 50-19 (Cont.) Transforms Provided by the METADATA\_TRANSFORM Procedure**

| Name                     | Datatype | Object Type                  | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|----------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCTSPACE                 | NUMBER   | TABLE<br>INDEX<br>TABLESPACE | Specifies a percentage multiplier used to alter extent allocations and data file sizes. Used to shrink large tablespaces for testing purposes. Defaults to 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SEGMENT_ATTRIBUTES       | NUMBER   | TABLE, INDEX                 | If nonzero (TRUE), emit storage segment parameters. Defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SEGMENT_CREATION         | NUMBER   | TABLE                        | If nonzero (TRUE), the SQL SEGMENT CREATION clause is added to the CREATE TABLE statement. That is, the CREATE TABLE statement will explicitly say either SEGMENT CREATION DEFERRED or SEGMENT CREATION IMMEDIATE.<br><br>If the value is FALSE, then the SEGMENT CREATION clause is omitted from the CREATE TABLE statement. Set this parameter to FALSE to use the default segment creation attributes for the table(s) being loaded. Defaults to nonzero (TRUE).                                                                                                                                                                                          |
| STORAGE                  | NUMBER   | TABLE                        | If nonzero (TRUE), emit storage clause. (Ignored if SEGMENT_ATTRIBUTES is zero.) Defaults to nonzero (TRUE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| TABLE_COMPRESSION Clause | TEXT     | TABLE                        | Specifies a table compression clause (for example, COMPRESS BASIC) to use when the table is created.<br><br>Specify NONE to omit the table compression clause. The table will have the default compression for the tablespace.<br><br>Specifying this transform changes the compression type for all tables in the job, including tables that provide storage for materialized views.                                                                                                                                                                                                                                                                        |
| XMLTYPE_STORAGE Clause   | TEXT     | TABLE                        | Specifies to use the TRANSPORTABLE BINARY XML XMLType. This new type is available with Oracle Database Cloud Service Release 21c and 19c for Cloud only. It is the recommended storage type for Oracle Database 23ai. This option stores the data in a self-contained binary format or the non-transportable compact BINARY XML storage XMLType for XML data storage. There is no default.<br><br>If the transform is not used, then the source datatype in the dumpfile is the datatype defined on the target.syntax:<br><br>dbms_datapump.metadata_transform<br>( handle => h1, name =><br>'XMLTYPE_STORAGE Clause', value =><br>'transform param value'); |

## Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID_ARGVAL`. This message can indicate any of the following:
  - The mode is transportable, which doesn't support transforms.
  - The job's mode does not include the specified `object_type`.
  - The transform has already been specified for the specified `value` and `object_type`.
- `INVALID_OPERATION`. Transforms are only supported for `SQL_FILE` and Import operations. The job's operation was Export which does not support the use of metadata transforms.
- `INVALID_STATE`. The user called `METADATA_TRANSFORM` after the job had started (that is, the job was not in the defining state).
- `INCONSISTENT_ARGS`. There was no `value` supplied or it was of the wrong datatype for the transform.
- `PRIVILEGE_ERROR`. A nonprivileged user attempted to do a `REMAP_SCHEMA` to a different user's schema or a `REMAP_DATAFILE`.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

## Usage Notes

- The `METADATA_TRANSFORM` procedure is only supported for Import and `SQL_FILE` operations. It enables you to apply commonly desired, predefined transformations to the definition of objects as part of the transfer. If you need transforms that are not supported within this procedure, you should do a preliminary `SQL_FILE` operation to produce a SQL script corresponding to the dump file set. By editing the DDL directly and then executing it, you can produce any transformations that you need.
- Transforms for the DataPump API are a subset of the transforms implemented by the `DBMS_METADATA.SET_TRANSFORM_PARAMETER` API. Multiple transforms can be defined for a single job. However, each transform defined must be unique according its parameters. That is, two transforms cannot specify conflicting or redundant transformations.
- In Oracle Database 23ai, Oracle recommends that you use the `TRANSPORTABLE BINARY XML XMLType` to store the data in a self-contained binary format. In Oracle Database 19c and 21c, you can use this XMLType in Cloud deployments. This XMLType does not store the metadata used to encode or decode XML data in a central table, which simplifies the XML data storage and makes it easier to transport. For more information about this XMLType, see *Oracle XML DB Developer's Guide*.

## 50.5.12 OPEN Function

This function is used to declare a new job using the Data Pump API.

The handle that is returned is used as a parameter for calls to all other procedures (but not to the `ATTACH` function).

## Syntax

```
DBMS_DATAPUMP.OPEN (
    operation      IN VARCHAR2,
    job_mode       IN VARCHAR2,
    remote_link    IN VARCHAR2 DEFAULT NULL,
    job_name       IN VARCHAR2 DEFAULT NULL,
    version        IN VARCHAR2 DEFAULT 'COMPATIBLE')
RETURN NUMBER;
```

## Parameters

**Table 50-20 OPEN Function Parameters**

| Parameter   | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| operation   | The type of operation to be performed. <a href="#">Table 50-21</a> contains descriptions of valid operation types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| job_mode    | The scope of the operation to be performed. <a href="#">Table 50-22</a> contains descriptions of valid modes. Specifying NULL generates an error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| remote_link | If the value of this parameter is non-null, it provides the name of a database link to the remote database that will be the source of data and metadata for the current job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| job_name    | <p>The name of the job. The name is limited to 128 characters; it will be truncated if more than 128 characters are used. It may consist of printable characters and spaces. It is implicitly qualified by the schema of the user executing the <code>OPEN</code> function and must be unique to that schema (that is, there cannot be other Data Pump jobs using the same name).</p> <p>The name is used to identify the job both within the API and with other database components such as identifying the job in the <code>DBA_RESUMABLE</code> view if the job becomes suspended through lack of resources. If no name is supplied, a system generated name will be provided for the job in the following format:<br/>"SYS_&lt;OPERATION&gt;_&lt;MODE&gt;_%N".</p> <p>The default job name is formed where %N expands to a two-digit incrementing integer starting at '01' (for example, "SYS_IMPORT_FULL_03"). The name supplied for the job will also be used to name the master table and other resources associated with the job.</p>                       |
| version     | <p>The version of database objects to be extracted. This option is only valid for Export, network Import, and SQL_FILE operations. Database objects or attributes that are incompatible with the version will not be extracted. Legal values for this parameter are as follows:</p> <ul style="list-style-type: none"> <li>• <code>COMPATIBLE</code> - (default) the version of the metadata corresponds to the database compatibility level and the compatibility release level for feature (as given in the <code>V\$COMPATIBILITY</code> view). Database compatibility must be set to 9.2 or higher.</li> <li>• <code>LATEST</code> - the version of the metadata corresponds to the database version.</li> <li>• A specific database version, for example, '11.0.0'.</li> </ul> <p>Specify a value of 12 to allow all existing database features, components, and options to be exported from Oracle Database 11g release 2 (11.2.0.3) or later into an Oracle Database 12 c Release 1 (12.1) (either a multitenant container database (CDB) or a non-CDB).</p> |

[Table 50-21](#) describes the valid operation types for the `OPEN` function.

**Table 50-21 Valid Operation Types for the OPEN Function**

| Operation | Description                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXPORT    | Saves data and metadata to a dump file set or obtains an estimate of the size of the data for an operation.                                                                            |
| IMPORT    | Restores data and metadata from a dump file set or across a database link.                                                                                                             |
| SQL_FILE  | Displays the metadata within a dump file set, or from across a network link, as a SQL script. The location of the SQL script is specified through the <code>ADD_FILE</code> procedure. |

Table 50-22 describes the valid modes for the `OPEN` function.

**Table 50-22 Valid Modes for the OPEN Function**

| Mode          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FULL          | Operates on the full database or full dump file set except for Oracle Database internal schemas. (Some tables from Oracle Database internal schemas may be registered to be exported and imported in full operations in order to provide consistent metadata during import.)<br>The <code>TRANSPORTABLE</code> parameter can be set to <code>ALWAYS</code> during a full database export in order to move data via transportable tablespaces rather than in the Data Pump dump file. |
| SCHEMA        | Operates on a set of selected schemas. Defaults to the schema of the current user. All objects in the selected schemas are processed. In <code>SCHEMA</code> mode, you cannot specify Oracle-internal schemas (for example, <code>SYS</code> , <code>XDB</code> , <code>ORDSYS</code> , <code>MDSYS</code> , <code>CTXSYS</code> , <code>ORDPLUGINS</code> , or <code>LBACSYS</code> ).                                                                                              |
| TABLE         | Operates on a set of selected tables. Defaults to all of the tables in the current user's schema. Only tables and their dependent objects are processed.                                                                                                                                                                                                                                                                                                                             |
| TABLESPACE    | Operates on a set of selected tablespaces. No defaulting is performed. Tables that have storage in the specified tablespaces are processed in the same manner as in Table mode.                                                                                                                                                                                                                                                                                                      |
| TRANSPORTABLE | Operates on metadata for tables (and their dependent objects) within a set of selected tablespaces to perform a transportable tablespace export/import.                                                                                                                                                                                                                                                                                                                              |

### Return Values

- An opaque handle for the job. This handle is used as input to the following procedures: `ADD_FILE`, `CREATE_JOB_VIEW`, `DATA_FILTER`, `DETACH`, `GET_STATUS`, `LOG_ENTRY`, `LOG_ERROR`, `METADATA_FILTER`, `METADATA_REMAP`, `METADATA_TRANSFORM`, `SET_PARALLEL`, `SET_PARAMETER`, `START_JOB`, `STOP_JOB`, and `WAIT_FOR_JOB`

### Exceptions

- `INVALID_ARGVAL`. An invalid operation or mode was specified. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `JOB_EXISTS`. A table already exists with the specified job name.

- `PRIVILEGE_ERROR`. The user does not have the necessary privileges or roles to use the specified mode.
- `INTERNAL_ERROR`. The job was created under the wrong schema or the master table was of the wrong format.
- `SUCCESS_WITH_INFO`. The function succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

#### Usage Notes

- When the job is created, a master table is created for the job under the caller's schema within the caller's default tablespace. A handle referencing the job is returned that attaches the current session to the job. Once attached, the handle remains valid until either an explicit or implicit detach occurs. The handle is only valid in the caller's session. Other handles can be attached to the same job from a different session by using the `ATTACH` function.
- If the call to the `OPEN` function fails, call the `GET_STATUS` procedure with a null handle to retrieve additional information about the failure.

## 50.5.13 SET\_PARALLEL Procedure

This procedure adjusts the degree of parallelism within a job.

#### Syntax

```
DBMS_DATAPUMP.SET_PARALLEL(  
    handle      IN NUMBER,  
    degree      IN NUMBER);
```

#### Parameters

**Table 50-23 SET\_PARALLEL Procedure Parameters**

| Parameter | Description                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle    | The handle of a job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function. |
| degree    | The maximum number of worker processes that can be used for the job. You use this parameter to adjust the amount of resources used for a job.                        |

#### Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID_OPERATION`. The `SET_PARALLEL` procedure is only valid for export and import operations.
- `INVALID_ARGVAL`. An invalid value was supplied for an input parameter.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

## Usage Notes

- The `SET_PARALLEL` procedure is only available in the Enterprise Edition of the Oracle database.
- The `SET_PARALLEL` procedure can be executed by any session attached to a job. The job must be in one of the following states: Defining, Idling, or Executing.
- The effect of decreasing the degree of parallelism may be delayed because ongoing work needs to find an orderly completion point before `SET_PARALLEL` can take effect.
- Decreasing the parallelism will not result in fewer worker processes associated with the job. It will only decrease the number of worker processes that will be executing at any given time.
- Increasing the parallelism will take effect immediately if there is work that can be performed in parallel.
- The degree of parallelism requested by a user may be decreased based upon settings in the resource manager or through limitations introduced by the `PROCESSES` or `SESSIONS` initialization parameters in the `init.ora` file.
- To parallelize an Export job to a degree of  $n$ , the user should supply  $n$  files in the dump file set or specify a substitution variable in a file specification. Otherwise, some of the worker processes will be idle while waiting for files.
- `SQL_FILE` operations always operate with a degree of 1. Jobs running in the Transportable mode always operate with a degree of 1.

## 50.5.14 SET\_PARAMETER Procedures

This procedure is used to specify job-processing options.

### Syntax

```
DBMS_DATAPUMP.SET_PARAMETER (
    handle      IN NUMBER,
    name        IN VARCHAR2,

### Parameters

**Table 50-24 SET\_PARAMETER Procedure Parameters**

| Parameter | Description                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| handle    | The handle of a job. The current session must have previously attached to the handle through a call to the <code>OPEN</code> function. |
| name      | The name of the parameter. <a href="#">Table 50-25</a> describes the valid parameter names.                                            |
| value     | The value for the specified parameter                                                                                                  |

[Table 50-25](#) describes the valid options for the `name` parameter of the `SET_PARAMETER` procedure.

**Table 50-25 Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name        | Datatype | Supported Operations | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLIENT_COMMAND        | TEXT     | All                  | An opaque string used to describe the current operation from the client's perspective. The command-line procedures will use this string to store the original command used to invoke the job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| COMPRESSION           | TEXT     | Export               | <p>Allows you to trade off the size of the dump file set versus the time it takes to perform export and import operations.</p> <p>The DATA_ONLY option compresses only user data in the dump file set.</p> <p>The METADATA_ONLY option compresses only metadata in the dump file set.</p> <p>The ALL option compresses both user data and metadata.</p> <p>The NONE option stores the dump file set in an uncompressed format.</p> <p>The METADATA_ONLY and NONE options require a job version of 10.2 or later. All other options require a job version of 11.1 or later.</p> <p>Default=METADATA_ONLY</p>                                                                                                                                                                                                                                                                                                                                          |
| COMPRESSION_ALGORITHM | TEXT     | Export               | <p>Indicates the compression algorithm is to be used when compressing dump file data. The choices are as follows:</p> <ul style="list-style-type: none"> <li>BASIC--Offers a good combination of compression ratios and speed; the algorithm used is the same as in previous versions of Oracle Data Pump.</li> <li>LOW---Least impact on backup throughput and suited for environments where CPU resources are the limiting factor.</li> <li>MEDIUM---Recommended for most environments. This option, like the BASIC option, provides a good combination of compression ratios and speed, but it uses a different algorithm than BASIC.</li> <li>HIGH--Best suited for exports over slower networks where the limiting factor is network speed.</li> </ul> <p>To use this feature, the COMPATIBLE initialization parameter must be set to at least 12.0.0.</p> <p>This feature requires that the Oracle Advanced Compression option be enabled.</p> |
| DATA_ACCESS_METHOD    | TEXT     | Export and Import    | Allows you to specify an alternative method to unload data if the default method does not work for some reason. The choices are AUTOMATIC, DIRECT_PATH, or EXTERNAL_TABLE. Oracle recommends that you use the default option (AUTOMATIC) whenever possible because it allows Data Pump to automatically select the most efficient method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 50-25 (Cont.) Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name | Datatype | Supported Operations | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|----------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA_OPTIONS   | Number   | Export and Import    | <p>A bitmask to supply special options for processing the job. The possible values are as follows:</p> <ul style="list-style-type: none"> <li>KU\$_DATAOPT_SKIP_CONST_ERR</li> <li>KU\$_DATAOPT_XMLTYPE_CLOB</li> <li>KU\$_DATAOPT_DISABL_APPEND_HINT</li> <li>KU\$_DATAOPT_GRP_PART_TAB</li> <li>KU\$_DATAOPT_TRUST_EXIST_TB_PAR</li> <li>KU\$_DATAOPT_CONT_LOAD_ON_FMT_ERR</li> </ul> <p>Export supports the value KU\$_DATAOPT_XMLTYPE_CLOB. This option stores compressed XMLType columns in the dump file in CLOB format rather than as XML documents.</p> <p><b>Note:</b> XMLType stored as CLOB is deprecated as of Oracle Database 12c Release 1 (12.1).</p> <p>Import supports the value KU\$_DATAOPT_SKIP_CONST_ERR. This option specifies that if constraint violations occur while data is being imported into user tables, the rows that cause the violations will be rejected and the load will continue. If this option is not set, a constraint error will abort the loading of the entire partition (or table for unpartitioned tables). Setting this option may affect performance, especially for pre-existing tables with unique indexes or constraints.</p> <p>Import also supports the value KU\$_DATAOPT_DISABL_APPEND_HINT. This option prevents the append hint from being applied to the data load. Disabling the APPEND hint can be useful if there is a small set of data objects to load that already exist in the database and some other application may be concurrently accessing one or more of the data objects.</p> <p>Data Pump Export supports the value KU\$_DATAOPT_GRP_PART_TAB. This option tells Data Pump to unload all table data in one operation rather than unload each table partition as a separate operation. As a result, the definition of the table will not matter at import time because Import will see one partition of data that will be loaded into the entire table.</p> <p>Data Pump Import supports the value KU\$_DATAOPT_TRUST_EXIST_TB_PAR. This option tells Data Pump to load partition data in parallel into existing tables.</p> <p>Use of the DATA_OPTIONS parameter requires that the version on the OPEN function be set to 11.1 or later.</p> <p>Default=0</p> <p>Data Pump Import supports the value KU\$_DATAOPT_CONT_LOAD_ON_FMT_ERR. This option tells Data Pump to skip forward to the start of the next granule if a stream format error is encountered while loading table data. Most stream format errors are caused by corrupt dump files. This value can be used if Data Pump encounters a stream format error and the original export database is not available to export the table data again. If Data Pump skips over data, not all data from the source database is imported potentially skipping hundreds or thousands of rows.</p> |

**Table 50-25 (Cont.) Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name       | Datatype | Supported Operations | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|----------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENCRYPTION           | TEXT     | Export               | <p>Specifies what to encrypt in the dump file set, as follows:</p> <p><b>ALL</b> enables encryption for all data and metadata in the export operation.</p> <p><b>DATA_ONLY</b> specifies that only data is written to the dump file set in encrypted format.</p> <p><b>ENCRYPTED_COLUMNS_ONLY</b> specifies that only encrypted columns are written to the dump file set in encrypted format.</p> <p><b>METADATA_ONLY</b> specifies that only metadata is written to the dump file set in encrypted format.</p> <p><b>NONE</b> specifies that no data is written to the dump file set in encrypted format.</p> <p>This parameter requires a job version of 11.1 or later.</p> <p>The default value depends upon the combination of encryption-related parameters that are used. To enable encryption, either <b>ENCRYPTION</b> or <b>ENCRYPTION_PASSWORD</b> or both, must be specified. If only <b>ENCRYPTION_PASSWORD</b> is specified, then <b>ENCRYPTION</b> defaults to <b>ALL</b>. If neither <b>ENCRYPTION</b> nor <b>ENCRYPTION_PASSWORD</b> is specified, then <b>ENCRYPTION</b> defaults to <b>NONE</b>.</p> <p>To specify <b>ALL</b>, <b>DATA_ONLY</b>, or <b>METADATA_ONLY</b>, the <b>COMPATIBLE</b> initialization parameter must be set to at least 11.1.</p> <p><b>NOTE:</b> If the data being exported includes SecureFiles that you want to be encrypted, then you must specify <b>ENCRYPTION=ALL</b> to encrypt the entire dump file set. Encryption of the entire dump file set is the only way to achieve encryption security for SecureFiles during a Data Pump export operation.</p> |
| ENCRYPTION_ALGORITHM | TEXT     | Export               | <p>Identifies which cryptographic algorithm should be used to perform encryption. Possible values are <b>AES128</b>, <b>AES192</b>, and <b>AES256</b>.</p> <p>The <b>ENCRYPTION_ALGORITHM</b> parameter requires that you also specify either <b>ENCRYPTION</b> or <b>ENCRYPTION_PASSWORD</b>; otherwise an error is returned. See <i>Oracle Database Advanced Security Guide</i> for information about encryption algorithms.</p> <p>This parameter requires a job version of 11.1 or later.</p> <p>Default=AES128</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 50-25 (Cont.) Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name      | Datatype | Supported Operations | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|----------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENCRYPTION_MODE     | TEXT     | Export               | <p>Identifies the types of security used for encryption and decryption. The values are as follows:</p> <p><b>PASSWORD</b> requires that you provide a password when creating encrypted dump file sets. You will need to provide the same password when you import the dump file set. <b>PASSWORD</b> mode requires that you also specify the <b>ENCRYPTION_PASSWORD</b> parameter. The <b>PASSWORD</b> mode is best suited for cases in which the dump file set will be imported into a different or remote database, but which must remain secure in transit.</p> <p><b>TRANSPARENT</b> allows an encrypted dump file set to be created without any intervention from a database administrator (DBA), provided the required Oracle Encryption Wallet is available. Therefore, the <b>ENCRYPTION_PASSWORD</b> parameter is not required, and will in fact, cause an error if it is used in <b>TRANSPARENT</b> mode. This encryption mode is best suited for cases in which the dump file set will be imported into the same database from which it was exported.</p> <p><b>DUAL</b> creates a dump file set that can later be imported using either the Oracle Encryption Wallet or the password that was specified with the <b>ENCRYPTION_PASSWORD</b> parameter. <b>DUAL</b> mode is best suited for cases in which the dump file set will be imported on-site using the Oracle Encryption Wallet, but which may also need to be imported offsite where the Oracle Encryption Wallet is not available.</p> <p>When you use the <b>ENCRYPTION_MODE</b> parameter, you must also use either the <b>ENCRYPTION</b> or <b>ENCRYPTION_PASSWORD</b> parameter. Otherwise, an error is returned.</p> <p>To use <b>DUAL</b> or <b>TRANSPARENT</b> mode, the <b>COMPATIBLE</b> initialization parameter must be set to at least 11.1.</p> <p>The default mode depends on which other encryption-related parameters are used. If only <b>ENCRYPTION</b> is specified, then the default mode is <b>TRANSPARENT</b>. If <b>ENCRYPTION_PASSWORD</b> is specified and the Oracle Encryption Wallet is open, then the default is <b>DUAL</b>. If <b>ENCRYPTION_PASSWORD</b> is specified and the Oracle Encryption Wallet is closed, then the default is <b>PASSWORD</b>.</p> |
| ENCRYPTION_PASSWORD | TEXT     | Export and Import    | <p>For export operations, this parameter is required if <b>ENCRYPTION_MODE</b> is set to either <b>PASSWORD</b> or <b>DUAL</b>. It is also required for transportable export/import operations (job mode=FULL and TRANSPORTABLE=ALWAYS) when the database includes either encrypted tablespaces or tables with encrypted columns.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ESTIMATE            | TEXT     | Export and Import    | <p>Specifies that the estimate method for the size of the tables should be performed before starting the job.</p> <p>If <b>BLOCKS</b>, a size estimate for the user tables is calculated using the count of blocks allocated to the user tables.</p> <p>If <b>STATISTICS</b>, a size estimate for the user tables is calculated using the statistics associated with each table. If no statistics are available for a table, the size of the table is estimated using <b>BLOCKS</b>.</p> <p>The <b>ESTIMATE</b> parameter cannot be used in Transportable Tablespace mode.</p> <p>Default=BLOCKS</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 50-25 (Cont.) Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name   | Datatype | Supported Operations      | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ESTIMATE_ONLY    | NUMBER   | Export                    | Specifies that only the estimation portion of an export job should be performed. This option is useful for estimating the size of dump files when the size of the export is unknown.                                                                                                                                                                                                                                                                       |
| FLASHBACK_SCN    | NUMBER   | Export and network Import | System change number (SCN) to serve as transactionally consistent point for reading user data. If neither FLASHBACK_SCN nor FLASHBACK_TIME is specified, there will be no transactional consistency between partitions, except for logical standby databases and Streams targets. FLASHBACK_SCN is not supported in Transportable mode.<br><br>For FLASHBACK_SCN, Data Pump supports the new 8-byte big SCNs used in Oracle Database 12c release 2 (12.2). |
| FLASHBACK_TIME   | TEXT     | Export and network Import | Either the date and time used to determine a consistent point for reading user data or a string of the form TO_TIMESTAMP (...).<br><br>If neither FLASHBACK_SCN nor FLASHBACK_TIME is specified, there will be no transactional consistency between partitions.<br><br>FLASHBACK_SCN and FLASHBACK_TIME cannot both be specified for the same job. FLASHBACK_TIME is not supported in Transportable mode.                                                  |
| INCLUDE_METADATA | NUMBER   | Export and Import         | If nonzero, metadata for objects will be moved in addition to user table data.<br><br>If zero, metadata for objects will not moved. This parameter converts an Export operation into an unload of user data and an Import operation into a load of user data.<br><br>INCLUDE_METADATA is not supported in Transportable mode.<br><br>Default=1                                                                                                             |
| KEEP_MASTER      | NUMBER   | Export and Import         | Specifies whether the master table should be deleted or retained at the end of a Data Pump job that completes successfully. The master table is automatically retained for jobs that do not complete successfully.<br><br>Default=0.                                                                                                                                                                                                                       |
| LOGTIME          | TEXT     | Export and Import         | Specifies that messages displayed during export and import operations be timestamped. Valid options are as follows: <ul style="list-style-type: none"> <li>NONE--No timestamps on status or log file messages (this is the default)</li> <li>STATUS--Timestamps on status messages only</li> <li>LOGFILE--Timestamps on log file messages only</li> <li>ALL--Timestamps on both status and log file messages</li> </ul>                                    |
| MASTER_ONLY      | NUMBER   | Import                    | Indicates whether to import just the master table and then stop the job so that the contents of the master table can be examined.<br><br>Default=0.                                                                                                                                                                                                                                                                                                        |
| METRICS          | NUMBER   | Export and Import         | Indicates whether additional information about the job should be reported to the Data Pump log file.<br><br>Default=0.                                                                                                                                                                                                                                                                                                                                     |

**Table 50-25 (Cont.) Valid Options for the name Parameter in the SET\_PARAMETER Procedure**

| Parameter Name        | Datatype | Supported Operations      | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PARTITION_OPTIONS     | TEXT     | Import                    | <p>Specifies how partitioned tables should be handled during an import operation. The options are as follows:</p> <p>NONE means that partitioning is reproduced on the target database as it existed in the source database.</p> <p>DEPARTITION means that each partition or subpartition that contains storage in the job is reproduced as a separate unpartitioned table. Intermediate partitions that are subpartitioned are not re-created (although their subpartitions are converted into tables). The names of the resulting tables are system-generated from the original table names and partition names unless the name is overridden by the REMAP_TABLE metadata transform.</p> <p>MERGE means that each partitioned table is re-created in the target database as an unpartitioned table. The data from all of the source partitions is merged into a single storage segment. This option is not supported for transportable jobs or when the TRANSPORTABLE parameter is set to ALWAYS.</p> <p>This parameter requires a job version of 11.1 or later.</p> <p>Default=NONE</p> |
| REUSE_DATAFILES       | NUMBER   | Import                    | <p>Specifies whether the import job should reuse existing data files for tablespace creation.</p> <p>Default=0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| TABLESPACE_DATAFILE | TEXT     | Import                                          | <p>Specifies the full file specification for a data file in the transportable tablespace set. TABLESPACE_DATAFILE is only valid for transportable mode imports.</p> <p>TABLESPACE_DATAFILE can be specified multiple times, but the value specified for each occurrence must be different.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TARGET_EDITION      | TEXT     | Import                                          | <p>The application edition that will be used for determining where the objects will be loaded for import and for network import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TRANSPORTABLE       | TEXT     | Export (and network import or full-mode import) | <p>This option is for export operations done in table mode, and also for full-mode imports and network imports. It allows the data to be moved using transportable tablespaces.</p> <p>In table-mode storage segments in the moved tablespaces that are not associated with the parent schemas (tables) will be reclaimed at import time. If individual partitions are selected in a table-mode job, only the tablespaces referenced by those partitions will be moved. During import, the moved partitions can only be reconstituted as tables by using the PARTITION_OPTIONS=DEPARTITION parameter.</p> <p>Use of the TRANSPORTABLE parameter prohibits the subsequent import of the dump file into a database at a lower version or using different character sets. Additionally, the data files may need to be converted if the target database is on a different platform.</p> <p>In table-mode, the TRANSPORTABLE parameter is not allowed if a network link is supplied on the OPEN call.</p> <p>The possible values for this parameter are as follows:</p> <p>ALWAYS - data is always moved by moving data files. This option is valid only for table mode and full mode.</p> <p>NEVER - data files are never used for copying user data</p> <p>This parameter requires a job version of 11.1 or later</p> <p>This parameter requires a job version of 12.1 or later when the job mode is FULL.</p> <p>Default=NEVER</p> |
| TTS_FULL_CHECK      | NUMBER   | Export                                          | <p>If nonzero, verifies that a transportable tablespace set has no dependencies (specifically, IN pointers) on objects outside the set, and vice versa. Only valid for Transportable mode Exports.</p> <p>Default=0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| USER_METADATA       | NUMBER   | Export and network Import                       | <p>For schema-mode operations, specifies that the metadata to recreate the users' schemas (for example, privilege grants to the exported schemas) should also be part of the operation if set to nonzero. Users must be privileged to explicitly set this parameter.</p> <p>The USER_METADATA parameter cannot be used in Table, Tablespace, or Transportable Tablespace mode.</p> <p>Default=1 if user has DATAPUMP_EXP_FULL_DATABASE role; 0 otherwise.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

#### Exceptions

- INVALID\_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID\_ARGVAL. This exception could be due to any of the following causes:
  - An invalid name was supplied for an input parameter

- The wrong datatype was used for `value`
- A `value` was not supplied
- The supplied `value` was not allowed for the specified parameter name
- A flashback parameter had been established after a different flashback parameter had already been established
- A parameter was specified that did not support duplicate definitions
- `INVALID_OPERATION`. The operation specified is invalid in this context.
- `INVALID_STATE`. The specified job is not in the Defining state.
- `INCONSISTENT_ARGS`. Either the specified parameter is not supported for the current operation type or it is not supported for the current mode.
- `PRIVILEGE_ERROR`. The user does not have the `DATAPUMP_EXP_FULL_DATABASE` or `DATAPUMP_IMP_FULL_DATABASE` role required for the specified parameter.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

#### Usage Notes

- The `SET_PARAMETER` procedure is used to specify optional features for the current job. See [Table 50-25](#) for a list of supported options.

## 50.5.15 START\_JOB Procedure

This procedure begins or resumes job execution.

#### Syntax

```
DBMS_DATAPUMP.START_JOB (
    handle          IN NUMBER,
    skip_current    IN  NUMBER DEFAULT 0,
    abort_step      IN  NUMBER DEFAULT 0,
    cluster_ok      IN  NUMBER DEFAULT 1,
    service_name    IN  VARCHAR2 DEFAULT NULL);
```

#### Parameters

**Table 50-26 START\_JOB Procedure Parameters**

| Parameter           | Description                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>handle</code> | The handle of a job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function. |

**Table 50-26 (Cont.) START\_JOB Procedure Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>skip_current</code> | <p>If nonzero, causes actions that were 'in progress' on a previous execution of the job to be skipped when the job restarts. The skip will only be honored for Import jobs. This mechanism allows the user to skip actions that trigger fatal bugs and cause the premature termination of a job. Multiple actions can be skipped on a restart. The log file will identify which actions are skipped. If a domain index was being processed, all pieces of the domain index are skipped even if the error occurred in only a subcomponent of the domain index.</p> <p>A description of the actions skipped is entered into the log file. <code>skip_current</code> is ignored for the initial <code>START_JOB</code> in a job.</p> <p>If zero, no data or metadata is lost upon a restart.</p> |
| <code>abort_step</code>   | Value must be 0. Inserting values other than 0 into this argument will have unintended consequences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>cluster_ok</code>   | If = 0, all workers are started on the current instance. Otherwise, workers are started on instances usable by the job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>service_name</code> | If specified, indicates a service name used to constrain the job to specific instances or to a specific resource group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID_STATE`. The causes of this exception can be any of the following:
  - No files have been defined for an Export, non-network Import, or `SQL_FILE` job
  - An `ADD_FILE` procedure has not been called to define the output for a `SQL_FILE` job
  - A `TABLESPACE_DATAFILE` parameter has not been defined for a Transportable Import job
  - A `TABLESPACE_EXPR` metadata filter has not been defined for a Transportable or Tablespace mode Export or Network job
  - The dump file set on an Import or `SQL_FILE` job was either incomplete or missing a master table specification
- `INVALID_OPERATION`. Unable to restore master table from a dump file set.
- `INTERNAL_ERROR`. An inconsistency was detected when the job was started. Additional information may be available through the `GET_STATUS` procedure.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

### Usage Notes

- When this procedure is called to request that the corresponding job be started or restarted, the state of the job is changed from either the Defining or Idling state to the Executing state.
- If the `SET_PARALLEL` procedure was not called prior to the `START_JOB` procedure, the initial level of parallelism used in the job will be 1. If `SET_PARALLEL` was called prior to the job starting, the degree specified by the last `SET_PARALLEL` call determines the parallelism for

the job. On restarts, the parallelism is determined by the previous parallel setting for the job, unless it is overridden by another `SET_PARALLEL` call.

- To restart a stopped job, an `ATTACH` function must be performed prior to executing the `START_JOB` procedure.

## 50.5.16 STOP\_JOB Procedure

This procedure terminates a job, but optionally, preserves the state of the job.

### Syntax

```
DBMS_DATAPUMP.STOP_JOB (
    handle      IN NUMBER,
    immediate   IN NUMBER DEFAULT 0,
    keep_master IN NUMBER DEFAULT NULL,
    delay       IN NUMBER DEFAULT 60);
```

### Parameters

**Table 50-27 STOP\_JOB Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle      | The handle of a job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function. At the end of the procedure, the user is detached from the handle.                                                                                                                                                                                                                                                             |
| immediate   | If nonzero, the worker processes are aborted immediately. This halts the job quickly, but parts of the job will have to be rerun if the job is ever restarted.<br><br>If zero, the worker processes are allowed to complete their current work item (either metadata or table data) before they are terminated. The job is placed in a Stop Pending state while the workers finish their current work.                                                                                              |
| keep_master | If nonzero, the master table is retained when the job is stopped. If zero, the master table is dropped when the job is stopped. If the master table is dropped, the job will not be restartable. If the master table is dropped during an export job, the created dump files are deleted.                                                                                                                                                                                                           |
| delay       | The number of seconds to wait until other attached sessions are forcibly detached. The delay allows other sessions attached to the job to be notified that a stop has been performed. The job keeps running until either all clients have detached or the delay has been satisfied. If no delay is specified, then the default delay is 60 seconds. If a shorter delay is used, clients might not be able to retrieve the final messages for the job through the <code>GET_STATUS</code> procedure. |

### Exceptions

- `INVALID_HANDLE`. The specified handle is not attached to a Data Pump job.
- `INVALID STATE`. The job is already in the process of being stopped or completed.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

### Usage Notes

- This procedure is used to request that the corresponding job stop executing.

- The termination of a job that is in an Executing state may take several minutes to complete in an orderly fashion.
- For jobs in the Defining, Idling, or Completing states, this procedure is functionally equivalent to the `DETACH` procedure.
- Once a job is stopped, it can be restarted using the `ATTACH` function and `START_JOB` procedures, provided the master table and the dump file set are left intact.
- If the `KEEP_MASTER` parameter is not specified, and the job is in the Defining state or has a mode of Transportable, the master table is dropped. Otherwise, the master table is retained.

## 50.5.17 WAIT\_FOR\_JOB Procedure

This procedure runs a job until it either completes normally or stops for some other reason.

### Syntax

```
DBMS_DATAPUMP.WAIT_FOR_JOB (  
    handle      IN    NUMBER,  
    job_state   OUT   VARCHAR2);
```

### Parameters

**Table 50-28** WAIT\_FOR\_JOB Procedure Parameters

| Parameter | Description                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handle    | The handle of the job. The current session must have previously attached to the handle through a call to either the <code>OPEN</code> or <code>ATTACH</code> function. At the end of the procedure, the user is detached from the handle. |
| job_state | The state of the job when it has stopped executing; either <code>STOPPED</code> or <code>COMPLETED</code> .                                                                                                                               |

### Exceptions

- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` API.
- `INVALID_HANDLE`. The job handle is no longer valid.

### Usage Notes

This procedure provides the simplest mechanism for waiting for the completion of a Data Pump job. The job should be started before calling `WAIT_FOR_JOB`. When `WAIT_FOR_JOB` returns, the job will no longer be executing. If the job completed normally, the final status will be `COMPLETED`. If the job stopped executing because of a `STOP_JOB` request or an internal error, the final status will be `STOPPED`.

# 51

## DBMS\_DB\_VERSION

The `DBMS_DB_VERSION` package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

### See Also:

*Oracle Database PL/SQL Language Reference* regarding conditional compilation

This package contains the following topics:

- [Overview](#)
- [Constants](#)
- [Examples](#)

### 51.1 DBMS\_DB\_VERSION Overview

The `DBMS_DB_VERSION` package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

The package for the Oracle Database 19c version is shown below.

```
PACKAGE DBMS_DB_VERSION IS
  VERSION CONSTANT PLS_INTEGER := 19; -- RDBMS version number
  RELEASE CONSTANT PLS_INTEGER := 0; -- RDBMS release number
  ver_le_9_1      CONSTANT BOOLEAN := FALSE;
  ver_le_9_2      CONSTANT BOOLEAN := FALSE;
  ver_le_9        CONSTANT BOOLEAN := FALSE;
  ver_le_10_1     CONSTANT BOOLEAN := FALSE;
  ver_le_10_2     CONSTANT BOOLEAN := FALSE;
  ver_le_10       CONSTANT BOOLEAN := FALSE;
  ver_le_11_1     CONSTANT BOOLEAN := FALSE;
  ver_le_11_2     CONSTANT BOOLEAN := FALSE;
  ver_le_11       CONSTANT BOOLEAN := FALSE;
  ver_le_12_1     CONSTANT BOOLEAN := FALSE;
  ver_le_12_2     CONSTANT BOOLEAN := FALSE;
  ver_le_12       CONSTANT BOOLEAN := FALSE;
  ver_le_18       CONSTANT BOOLEAN := FALSE;
  ver_le_19       CONSTANT BOOLEAN := TRUE;
END DBMS_DB_VERSION;
```

The boolean constants follow a naming convention. Each constant gives a name for a boolean expression. For example:

- `VER_LE_9_1` represents version  $\leq 9$  and release  $\leq 1$
- `VER_LE_10_2` represents version  $\leq 10$  and release  $\leq 2$
- `VER_LE_10` represents version  $\leq 10$

A typical usage of these boolean constants is:

```
$IF DBMS_DB_VERSION.VER_LE_10 $THEN
    version 10 and earlier code
$ELSIF DBMS_DB_VERSION.VER_LE_11 $THEN
    version 11 code
$ELSE
    version 12 and later code
$END
```

This code structure will protect any reference to the code for version 12. It also prevents the controlling package constant `DBMS_DB_VERSION.VER_LE_11` from being referenced when the program is compiled under version 10. A similar observation applies to version 11. This scheme works even though the static constant `VER_LE_11` is not defined in version 10 database because conditional compilation protects the `$ELSIF` from evaluation if

`DBMS_DB_VERSION.VER_LE_10` is TRUE.

## 51.2 DBMS\_DB\_VERSION Constants

The `DBMS_DB_VERSION` package contains different constants for different Oracle Database releases.

The Oracle Database 19c version of the `DBMS_DB_VERSION` package uses the constants shown in the following table.

**Table 51-1 DBMS\_DB\_VERSION Constants**

| Name        | Type        | Value | Description                    |
|-------------|-------------|-------|--------------------------------|
| VERSION     | PLS_INTEGER | 19    | Current version                |
| RELEASE     | PLS_INTEGER | 0     | Current release                |
| VER_LE_9    | BOOLEAN     | FALSE | Version <= 9                   |
| VER_LE_9_1  | BOOLEAN     | FALSE | Version <= 9 and release <= 1  |
| VER_LE_9_2  | BOOLEAN     | FALSE | Version <= 9 and release <= 2  |
| VER_LE_10   | BOOLEAN     | FALSE | Version <= 10                  |
| VER_LE_10_1 | BOOLEAN     | FALSE | Version <= 10 and release <= 1 |
| VER_LE_10_2 | BOOLEAN     | FALSE | Version <=10 and release <= 2  |
| VER_LE_11   | BOOLEAN     | FALSE | Version <= 11                  |
| VER_LE_11_1 | BOOLEAN     | FALSE | Version <=11 and release <= 1  |
| VER_LE_11_2 | BOOLEAN     | FALSE | Version <=11 and release <= 2  |
| VER_LE_12   | BOOLEAN     | FALSE | Version <=12                   |
| VER_LE_12_1 | BOOLEAN     | FALSE | Version <=12 and release <= 1  |
| VER_LE_12_2 | BOOLEAN     | FALSE | Version <=12 and release <= 2  |
| VER_LE_18   | BOOLEAN     | FALSE | Version <=18                   |
| VER_LE_19   | BOOLEAN     | TRUE  | Version <=19                   |

## 51.3 DBMS\_DB\_VERSION Examples

This example uses conditional compilation to guard new features.

```
CREATE OR REPLACE PROCEDURE whetstone IS

  -- Notice that conditional compilation constructs
  -- can interrupt a regular PL/SQL statement.
  -- You can locate a conditional compilation directive anywhere
  -- there is whitespace in the regular statement.

  SUBTYPE my_real IS
    $IF DBMS_DB_VERSION.VER_LE_9 $THEN NUMBER
                                $ELSE BINARY_DOUBLE
    $END;

  t  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 0.499975
                                $ELSE 0.499975d
    $END;

  t2 CONSTANT my_real := $if DBMS_DB_VERSION.VER_LE_9 $THEN 2.0
                                $ELSE 2.0d
    $END;

  x  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 1.0
                                $ELSE 1.0d
    $END;

  y  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 1.0
                                $ELSE 1.0d
    $END;

  z  MY_REAL;

  PROCEDURE P(x IN my_real, y IN my_real, z OUT NOCOPY my_real) IS
    x1 my_real;
    y1 my_real;
  BEGIN
    x1 := x;
    y1 := y;
    x1 := t * (x1 + y1);
    y1 := t * (x1 + y1);
    z := (x1 + y1)/t2;
  END P;

  BEGIN
    P(x, y, z);
    DBMS_OUTPUT.PUT_LINE ('z = ' || z);
  END whetstone;
/
```

## DBMS\_DBCOMP

The `DBMS_DBCOMP` package performs block comparison to detect lost writes or database inconsistencies between a primary database and one or more physical standby databases. It contains one procedure, `DBCMP`, which can be executed at any time. (It does not require that the `DB_LOST_WRITE_PROTECT` initialization parameter be enabled.)

This chapter contains the following sections:

- [Using DBMS\\_DBCOMP](#)
- [DBMS\\_DBCOMP Security Model](#)
- [DBCMP Procedure](#)

### Related Topics

- [Oracle Data Guard Concepts and Administration](#)

## 52.1 Using DBMS\_DBCOMP

The `DBMS_DBCOMP.DBCMP` procedure assumes that there is one primary database and one or more physical standby databases. The databases should be at least mounted before block comparison.

### Note:

Logical standby databases, far sync instances, and cascaded standbys cannot be the target database for the `DBMS_DBCOMP.DBCMP` procedure.

While this procedure is running, you can monitor progress of the compare operation by querying the `V$SESSION_LONGOPS` view. For example:

```
SQL> SELECT target_desc, sofar, totalwork FROM V$SESSION_LONGOPS WHERE opname
= 'BlockCompare';
```

The output might look as follows:

| TARGET_DESC     | SO FAR | TOTALWORK |
|-----------------|--------|-----------|
| -----           | -----  | -----     |
| Compared Blocks | 23914  | 340639    |
| Lost Writes     | 0      | 0         |

The results can be interpreted as follows:

- The `Compared Blocks` value is the number of blocks that were scanned (including those that did not use compare callback functions). The number is the sum of all slaves (that is, each slave is responsible for a connection between primary and standby). For example, if

there are two slaves and each slave has compared 1000 blocks, then the value of `SOFAR` should be 2000.

- The `Lost Writes` value is the number of lost writes found at both the primary and the standby. Also, it is the sum of all slaves. For `Lost Writes`, the value of `SOFAR` should be always equal to the value of `TOTALWORK`.
- The value of `SOFAR` should be always less than or equal to the value of `TOTALWORK`.
- When the block compare slave processes finish, the value of `SOFAR` should be equal to the value of `TOTALWORK`.

## 52.2 DBMS\_DBCOMP Security Model

The `DBMS_DBCOMP` package runs with invoker's rights and requires the `SYSDBA` or `SYSDG` or `SYSBACKUP` privilege.

## 52.3 Summary of the DBMS\_DBCOMP Subprogram

The `DBMS_DBCOMP` package contains one procedure, `DBCOMP`.

| Subprogram                    | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DBCOMP</code> procedure | The <code>DBMS_DBCOMP.DBCOMP</code> procedure performs block comparison to detect lost writes or database inconsistencies between a primary database and one or more physical standby databases. The <code>DBCOMP</code> procedure can be executed on the primary or on the physical standby while the databases are mounted or open. |

### 52.3.1 DBCOMP Procedure

Use `DBCOMP` procedure to compare blocks on a primary database and one or more physical standby databases.

#### Syntax

```
DBMS_DBCOMP.DBCOMP (  
    datafile IN varchar2,  
    outputfile IN varchar2,  
    block_dump IN boolean);
```

#### Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>datafile</code>   | This can be a data file name or a data file number. Specify <code>'ALL'</code> to compare all data files.                                                                                                                                                                                                                  |
| <code>outputfile</code> | This value is used as a prefix in the name of the output file. By default, output files are placed in the <code>dbs/</code> directory, but the output file argument can contain a relative directory path or an absolute directory path. See Usage Notes for descriptions of the information contained in the output file. |

| Parameter  | Description                                                                                                                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| block_dump | This is a Boolean parameter to specify whether block content should be dumped into output files if a pair of blocks of primary and standby databases is not identical. This parameter does not guarantee that all different block pairs are dumped. The default value is <code>FALSE</code> . |

### Usage Notes

- The output file contains the following columns:
  - **ID**: The block type. For instance, type 02 is undo block type, and 06 is KTB-managed data block type.
  - **TOTAL**: The total number of blocks in the specific block type.
  - **CORR**: The number of corrupted blocks.
  - **SKIPPED**: The number of block pairs that are skipped (ignored) without comparison, such as direct loaded blocks, RMAN optimized blocks, and flashback optimized blocks.
  - **DIFFV**: The number of blocks that have different version numbers between primary and standby.
  - **SAMEV**: The number of block pairs that have the same version number between primary and standby.
  - **SAMEV&C**: The number of block pairs that have the same version and the same checksum.
  - **ENCERR**: The number of block pairs that have encryption related errors (usually because the Wallet is not open).
  - **LWLOC**: The number of lost writes on the local database.
  - **LWRMT**: The number of lost writes on the remote databases.
  - **DIFFPAIR** : The number of block pairs that have the same version but different checksum, and which the block compare callback function has concluded are different.

### Example 52-1 Example

The following is an example of using the `DBMS_DBCOMP.DBCOMP` procedure.

```
declare
  Datafile_Name_or_Number varchar2(1000);
  Output_File varchar2(1000);
begin
  dbms_output.enable(1000000);
  Datafile_Name_or_Number:= 'all' ;
  Output_File:='BlockCompareAll_';
  sys.dbms_dbcomp.DBCOMP(Datafile_Name_or_Number, Output_File, true);
end;
```

# DBMS\_DBFS\_CONTENT

The `DBMS_DBFS_CONTENT` package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

This chapter contains the following topics:

- [Overview](#)
- [Security Model](#)
- [Constants](#)
- [Exceptions](#)
- [Operational Notes](#)
- [Data Structures](#)
- [Summary of DBMS\\_DBFS\\_CONTENT Subprograms](#)

## See Also:

## 53.1 DBMS\_DBFS\_CONTENT Overview

The `DBMS_DBFS_CONTENT` package provides an interface that connects the Oracle database to the DBFS client-side.

In the server, the `DBMS_DBFS_CONTENT` package is backed by the `DBMS_DBFS_CONTENT_SPI` package, which includes descriptions but not actual implementations of DBFS stores.

## See Also:

- Oracle Database SecureFiles and Large Objects Developer's Guide for a description of `DBMS_DBFS_CONTENT` and the DBFS architecture
- Oracle Database SecureFiles and Large Objects Developer's Guide for conceptual information about the `DBMS_DBFS_CONTENT` package

## 53.2 DBMS\_DBFS\_CONTENT Security Model

The `DBMS_DBFS_CONTENT` package runs under `AUTHID CURRENT_USER`.

## 53.3 DBMS\_DBFS\_CONTENT Constants

The `DBMS_DBFS_CONTENT` package uses various types of constants.

These are shown in the following tables:

- [Table 53-1](#)
- [Table 53-2](#)
- [Table 53-3](#)
- [Table 53-4](#)
- [Table 53-5](#)
- [Table 53-6](#)
- [Table 53-7](#)
- [Table 53-8](#)
- [Table 53-9](#)
- [Table 53-10](#)

### Path Name Constants and Types

The following constants are useful for declaring paths and item names. Paths are limited to 1024 characters and item names are limited to 256 characters.

**Table 53-1 DBMS\_DBFS\_CONTENT Constants - Path Names**

| Constant              | Type                        | Value                 | Description                                                                            |
|-----------------------|-----------------------------|-----------------------|----------------------------------------------------------------------------------------|
| <code>NAME_MAX</code> | <code>PLS_INTEGER</code>    | 256                   | Maximum length of an absolute path name visible to clients                             |
| <code>NAME_T</code>   | <code>VARCHAR2(256)</code>  | <code>NAME_MAX</code> | Portable alias for string that can represent component names                           |
| <code>PATH_MAX</code> | <code>PLS_INTEGER</code>    | 1024                  | Maximum length of any individual component of an absolute path name visible to clients |
| <code>PATH_T</code>   | <code>VARCHAR2(1024)</code> | <code>PATH_MAX</code> | Portable alias for string that can represent path names                                |

### ContentID Constants

Stores may expose to the user a unique identifier that represents a particular path item in the store. These identifiers are limited to 128 characters.

**Table 53-2 DBMS\_DBFS\_CONTENT Constants - ContentID**

| Constant                    | Type                     | Value                       | Description                                                                                              |
|-----------------------------|--------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------|
| <code>CONTENT_ID_MAX</code> | <code>PLS_INTEGER</code> | 128                         | Maximum length of a store-specific provider-generated contentID that identifies a file-type content item |
| <code>CONTENT_ID_T</code>   | <code>RAW(128)</code>    | <code>CONTENT_ID_MAX</code> | Portable alias for raw buffers that can represent contentID values                                       |

### Path Properties Constants

Every path name in a store is associated with a set of properties. Each property is identified by a string "name", has a string "value" (which might be `NULL` if unset or undefined or unsupported by a specific store implementation) and a value "typecode" (a numeric discriminant for the actual type of value held in the "value" string.)

**Table 53-3 DBMS\_DBFS\_CONTENT Constants - Properties**

| Constant     | Type            | Value        | Description                                                  |
|--------------|-----------------|--------------|--------------------------------------------------------------|
| PROPNAME_MAX | PLS_INTEGER     | 32           | Maximum length of a property name                            |
| PROPNAME_T   | VARCHAR2 (32)   | PROPNAME_MAX | Portable alias for string that can represent property names  |
| PROPVAL_MAX  | PLS_INTEGER     | 1024         | Maximum length of the string value of a property             |
| PROPVAL_T    | VARCHAR2 (1024) | PATH_MAX     | Portable alias for string that can represent property values |

### Path Name Type Constants

Path items in a store have a item type associated with them. These types represent the kind of entry the item represents in the store.

**Table 53-4 DBMS\_DBFS\_CONTENT Constants - Path Name Types**

| Constant       | Type        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TYPE_FILE      | PLS_INTEGER | 1     | A regular file storing content (a logically linear sequence of bytes accessed as a BLOB)                                                                                                                                                                                                                                                                                                                                                    |
| TYPE_DIRECTORY | PLS_INTEGER | 2     | A container of other path name types, including file types                                                                                                                                                                                                                                                                                                                                                                                  |
| TYPE_LINK      | PLS_INTEGER | 3     | A symbolic link (that is, an uninterpreted string value associated with a path name). Since symbolic links may represent path names that fall outside the scope of any given store (or even the entire aggregation of stores managed by the DBMS_DBFS_CONTENT interface), or may not even represent path names, clients must be careful in creating symbolic links, and stores must be careful in trying to resolve these links internally. |
| TYPE_REFERENCE | PLS_INTEGER | 4     | A hard link which is always a valid path name alias to content                                                                                                                                                                                                                                                                                                                                                                              |
| TYPE_SOCKET    | PLS_INTEGER | 5     | UNIX domain socket created using socket interface defined as in <code>socket.h</code> with domain defined as <code>AF_UNIX</code> or <code>AF_LOCAL</code> .                                                                                                                                                                                                                                                                                |

## Store Feature Constants

The DBFS content API allows different store providers (and different stores) to describe themselves through a *feature set* (a bitmask indicating which features they support and which ones they do not).

**Table 53-5 DBMS\_DBFS\_CONTENT Constants - Store Features**

| Constant           | Type        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_FOLDERS    | PLS_INTEGER | 1     | Set if the store supports folders (or directories) as part of hierarchical path names                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| FEATURE_FOIAF      | PLS_INTEGER | 2     | Set if implicit folder operations within the store (performed as part of a client-requested operation) runs inside autonomous transactions. In general, the use of autonomous transactions is a compromise between (a) simplicity in the implementation and client-controlled transaction scope for all operations, at the cost of greatly reduced concurrency (FEATURE_FOIAF not set), versus (b) more complex implementation and smaller client-controlled transaction scope, at the benefit of greatly increased concurrency (FEATURE_FOIAF set). |
| FEATURE_NOWAIT     | PLS_INTEGER | 4     | Set if the store allows <code>nowait</code> gets of path elements. The default behavior is to wait for row locks; if <code>nowait</code> gets are implemented, the get operation raises an ORA-54 exception if the path element is already locked by another transaction.                                                                                                                                                                                                                                                                            |
| FEATURE_ACLS       | PLS_INTEGER | 8     | Set if the store supports Access Control Lists (ACLs) and internal authorization or checking based on these ACLs. ACLs are standard properties but a store may do nothing more than store and retrieve the ACLs without interpreting them in any way.                                                                                                                                                                                                                                                                                                |
| FEATURE_LINKS      | PLS_INTEGER | 16    | Set if the store supports symbolic links, and if certain types of symbolic links (specifically non-absolute path names) can be internally resolved by the store itself                                                                                                                                                                                                                                                                                                                                                                               |
| FEATURE_LINK_DEREF | PLS_INTEGER | 32    | Set if the store supports symbolic links, and if certain types of symbolic links (specifically non-absolute path names) can be internally resolved by the store itself                                                                                                                                                                                                                                                                                                                                                                               |
| FEATURE_REFERENCES | PLS_INTEGER | 64    | Set if the store supports hard links                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 53-5 (Cont.) DBMS\_DBFS\_CONTENT Constants - Store Features**

| Constant               | Type        | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|-------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_LOCKING        | PLS_INTEGER | 128   | Set if the store supports user-level locks (read-only, write-only, read-write) that can be applied on various items of the store, and if the store uses these lock settings to control various types of access to the locked items. User-level locks are orthogonal to transaction locks and persist beyond the scope of any specific transaction, session, or connection — this implies that the store itself may not be able to clean up after dangling locks, and client-applications need to perform any garbage collection. |
| FEATURE_LOCK_HIERARCHY | PLS_INTEGER | 256   | Set if the store allows a user-lock to control access to the entire sub-tree under the locked path name.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FEATURE_LOCK_CONVERT   | PLS_INTEGER | 512   | Set if the store supports upgrade or downgrade of locks from one mode to another                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| FEATURE_VERSIONING     | PLS_INTEGER | 1024  | Set if the store supports at least a linear versioning and version management. Different versions of the same path name are identified by monotonic version numbers, with a version-qualified path name representing the latest version.                                                                                                                                                                                                                                                                                         |
| FEATURE_VERSION_PATH   | PLS_INTEGER | 2048  | Set if the store supports a hierarchical namespace for different versions of a path name                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FEATURE_SOFT_DELETES   | PLS_INTEGER | 4096  | Set if the store supports a "soft-delete", that is, the ability to delete a path name and make it invisible to normal operations, but retain the ability to restore the path name later (as long as it has not been overwritten by a new create operation). The store also supports purging soft-deleted path names (making them truly deleted), and navigation modes that show soft-deleted items.                                                                                                                              |
| FEATURE_HASHING        | PLS_INTEGER | 8192  | Set if the store automatically computes and maintains some type of a secure hash of the contents of a path name (typically a TYPE_FILE path).                                                                                                                                                                                                                                                                                                                                                                                    |
| FEATURE_HASH_LOOKUP    | PLS_INTEGER | 16384 | Set if the store allows "content-based addressing", that is, the ability to locate a content item based, not on its path name, but on its content hash.                                                                                                                                                                                                                                                                                                                                                                          |

Table 53-5 (Cont.) DBMS\_DBFS\_CONTENT Constants - Store Features

| Constant          | Type        | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|-------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_FILTERING | PLS_INTEGER | 32768  | <p>Set if the store allows clients to pass a filter function (a PL/SQL function conforming to the signature below) that returns a logical boolean indicating if a given store item satisfies a selection predicate. Stores that support filtering may be able to more efficiently perform item listing, directory navigation, and deletions by embedding the filtering logic inside their implementation. If filtering is not supported, clients can retrieve more items than necessary and perform the filtering checks themselves, albeit less efficiently.</p> <p>A filter predicate is a function with the following signature:</p> <pre>function filterFunction(   path          IN   VARCHAR2,   store_name    IN   VARCHAR2,   opcode        IN   INTEGER,   item_type     IN   INTEGER,   properties    IN DBMS_DBFS_CONTENT_PROPERTIES_T,   content       IN   BLOB)   RETURN INTEGER;</pre> <p>Any PL/SQL function conforming to this signature can examine the contents and properties of a store item, and determine if the item satisfies the selection criterion for the current operation. Any nonzero return value results in the DBMS_DBFS_CONTENT interface processing the item as part of the current operation; a return value that is zero or NULL results in the item being skipped from processing.</p> |
| FEATURE_SEARCHING | PLS_INTEGER | 65536  | <p>Set if the store allows clients to pass a text-search filter query to locate <code>type_file</code> path names based on their content. Stores that support searching may use indexes to accelerate such searches; otherwise, clients need to build their own indexes, or else search a potentially larger set of items to locate the ones of interest for the current search.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| FEATURE_ASOF      | PLS_INTEGER | 131072 | <p>Set if the store allows clients to use a flashback timestamp in query operations (non-mutating <a href="#">GETPATH Procedures</a> and <a href="#">LIST Function</a>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 53-5 (Cont.) DBMS\_DBFS\_CONTENT Constants - Store Features**

| Constant               | Type        | Value   | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_PROVIDER_PROPS | PLS_INTEGER | 262144  | Set if the store allows per-operation properties (that control the behavior of the store with regard to the current operation, as opposed to properties associated with individual items).                                                                                                                                                                                                    |
| FEATURE_SNAPSHOTS      | PLS_INTEGER | 524288  | Set if the store allows the use of named, read-only snapshots of its contents. It is up to the provider to implement snapshots using any suitable means (including creating immediate copies of the content, or using copy-on-write) and managing dependencies between snapshots and its parent content view.                                                                                 |
| FEATURE_CLONES         | PLS_INTEGER | 1048576 | Set if the store allows the use of named, writable clones of its contents. It is up to the provider to implement clones using any suitable means (including creating immediate copies of the content, or using copy-on-write) and managing dependencies between clones and its parent content view.                                                                                           |
| FEATURE_LOCATOR        | PLS_INTEGER | 2097152 | Set if the store allows direct access to file contents through a LOB locator. Stores that internally manipulate the file contents, perhaps by shredding or reassembling them in separate pieces, performing other transformations, and so on, cannot transparently give out a LOB locator to clients. The file contents of these stores should be accessed using the buffer-based interfaces. |
| FEATURE_CONTENT_ID     | PLS_INTEGER | 4194304 | Set if the store allows a "pathless", contentID-based access to files (there is no notion of a directory, link, or reference in this model)                                                                                                                                                                                                                                                   |
| FEATURE_LAZY_PATH      | PLS_INTEGER | 8388608 | Set if the store allows a lazy binding of a path name to file content elements that are otherwise identified by a contentID; this feature makes sense only in conjunction with FEATURE_CONTENT_ID                                                                                                                                                                                             |

**Lock Type Constants**

Stores that support locking should implement 3 types of locks: LOCK\_READ\_ONLY, LOCK\_WRITE\_ONLY, and LOCK\_READ\_WRITE.

**Table 53-6 DBMS\_DBFS\_CONTENT Constants - Lock Types**

| Constant       | Type        | Value | Description        |
|----------------|-------------|-------|--------------------|
| LOCK_READ_ONLY | PLS_INTEGER | 1     | Locks as read-only |

**Table 53-6 (Cont.) DBMS\_DBFS\_CONTENT Constants - Lock Types**

| Constant        | Type        | Value | Description         |
|-----------------|-------------|-------|---------------------|
| LOCK_WRITE_ONLY | PLS_INTEGER | 2     | Locks as write-only |
| LOCK_READ_WRITE | PLS_INTEGER | 3     | Locks as read-write |

**Standard Property Constants**

Standard properties are well-defined, mandatory properties associated with all content path names that all stores should support (in the manner described by the content interface), with some exceptions. For example, a read-only store need not implement a `modification_time` or `creation_time`.

All standard properties informally use the `STD` namespace, which clients and stores should avoid using.

**Table 53-7 DBMS\_DBFS\_CONTENT Constants - Standard Properties**

| Constant           | Type          | Value                | Description                                                                                                                                                                                            |
|--------------------|---------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STD_ACCESS_TIME    | VARCHAR2 (32) | 'std:access_time'    | TYPECODE_TIMESTAMP in UTC: The time of last access of a path name's contents                                                                                                                           |
| STD_ACL            | VARCHAR2 (32) | 'std:acl'            | TYPECODE_VARCHAR2: The access control list (in standard ACL syntax) associated with the path name                                                                                                      |
| STD_CANONICAL_PATH | VARCHAR2 (32) | 'std:canonical_path' | TYPECODE_VARCHAR2: The canonical store-specific path name of an item.                                                                                                                                  |
| STD_CHANGE_TIME    | VARCHAR2 (32) | 'std:change_time'    | TYPECODE_TIMESTAMP in UTC: The time of last change to the metadata of a path name                                                                                                                      |
| STD_CHILDREN       | VARCHAR2 (32) | 'std:children'       | TYPECODE_NUMBER: The number of child directories/folders a directory/folder path has (this property should be available in providers that support the FEATURE_FOLDERS feature)                         |
| STD_CONTENT_TYPE   | VARCHAR2 (32) | 'std:content_type'   | TYPECODE_NUMBER: The client-supplied mime-type(s) (in standard RFC syntax) describing the (typically <code>type_file</code> ) path name. The content type is not necessarily interpreted by the store. |
| STD_CREATION_TIME  | VARCHAR2 (32) | 'std:creation_time'  | TYPECODE_TIMESTAMP in UTC: The time at which the item was created (once set, this value never changes for the lifetime of the path name)                                                               |
| STD_DELETED        | VARCHAR2 (32) | 'std:deleted'        | TYPECODE_NUMBER as a BOOLEAN: Set to a nonzero number if the path name has been soft-deleted but not yet purged.                                                                                       |

Table 53-7 (Cont.) DBMS\_DBFS\_CONTENT Constants - Standard Properties

| Constant              | Type          | Value                   | Description                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|---------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STD_GUID              | VARCHAR2 (32) | 'std:guid'              | TYPECODE_NUMBER: A store-specific unique identifier for a path name. Clients must not depend on the GUID being unique across different stores, but a given ( <i>store-name</i> , <i>store-specific-path name</i> ) has a stable and unique GUID for its lifetime.                                                                                   |
| STD_LENGTH            | VARCHAR2 (32) | 'std:length'            | TYPECODE_NUMBER: The length of the content (BLOB) of a TYPE_FILE/TYPE_REFERENCE path, or the length of the referent of a TYPE_LINK symbolic link. Directories do not have a well-defined length and stores are free to set this property to zero, NULL, or any other value.                                                                         |
| STD_MODIFICATION_TIME | VARCHAR2 (32) | 'std:modification_time' | TYPECODE_TIMESTAMP in UTC: The time of last change to the data associated with a path name. Change to the content of a TYPE_FILE/TYPE_REFERENCE path, the referent of the TYPE_LINK path, and addition or deletion of immediate children in a TYPE_DIRECTORY path, all constitute data changes.                                                     |
| STD_OWNER             | VARCHAR2 (32) | 'std:owner'             | TYPECODE_VARCHAR2: A client-supplied (or implicit) owner name for the path name. The owner name may be used (along with the current "principal") for access checks by stores that support ACLs, locking, or both.                                                                                                                                   |
| STD_PARENT_GUID       | VARCHAR2 (32) | 'std:parent_guid'       | TYPECODE_NUMBER: A store-specific unique identifier for the parent of a path name. Clients must not depend on the GUID being unique across different stores, but a given ( <i>store-name</i> , <i>store-specific-path name</i> ) has a stable and unique GUID for its lifetime.<br><br>STD_PARENT_GUID(path name) ==<br>STD_GUID(parent(path name)) |
| STD_REFERENT          | VARCHAR2 (32) | 'std:referent'          | TYPECODE_VARCHAR2: The content of the symbolic link of a TYPE_LINK path; NULL otherwise. As mentioned, the STD_REFERENT can be an arbitrary string and must not necessarily be interpreted as path name by clients (or such interpretation should be done with great care).                                                                         |

### Optional Property Constants

Optional properties are well-defined properties (not mandatory) associated with all content path names that all stores are free to support (but only in the manner described by the DBFS content API).

All optional properties informally use the `opt:` namespace, which clients and stores should avoid using.

**Table 53-8 DBMS\_DBFS\_CONTENT Constants - Optional Properties**

| Constant         | Type          | Value              | Description                                                                                                                                                                                                                                                                   |
|------------------|---------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OPT_HASH_TYPE    | VARCHAR2 (32) | 'opt:hash_type'    | TYPECODE_NUMBER: The type of hash provided in the <code>opt_hash_value</code> property; see <a href="#">DBMS_CRYPTO</a> for possible options.                                                                                                                                 |
| OPT_HASH_VALUE   | VARCHAR2 (32) | 'opt:hash_value'   | TYPECODE_NUMBER: The hash value of type <code>OPT_HASH_TYPE</code> describing the content of the path name.                                                                                                                                                                   |
| OPT_LOCK_COUNT   | VARCHAR2 (32) | 'opt:lock_count'   | TYPECODE_NUMBER: The number of (compatible) locks placed on a path name. If different principals are allowed to place compatible (read) locks on a path, the <code>opt_locker</code> must specify all lockers (with repeats so that lock counts can be correctly maintained). |
| OPT_LOCK_DATA    | VARCHAR2 (32) | 'opt:lock_data'    | TYPECODE_NUMBER: The client-supplied user-data associated with a user-lock, uninterpreted by the store.                                                                                                                                                                       |
| OPT_LOCKER       | VARCHAR2 (32) | 'opt:locker'       | TYPECODE_NUMBER: One or more implicit or client-specified principals that applied a user-lock on a path name.                                                                                                                                                                 |
| OPT_LOCK_STATUS  | VARCHAR2 (32) | 'opt:lock_status'  | TYPECODE_NUMBER: One of the <code>LOCK_READ_ONLY</code> , <code>LOCK_WRITE_ONLY</code> , <code>LOCK_READ_WRITE</code> values describing the type of lock currently applied on a path name.                                                                                    |
| OPT_VERSION      | VARCHAR2 (32) | 'opt:version'      | TYPECODE_NUMBER: A sequence number for linear versioning of a path name.                                                                                                                                                                                                      |
| OPT_VERSION_PATH | VARCHAR2 (32) | 'opt:version_path' | TYPECODE_NUMBER: A version-path name for hierarchical versioning of a path name.                                                                                                                                                                                              |
| OPT_CONTENT_ID   | VARCHAR2 (32) | 'opt:content_id'   | TYPECODE_NUMBER: A provider-generated store-specific unique contentID in the form of a string for a file content element (that may optionally not be associated with a path; see <code>FEATURE_CONTENT_ID</code> and <code>FEATURE_LAZY_PATH</code> ).                        |

## Property Access Flag Constants

Content interface methods to get or set properties can use combinations of property access flags to fetch properties from different name spaces in a single interface call.

**Table 53-9 DBMS\_DBFS\_CONTENT Constants - Property Access Flags**

| Constant  | Type        | Value                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROP_NONE | PLS_INTEGER | 0                                               | None: used when the client is not interested in any properties, and is invoking the content access method for other reasons (path name existence or lockability validation, data access, and so on)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PROP_STD  | PLS_INTEGER | 1                                               | Mandatory: used when the client is interested in the standard properties; all standard properties are retrieved if this flag is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PROP_OPT  | PLS_INTEGER | 2                                               | Optional: used when the client is interested in the optional properties; all optional properties are retrieved if this flag is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PROP_USR  | PLS_INTEGER | 3                                               | User-defined: used when the client is interested in the user-defined properties; all user-defined properties are retrieved if this flag is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| PROP_ALL  | PLS_INTEGER | PROP_STD<br>+<br>PROP_OPT<br>+<br>PROP_USR<br>; | All: an alias for the combination of all standard, optional, and user-defined properties                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PROP_DATA | PLS_INTEGER | 8                                               | Content: used when the client is interested only in data access, and does not care about properties                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PROP_SPC  | PLS_INTEGER | 16                                              | Specific: used when the client is interested in a mix-and-match of different subsets of various property name spaces; the names of the specific properties to fetch are passed into the content interface method call as arguments, and only these property values are fetched and returned to the client. This is useful in cases where there are a very large number of properties potentially accessible, but the client is interested in only a small number of them (and knows the names of these "interesting" properties beforehand).<br><br>PROP_SPC is applicable only to the various GETPATH operations. Other operations that specify properties ignore PROP_SPC specifications. |

## Operation Code Constants

All of the operations in the DBFS content API are represented as abstract opcodes.

Clients can use these opcodes to directly and explicitly by invoking the [CHECKACCESS Function](#) to verify if a particular operation can be invoked by a given principal on a particular path name.

**Table 53-10 DBMS\_DBFS\_CONTENT Constants - Operation Codes**

| Constant           | Type        | Value     | Description                                                                   |
|--------------------|-------------|-----------|-------------------------------------------------------------------------------|
| OP_CREATE          | PLS_INTEGER | 1         | Create a path item                                                            |
| OP_CREATEFILE      | PLS_INTEGER | OP_CREATE | Create a file                                                                 |
| OP_CREATELINK      | PLS_INTEGER | OP_CREATE | Create a soft link                                                            |
| OP_CREATEREference | PLS_INTEGER | OP_CREATE | Create a reference (hard link)                                                |
| OP_DELETE          | PLS_INTEGER | 2         | Soft-deletion, purge, and restore operations are all represented by OP_DELETE |
| OP_DELETEFILE      | PLS_INTEGER | OP_DELETE | Delete a file                                                                 |
| OP_DELETEDIRECTORY | PLS_INTEGER | OP_DELETE | Delete a directory                                                            |
| OP_RESTORE         | PLS_INTEGER | OP_DELETE | Restore a soft-deleted path item                                              |
| OP_PURGE           | PLS_INTEGER | OP_DELETE | Purge a soft-deleted path item                                                |
| OP_READ            | PLS_INTEGER | 3         | Read from a path item                                                         |
| OP_GET             | PLS_INTEGER | OP_READ   | Get a path item for either read or update operations                          |
| OP_WRITE           | PLS_INTEGER | 4         | Write a path item                                                             |
| OP_PUT             | PLS_INTEGER | OP_WRITE  | Put (write) to a path item                                                    |
| OP_RENAME          | PLS_INTEGER | 5         | Rename a path item                                                            |
| OP_RENAMEFROM      | PLS_INTEGER | OP_RENAME | Operations performed on the source of a rename                                |
| OP_RENAMETO        | PLS_INTEGER | OP_RENAME | Operations performed on the destination of a rename                           |
| OP_SETPATH         | PLS_INTEGER | OP_RENAME | Set a path item name                                                          |
| OP_LIST            | PLS_INTEGER | 6         | Perform a path listing                                                        |
| OP_SEARCH          | PLS_INTEGER | 7         | Perform a search                                                              |
| OP_LOCK            | PLS_INTEGER | 8         | Lock a path item                                                              |
| OP_UNLOCK          | PLS_INTEGER | 9         | Unlock a path item                                                            |

**Table 53-10 (Cont.) DBMS\_DBFS\_CONTENT Constants - Operation Codes**

| Constant | Type        | Value | Description                                                                                                                                                                                    |
|----------|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP_ACL   | PLS_INTEGER | 10    | An implicit operation invoked during an OP_CREATE or OP_PUT that specifies a STD_ACL property; the operation tests to see if the principal is allowed to set or change the ACL of a store item |
| OP_STORE | PLS_INTEGER | 11    | A catch-all category for miscellaneous store operations that do not fall under any of the other operational interfaces                                                                         |

## 53.4 Exceptions

DBFS content API operations can raise any one of these top-level exceptions.

**Table 53-11 DBMS\_DBFS\_CONTENT Exceptions**

| Exception             | Code  | Description                                                    |
|-----------------------|-------|----------------------------------------------------------------|
| PATH_EXISTS           | 64000 | A specified path name already exists                           |
| INVALID_PARENT        | 64001 | Parent of a specified path name does not exist                 |
| INVALID_PATH          | 64002 | Specified path name does not exist, or is not valid            |
| UNSUPPORTED_OPERATION | 64003 | An operation unsupported by a store was invoked                |
| INVALID_ARGUMENTS     | 64004 | An operation was invoked with invalid arguments                |
| INVALID_ACCESS        | 64005 | Access control checks failed for the current operation         |
| LOCK_CONFLICT         | 64006 | Current operation failed lock conflict check                   |
| INVALID_STORE         | 64007 | An invalid store name was specified                            |
| INVALID_MOUNT         | 64008 | An invalid mount point was specified                           |
| INVALID_PROVIDER      | 64009 | An invalid provider-package was specified                      |
| READONLY_PATH         | 64010 | A mutating operation was invoked on a read-only mount or store |

## 53.5 DBMS\_DBFS\_CONTENT Operational Notes

This topic lists operational notes for DBMS\_DBFS\_CONTENT implementation, path names, and other operations.

- [Implementation](#)
- [Path Names](#)
- [Other DBMS\\_DBFS\\_CONTENT Operations](#)

### Implementation

Since the interconnection of the [DBMS\\_DBFS\\_CONTENT](#) interface and the provider SPI is a 1-to-many pluggable architecture, the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

There are no explicit `INIT` or `FINI` methods to indicate when the `DBMS_DBFS_CONTENT` interface plugs or unplugs a particular provider SPI. Provider SPIs must be willing to auto-initialize themselves at any SPI entry-point.

All operations performed by a store provider are "stateless" in that they are complete operations unto themselves. If state is necessary to be maintained for some reason, then the state must be maintained in data structures such as auxiliary tables that can be queried as needed.

### Path Names

All path names used in the provider SPI are store-qualified in pair form (`store_name`, `pathname`) where the path name is rooted within the store namespace.

Stores and their providers that support contentID-based access (see `FEATURE_CONTENT_ID` in [Table 53-5](#)) also support a form of addressing that is not based on path names. Content items are identified by an explicit store name, a `NULL` path name, and possibly a contentID specified as a parameter or by way of the `OPT_CONTENT_ID` (see [Table 53-8](#)) property.

Not all operations are supported with contentID-based access, and applications should depend only on the simplest create or delete functionality being available.

This table lists other operations and provides links to related discussions.

### Other DBMS\_DBFS\_CONTENT Operations

**Table 53-12 Other DBMS\_DBFS\_CONTENT Operations**

| Other Operations                | See ...                                                                                                                            |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Creation                        | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on creation operations              |
| Deletion                        | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on deletion operations              |
| Get (Retrieve) and Put (Insert) | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on Get and Put operations           |
| Rename and Move                 | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on Rename and Move operations       |
| Directory Navigation and Search | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on Navigation and Search operations |
| Locking                         | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on Locking operations               |
| Access Check                    | <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> for further information on Access Check operations          |

## 53.6 DBMS\_DBFS\_CONTENT Data Structures

The `DBMS_DBFS_CONTENT` package defines `RECORD` types and `TABLE` types.

### RECORD Types

- [FEATURE\\_T Record Type](#)
- [MOUNT\\_T Record Type](#)
- [PATH\\_ITEM\\_T Record Type](#)

- [PROP\\_ITEM\\_T Record Type](#)
- [PROPERTY\\_T Record Type](#)
- [STORE\\_T Record Type](#)

**TABLE Types**

- [FEATURES\\_T Table Type](#)
- [MOUNTS\\_T Table Type](#)
- [PATH\\_ITEMS\\_T Table Type](#)
- [PROP\\_ITEMS\\_T Table Type](#)
- [PROPERTIES\\_T Table Type](#)
- [STORES\\_T Table Type](#)

**Usage Notes**

There is an approximate correspondence between `DBMS_DBFS_CONTENT_PROPERTY_T` and `PROPERTY_T` — the former is a SQL object type that describes the full property tuple, while the latter is a PL/SQL record type that describes only the property value component.

Likewise, there is an approximate correspondence between `DBMS_DBFS_CONTENT_PROPERTIES_T` and `PROPERTIES_T` — the former is a SQL nested table type, while the latter is a PL/SQL hash table type.

Dynamic SQL calling conventions force the use of SQL types, but PL/SQL code may be implemented more conveniently in terms of the hash-table types.

The `DBMS_DBFS_CONTENT` interface provides convenient utility functions to convert between `DBMS_DBFS_CONTENT_PROPERTIES_T` and `PROPERTIES_T` (see `propertiesT2H` and `propertiesH2T`).

Clients can query the `DBMS_DBFS_CONTENT` interface for the list of available stores, determine which store is to handle access to a given path name, and determine the feature set for the store.

### 53.6.1 DBMS\_DBFS\_CONTENT FEATURE\_T Record Type

This type describes a store mount point and its properties.

**Syntax**

```
TYPE feature_t IS RECORD (  
    feature_name    VARCHAR2(32),  
    feature_mask    INTEGER,  
    feature_state   VARCHAR2(3));
```

**Fields**

**Table 53-13** MOUNT\_T Fields

| Field                     | Description                                                                        |
|---------------------------|------------------------------------------------------------------------------------|
| <code>feature_name</code> | Name of feature                                                                    |
| <code>feature_mask</code> | Value used to mask off all other bits other than this feature in the feature value |

**Table 53-13 (Cont.) MOUNT\_T Fields**

| Field         | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| feature_state | 'YES' or 'NO' depending on whether the feature is supported on this store |

## 53.6.2 DBMS\_DBFS\_CONTENT MOUNT\_T Record Type

This type describes a store mount point and its properties.

### Syntax

```
TYPE mount_t IS RECORD (  
    store_name          VARCHAR2(32),  
    store_id            NUMBER,  
    provider_name       VARCHAR2(32),  
    provider_pkg        VARCHAR2(32),  
    provider_id         NUMBER,  
    provider_version    VARCHAR2(32),  
    store_features      INTEGER,  
    store_guid          NUMBER,  
    store_mount         NAME_T,  
    mount_properties    DBMS_DBFS_CONTENT_PROPERTIES_T);
```

### Fields

**Table 53-14 MOUNT\_T Fields**

| Field            | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| store_name       | Name of store                                                                                    |
| store_id         | ID of store                                                                                      |
| provider_name    | Name of the content store                                                                        |
| provider_pkg     | PL/SQL package name for the content store                                                        |
| provider_id      | Unique identifier for the content store                                                          |
| provider_version | Version number for the content store                                                             |
| respos_features  | Features supported by this content store                                                         |
| store_guid       | Unique ID for this instance of the store                                                         |
| store_mount      | Location at which this store instance is mounted                                                 |
| mount_properties | Properties for this mount point (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |

## 53.6.3 DBMS\_DBFS\_CONTENT PATH\_ITEM\_T Record Type

A `PATH_ITEM_T` is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

### Syntax

```
TYPE path_item_t IS RECORD (  
    store              NAME_T,
```

|                       |                 |
|-----------------------|-----------------|
| mount                 | NAME_T,         |
| pathname              | PATH_T,         |
| pathtype              | VARCHAR2(32),   |
| filedata              | BLOB,           |
| std_access_time       | TIMESTAMP,      |
| std_acl               | VARCHAR2(1024), |
| std_change_time       | TIMESTAMP,      |
| std_children          | NUMBER,         |
| std_content_type      | VARCHAR2(1024), |
| std_creation_time     | TIMESTAMP,      |
| std_deleted           | INTEGER,        |
| std_guid              | INTEGER,        |
| std_modification_time | TIMESTAMP,      |
| std_owner             | VARCHAR2(32),   |
| std_parent_guid       | INTEGER,        |
| std_referent          | VARCHAR2(1024), |
| opt_hash_type         | VARCHAR2(32),   |
| opt_hash_value        | VARCHAR2(128),  |
| opt_lock_count        | INTEGER,        |
| opt_lock_data         | VARCHAR2(128),  |
| opt_locker            | VARCHAR2(128),  |
| opt_lock_status       | INTEGER,        |
| opt_version           | INTEGER,        |
| opt_version_path      | PATH_T,         |
| opt_content_id        | CONTENT_ID_T);  |

## Fields

**Table 53-15** PATH\_ITEM\_T Fields

| Field             | Description                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store             | Name of store                                                                                                                                                                                                                             |
| mount             | Location at which instance of store is mounted                                                                                                                                                                                            |
| pathname          | Name of path to item                                                                                                                                                                                                                      |
| pathtype          | Type of object path (see <a href="#">Table 53-4</a> )                                                                                                                                                                                     |
| filedata          | BLOB locator that can be used to access data in the path item                                                                                                                                                                             |
| std_access_time   | Time of last access of a pathname's contents                                                                                                                                                                                              |
| std_acl           | Access Control List (in standard ACL syntax)                                                                                                                                                                                              |
| std_change_time   | Time of last change to the metadata of a path name                                                                                                                                                                                        |
| std_children      | Number of child directories or folders a directory or folder path (this property should be available in providers that support the <code>feature_folders</code> feature).                                                                 |
| std_content_type  | One or more client-supplied mime-types (in standard RFC syntax) describing the path name which is typically of <code>type_file</code> . The content type s not necessarily interpreted by the store.                                      |
| std_creation_time | Time at which the item was created. Once set, this value remains the same for the lifetime of the path name.                                                                                                                              |
| std_deleted       | Set to a nonzero number if the path name has been soft-deleted but not yet purged (see <a href="#">Table 53-5</a> )                                                                                                                       |
| std_guid          | Store-specific unique identifier for a path name. Clients must not depend on the GUID being unique across different stores, but a given <i>store-name</i> , <i>store-specific-pathname</i> has a stable and unique GUID for its lifetime. |

**Table 53-15 (Cont.) PATH\_ITEM\_T Fields**

| Field                 | Description                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| std_modification_time | Time of last change to the data associated with a path name. Changes to the content of a <code>type_file</code> or <code>type_reference</code> path, the referent of the <code>type_link</code> path, and addition or deletion of immediate children in a <code>type_directory</code> path, all constitute data changes.            |
| std_owner             | Client-supplied (or implicit) owner name for the path name                                                                                                                                                                                                                                                                          |
| std_parent_guid       | Store-specific unique identifier for the parent of a path name. Clients must not depend on the GUID being unique across different stores, but a given <i>store-name</i> , <i>store-specific-pathname</i> has a stable and unique GUID for its lifetime.<br><br><code>std_parent_guid(pathname) == std_guid(parent(pathname))</code> |
| std_referent          | Content of the symbolic link of a <code>type_link</code> path, otherwise NULL. As mentioned before, the <code>std_referent</code> can be an arbitrary string and must not necessarily be interpreted as pathname by clients (or such interpretation should be done with great care).                                                |
| opt_hash_type         | Type of hash provided in the <code>opt_hash_value</code> property (see <a href="#">DBMS_CCRYPTO</a> for possible options)                                                                                                                                                                                                           |
| opt_hash_value        | Hash value of type <code>opt_hash_type</code> describing the content of the path name                                                                                                                                                                                                                                               |
| opt_lock_count        | Number of compatible locks placed on a path name. If different principals are allowed to place compatible (read) locks on a path, the <code>opt_locker</code> must specify all lockers with repeats so that lock counts can be correctly maintained.                                                                                |
| opt_lock_data         | Client-supplied user-data associated with a user-lock, uninterpreted by the store                                                                                                                                                                                                                                                   |
| opt_locker            | One or more implicit or client-specified principals that applied a user-lock on a path name                                                                                                                                                                                                                                         |
| opt_lock_status       | One of the <code>lock_read_only</code> , <code>lock_write_only</code> , <code>lock_read_write</code> values describing the type of lock currently applied on a path name                                                                                                                                                            |
| opt_version           | Sequence number for linear versioning of a path name                                                                                                                                                                                                                                                                                |
| opt_version_path      | Version path name for hierarchical versioning of a path name                                                                                                                                                                                                                                                                        |
| opt_content_id        | Stringified provider-generated store-specific unique contentID for a file element (that may optionally not be associated with a path (see <code>FEATURE_CONTENT_ID</code> and <code>FEATURE_LAZY_PATH</code> in <a href="#">Table 53-5</a> ))                                                                                       |

## 53.6.4 DBMS\_DBFS\_CONTENT PROP\_ITEM\_T Record Type

A `PROP_ITEM_T` is a tuple describing a (*store*, *mount*) qualified path in a store, with all user-defined properties associated with it, expanded out into individual (*name*, *value*, *type*) tuples.

### Syntax

```

TYPE prop_item_t IS RECORD (
    store           NAME_T,
    mount           NAME_T,
    pathname        PATH_T,
    property_name    PROPNAME_T,

```

```
property_value    PROPVAL_T,  
property_type     INTEGER);
```

## Fields

**Table 53-16** PROP\_ITEM\_T Fields

| Field          | Description                                    |
|----------------|------------------------------------------------|
| store          | Name of store                                  |
| mount          | Location at which instance of store is mounted |
| pathname       | Name of path to item                           |
| property_name  | Name of the property                           |
| property_value | Value of the property                          |
| property_type  | PL/SQL typecode for the property value         |

## 53.6.5 PROPERTY\_T Record Type

This type describes a single (value, typecode) property value tuple; the property name is implied.

See [PROPERTIES\\_T Table Type](#) for more information.

### Syntax

```
TYPE property_t IS RECORD (  
    propvalue    PROPVAL_T,  
    typecode     INTEGER);
```

## Fields

**Table 53-17** PROPERTY\_T Fields

| Field     | Description       |
|-----------|-------------------|
| propvalue | Value of property |
| typecode  | Typecode          |

## 53.6.6 DBMS\_DBFS\_CONTENT STORE\_T Record Type

This type describes a store registered with and managed by the DBMS\_DBFS\_CONTENT interface.

### Syntax

```
TYPE store_t IS RECORD (  
    store_name    VARCHAR2(32),  
    store_id      NUMBER,  
    provider_name VARCHAR2(32),  
    provider_pkg  VARCHAR2(32),  
    provider_id   NUMBER,  
    provider_version VARCHAR2(32),  
    store_features INTEGER,  
    store_guid    NUMBER);
```

## Fields

**Table 53-18 STORET\_T Fields**

| Field            | Description                               |
|------------------|-------------------------------------------|
| store_name       | Name of store                             |
| store_id         | ID of store                               |
| provider_name    | Name of the content store                 |
| provider_pkg     | PL/SQL package name for the content store |
| provider_id      | Unique identifier for the content store   |
| provider_version | Version number for the content store      |
| respos_features  | Features supported by this content store  |
| store_guid       | Unique ID for this instance of the store  |

### 53.6.7 DBMS\_DBFS\_CONTENT FEATURES\_T Table Type

A table type of FEATURE\_T Record Type.

#### Syntax

```
TYPE features_t IS TABLE OF feature_t;
```

#### Related Topics

- [DBMS\\_DBFS\\_CONTENT FEATURE\\_T Record Type](#)  
This type describes a store mount point and its properties.

### 53.6.8 MOUNTS\_T Table Type

A table type of MOUNT\_T Record Type.

#### Syntax

```
TYPE mounts_t IS TABLE OF mount_t;
```

#### Related Topics

- [DBMS\\_DBFS\\_CONTENT MOUNT\\_T Record Type](#)  
This type describes a store mount point and its properties.

### 53.6.9 DBMS\_DBFS\_CONTENT PATH\_ITEMS\_T Table Type

A table type of PATH\_ITEM\_T Record Type

#### Syntax

```
TYPE path_items_t IS TABLE OF path_item_t;
```

#### Related Topics

- [DBMS\\_DBFS\\_CONTENT PATH\\_ITEM\\_T Record Type](#)  
A PATH\_ITEM\_T is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

## 53.6.10 DBMS\_DBFS\_CONTENT PROP\_ITEMS\_T Table Type

A table type of PATH\_ITEM\_T Record Type.

### Syntax

```
TYPE prop_items_t IS TABLE OF prop_item_t;
```

### Related Topics

- [DBMS\\_DBFS\\_CONTENT PATH\\_ITEM\\_T Record Type](#)  
A PATH\_ITEM\_T is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

## 53.6.11 DBMS\_DBFS\_CONTENT PROPERTIES\_T Table Type

This is a name-indexed hash table of property tuples. The implicit hash-table association between the index and the value allows the client to build up the full DBMS\_DBFS\_CONTENT\_PROPERTY\_T tuples for a PROPERTIES\_T.

### Syntax

```
TYPE properties_t IS TABLE OF property_t INDEX BY propname_t;
```

## 53.6.12 STORES\_T Table Type

This type describes a store registered with and managed by the DBMS\_DBFS\_CONTENT interface.

### Syntax

```
TYPE stores_t IS TABLE OF store_t;
```

## 53.7 Summary of DBMS\_DBFS\_CONTENT Subprograms

This table lists and describes the subprograms used in the DBMS\_DBFS\_CONTENT Package.

**Table 53-19 DBMS\_DBFS\_CONTENT Package Subprograms**

| Subprogram                                        | Description                                                                                                                                           |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">CHECKACCESS Function</a>              | Reports if the user (principal) can perform the specified operation on the given path                                                                 |
| <a href="#">CHECKSPI Functions and Procedures</a> | Checks if a user-provided package implements all of the DBMS_DBFS_CONTENT_SPI subprograms with the proper signatures, and reports on the conformance. |
| <a href="#">CREATEDIRECTORY Procedures</a>        | Creates a directory                                                                                                                                   |
| <a href="#">CREATEFILE Procedures</a>             | Creates a file                                                                                                                                        |
| <a href="#">CREATELINK Procedures</a>             | Creates a new reference to the source file system element                                                                                             |
| <a href="#">CREATEREFERENCE Procedures</a>        | Creates a physical link to an already existing file system element                                                                                    |
| <a href="#">DECODEFEATURES Function</a>           | Given a feature bit set integer value, returns a FEATURES_T table of the feature bits as FEATURE_T records                                            |
| <a href="#">DELETECONTENT Procedure</a>           | Deletes the file specified by the given contentID                                                                                                     |

**Table 53-19 (Cont.) DBMS\_DBFS\_CONTENT Package Subprograms**

| Subprogram                                    | Description                                                                                                                                                          |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DELETEDIRECTORY Procedure</a>     | Deletes a directory                                                                                                                                                  |
| <a href="#">DELETEFILE Procedure</a>          | Deletes a file                                                                                                                                                       |
| <a href="#">FEATURENAME Function</a>          | Given a feature bit, returns a <code>VARCHAR2</code> of that feature's name                                                                                          |
| <a href="#">FLUSHSTATS Function</a>           | Flushes <code>DBMS_DBFS_CONTENT</code> statistics to disk                                                                                                            |
| <a href="#">GETDEFAULTACL Procedure</a>       | Returns the <code>ACL</code> parameter of the default context                                                                                                        |
| <a href="#">GETDEFAULTASOF Procedure</a>      | Returns the <code>asof</code> parameter of the default context                                                                                                       |
| <a href="#">GETTDEFAULTCONTEXT Procedure</a>  | Returns the default context                                                                                                                                          |
| <a href="#">GETDEFAULTTOWNER Procedure</a>    | Returns the <code>owner</code> parameter of the default context                                                                                                      |
| <a href="#">GETDEFAULTPRINCIPAL Procedure</a> | Returns the <code>principal</code> parameter of the default context                                                                                                  |
| <a href="#">GETFEATURESBYMOUNT Function</a>   | Returns features of a store by mount point                                                                                                                           |
| <a href="#">GETFEATURESBYNAME Function</a>    | Returns features of a store by store name                                                                                                                            |
| <a href="#">GETFEATURESBYPATH Function</a>    | Returns features of a store by path                                                                                                                                  |
| <a href="#">GETPATHBYMOUNTID Function</a>     | Returns the full absolute path name                                                                                                                                  |
| <a href="#">GETPATH Procedures</a>            | Returns existing path items (such as files and directories)                                                                                                          |
| <a href="#">GETPATHBYSTOREID Function</a>     | If the underlying GUID is found in the underlying store, returns the store-qualified path name                                                                       |
| <a href="#">GETPATHNOWAIT Procedures</a>      | Implies that the operation is for an update, and, if implemented, allows providers to return an exception ( <code>ORA-00054</code> ) rather than wait for row locks. |
| <a href="#">GETSTOREBYMOUNT Function</a>      | Returns a store by way of its mount point                                                                                                                            |
| <a href="#">GETSTOREBYNAME Function</a>       | Returns a store by way of its name                                                                                                                                   |
| <a href="#">GETSTOREBYPATH Function</a>       | Returns a store by way of its path                                                                                                                                   |
| <a href="#">GETSTATS Procedure</a>            | Returns information about <code>DBMS_DBFS_CONTENT</code> statistics collection                                                                                       |
| <a href="#">GETTRACE Function</a>             | Returns whether or not <code>DBMS_DBFS_CONTENT</code> tracing is turned on                                                                                           |
| <a href="#">GETVERSION Function</a>           | Returns the version of the <code>DBMS_DBFS_CONTENT</code> interface in a standardized format associated with a store                                                 |
| <a href="#">LIST Function</a>                 | Lists the path items in the specified path meeting the specified filter and other criteria                                                                           |
| <a href="#">LISTALLCONTENT Function</a>       | Lists all path items in all mounts                                                                                                                                   |
| <a href="#">LISTALLPROPERTIES Function</a>    | Returns a table of all properties for all path items in all mounts                                                                                                   |
| <a href="#">LISTMOUNTS Function</a>           | Lists all available mount points, their backing stores, and the store features                                                                                       |
| <a href="#">LISTSTORES Function</a>           | Lists all available stores and their features                                                                                                                        |
| <a href="#">LOCKPATH Procedure</a>            | Applies user-level locks to the given valid path name                                                                                                                |
| <a href="#">MOUNTSTORE Procedure</a>          | Mounts a previously registered store and binds it to the mount point                                                                                                 |
| <a href="#">NORMALIZEPATH Functions</a>       | Converts a store-specific or full-absolute path name into normalized form                                                                                            |

**Table 53-19 (Cont.) DBMS\_DBFS\_CONTENT Package Subprograms**

| Subprogram                                    | Description                                                                                                                           |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">PROPANY Functions</a>             | Provides constructors that take one of a variety of types and return a <code>PROPERTY_T</code>                                        |
| <a href="#">PROPERTIESH2T Function</a>        | Converts a <code>PROPERTY_T</code> hash to a <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> table                                        |
| <a href="#">PROPERTIEST2H Function</a>        | Converts a <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> table to a <code>PROPERTY_T</code> hash                                        |
| <a href="#">PROPNUMBER Function</a>           | Is a constructor that takes a <code>NUMBER</code> and returns a <code>PROPERTY_T</code>                                               |
| <a href="#">PROPRAW Function</a>              | Is a constructor that takes a <code>RAW</code> and returns a <code>PROPERTY_T</code>                                                  |
| <a href="#">PROPTIMESTAMP Function</a>        | Is a constructor that takes a <code>TIMESTAMP</code> and returns a <code>PROPERTY_T</code>                                            |
| <a href="#">PROPVARCHAR2 Function</a>         | Is a constructor that takes a <code>VARCAHR2</code> and returns a <code>PROPERTY_T</code>                                             |
| <a href="#">PURGEALL Procedure</a>            | Purges all soft-deleted entries matching the path and optional filter criteria                                                        |
| <a href="#">PURGEPATH Procedure</a>           | Purges any soft-deleted versions of the given path item                                                                               |
| <a href="#">PUTPATH Procedures</a>            | Creates a new path item                                                                                                               |
| <a href="#">REGISTERSTORE Procedure</a>       | Registers a new store                                                                                                                 |
| <a href="#">RENAMEPATH Procedures</a>         | Renames or moves a path                                                                                                               |
| <a href="#">RESTOREALL Procedure</a>          | Restores all soft-deleted path items meeting the path and filter criteria                                                             |
| <a href="#">RESTOREPATH Procedure</a>         | Restores all soft-deleted path items that match the given path and filter criteria                                                    |
| <a href="#">SETDEFAULTACL Procedure</a>       | Sets the ACL parameter of the default context                                                                                         |
| <a href="#">SETDEFAULTASOF Procedure</a>      | Sets the "as of" parameter of the default context                                                                                     |
| <a href="#">SETDEFAULTCONTEXT Procedure</a>   | Sets the default context                                                                                                              |
| <a href="#">SETDEFAULTOWNER Procedure</a>     | Sets the "owner" parameter of the default context                                                                                     |
| <a href="#">SETDEFAULTPRINCIPAL Procedure</a> | Sets the "principal" parameter of the default context                                                                                 |
| <a href="#">SETPATH Procedures</a>            | Assigns a path name to a path item represented by contentID                                                                           |
| <a href="#">SETSTATS Procedure</a>            | Enables and disables statistics collection                                                                                            |
| <a href="#">SETTRACE Procedure</a>            | Sets <code>DBMS_DBFS_CONTENT</code> tracing on or off                                                                                 |
| <a href="#">SPACEUSAGE Procedure</a>          | Queries file system space usage statistics                                                                                            |
| <a href="#">TRACE Procedure</a>               | Returns a <code>CLOB</code> that contains the evaluation results                                                                      |
| <a href="#">TRACEENABLED Function</a>         | Determines if the current trace "severity" set by the <a href="#">SETTRACE Procedure</a> is at least as high as the given trace level |
| <a href="#">UNLOCKPATH Procedure</a>          | Unlocks path items that were previously locked with the <a href="#">LOCKPATH Procedure</a>                                            |
| <a href="#">UNMOUNTSTORE Procedure</a>        | Unmounts a registered store                                                                                                           |
| <a href="#">UNREGISTERSTORE Procedure</a>     | Unregisters a store                                                                                                                   |

## 53.7.1 CHECKACCESS Function

This function reports if the user (*principal*) can perform the specified operation on the given path. This enables verifying the validity of an operation without attempting to perform the operation. If `CHECKACCESS` returns 0, then the subprogram invoked to implement that operation should fail with an error.

### Syntax

```
DBMS_DBFS_CONTENT.CHECKACCESS (
    path          IN      VARCHAR2,
    pathtype      IN      INTEGER,
    operation     IN      VARCHAR2,
    principal     IN      VARCHAR2,
    store_name    IN      VARCHAR2 DEFAULT NULL)
RETURN BOOLEAN;
```

### Parameters

**Table 53-20 CHECKACCESS Procedure Parameters**

| Parameter  | Description                                                             |
|------------|-------------------------------------------------------------------------|
| path       | Name of path to check for access                                        |
| pathtype   | Type of object <i>path</i> represents (see <a href="#">Table 53-4</a> ) |
| operation  | Operation to be checked (see <a href="#">Table 53-8</a> )               |
| principal  | File system user for whom the access check is made                      |
| store_name | Name of store                                                           |

### Usage Notes

Whether or not the user invokes this function, a store that supports access control internally performs these checks to guarantee security.

## 53.7.2 CHECKSPI Functions and Procedures

Given the name of a putative `DBMS_DBFS_CONTENT_SPI` conforming package, this function or procedure checks whether the package implements all of the provider subprograms with the proper signatures, and reports on the conformance.

### Syntax

```
DBMS_DBFS_CONTENT.CHECKSPI (
    package_name IN      VARCHAR2)
RETURN CLOB;
```

```
DBMS_DBFS_CONTENT.CHECKSPI (
    schema_name IN      VARCHAR2,
    package_name IN      VARCHAR2)
return clob;
```

```
DBMS_DBFS_CONTENT.CHECKSPI (
    package_name IN      VARCHAR2,
    chk          IN OUT NOCOPY CLOB);
```

```
DBMS_DBFS_CONTENT.CHECKSPI (
    schema_name      in          VARCHAR2,
    package_name     in          VARCHAR2,
    chk              in out nocopy CLOB);
```

## Parameters

**Table 53-21 CHECKSPI Procedure Parameters**

| Parameter    | Description                               |
|--------------|-------------------------------------------|
| package_name | Name of package                           |
| schema_name  | Name of schema                            |
| chk          | CLOB that contains the evaluation results |

## Usage Notes

- The functional form returns a cached temporary LOB of session duration with the results of the analysis. The caller is expected to manage the lifetime of this LOB, as needed.
- The procedural form generates the results of the analysis into the `chk` LOB parameter; if the value passed in is `NULL`, the results are written to the foreground trace file provided that `DBMS_DBFS_CONTENT` interface tracing is enabled. If neither tracing is enabled nor a valid LOB passed in, the checker does not provide any useful indication of the analysis (other than raise exceptions if it encounters a serious error).
- If `schema_name` is `NULL`, standard name resolution rules (current schema, private synonym, public synonym) are used to try and locate a suitable package to analyze.

## 53.7.3 CREATEDIRECTORY Procedures

This procedure creates a directory.

## Syntax

```
DBMS_DBFS_CONTENT.CREATEDIRECTORY (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    prop_flags    IN          INTEGER    DEFAULT PROP_STD,
    recurse       IN          BOOLEAN   DEFAULT FALSE,
    store_name    IN          VARCHAR2  DEFAULT NULL,
    principal     IN          VARCHAR2  DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.CREATEDIRECTORY (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    prop_flags    IN          INTEGER    DEFAULT PROP_STD,
    recurse       IN          BOOLEAN   DEFAULT FALSE,
    store_name    IN          VARCHAR2  DEFAULT NULL,
    principal     IN          VARCHAR2  DEFAULT NULL);
```

## Parameters

**Table 53-22 CREATEDIRECTORY Procedure Parameters**

| Parameter | Description                   |
|-----------|-------------------------------|
| path      | Name of path to the directory |

**Table 53-22 (Cont.) CREATEDIRECTORY Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| properties | One or more properties and their values to be set, returned, or both, depending on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                                                               |
| prop_flags | Determines which properties are set, returned, or both. Default is <code>PROP_STD</code> . Specify properties to be returned by setting <code>PROP_SPC</code> (see <a href="#">Table 53-9</a> ), and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| recurse    | If 0, do not execute recursively; otherwise, recursively create the directories above the given directory                                                                                                                                                                                                                                 |
| store_name | Name of store                                                                                                                                                                                                                                                                                                                             |
| principal  | File system user for whom the access check is made                                                                                                                                                                                                                                                                                        |

## 53.7.4 CREATEFILE Procedures

This procedure creates a file.

### Syntax

```
DBMS_DBFS_CONTENT.CREATEFILE (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content       IN OUT NOCOPY BLOB,
    prop_flags    IN          INTEGER          DEFAULT (PROP_STD + PROP_DATA),
    store_name    IN          VARCHAR2        DEFAULT NULL,
    principal     IN          VARCHAR2        DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATEFILE (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    content       IN OUT NOCOPY BLOB,
    prop_flags    IN          INTEGER          DEFAULT (PROP_STD + PROP_DATA),
    store_name    IN          VARCHAR2        DEFAULT NULL,
    principal     IN          VARCHAR2        DEFAULT NULL);
```

### Parameters

**Table 53-23 CREATEFILE Procedure Parameters**

| Parameter  | Description                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to the file                                                                                                                                                    |
| properties | One or more properties and their values to be set, returned, or both, depending on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> ) |
| content    | BLOB holding data with which to populate the file (optional)                                                                                                                |

**Table 53-23 (Cont.) CREATEFILE Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| store_name | Name of store                                                                                                                                                                                                                                                                 |
| principal  | File system user for whom the access check is made                                                                                                                                                                                                                            |

## 53.7.5 CREATELINK Procedures

This procedure creates a new link element `srcPath` with the value of `dstPath`. The value of `dstPath` is not validated or interpreted in any way by this procedure. This is analogous to a UNIX file system symbolic link.

### Syntax

```
DBMS_DBFS_CONTENT.CREATELINK (
    srcPath      IN          VARCHAR2,
    dstPath      IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    prop_flags    IN          INTEGER    DEFAULT PROP_STD,
    store_name    IN          VARCHAR2   DEFAULT NULL,
    principal     IN          VARCHAR2   DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATELINK (
    srcPath      IN          VARCHAR2,
    dstPath      IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    prop_flags    IN          INTEGER    DEFAULT PROP_STD,
    store_name    IN          VARCHAR2   DEFAULT NULL,
    principal     IN          VARCHAR2   DEFAULT NULL);
```

### Parameters

**Table 53-24 CREATELINK Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srcPath    | File system entry to create.                                                                                                                                                                                                                                                                |
| dstPath    | Value to associate with <code>srcPath</code> .                                                                                                                                                                                                                                              |
| properties | One or more properties and their values to be set, returned depending, or both, on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                 |
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting <code>prop_spec</code> , and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| store_name | Name of store                                                                                                                                                                                                                                                                               |
| principal  | File system user for whom the access check is made                                                                                                                                                                                                                                          |

## 53.7.6 CREATEREFERENCE Procedures

This procedure creates a physical link, `srcPath`, to an already existing file system element, `dstPath` (such as file or directory). The resulting entry shares the same metadata structures as the value of the `dstPath` parameter, and so is similar to incrementing a reference count on the file system element. This is analogous to a UNIX file system hard link.

### Syntax

```
DBMS_DBFS_CONTENT.CREATEREFERENCE (
  srcPath      IN          VARCHAR2,
  dstPath      IN          VARCHAR2,
  properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
  prop_flags    IN          INTEGER      DEFAULT PROP_STD,
  store_name    IN          VARCHAR2    DEFAULT NULL,
  principal     IN          VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATEREFERENCE (
  srcPath      IN          VARCHAR2,
  dstPath      IN          VARCHAR2,
  properties    IN OUT NOCOPY PROPERTIES_T,
  prop_flags    IN          INTEGER      DEFAULT PROP_STD,
  store_name    IN          VARCHAR2    DEFAULT NULL,
  principal     IN          VARCHAR2    DEFAULT NULL);
```

### Parameters

**Table 53-25 CREATEREFERENCE Procedure Parameters**

| Parameter               | Description                                                                                                                                                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>srcPath</code>    | File system entry to create.                                                                                                                                                                                                                                                                     |
| <code>dstPath</code>    | Path that is the reference to <code>srcPath</code> .                                                                                                                                                                                                                                             |
| <code>properties</code> | One or more properties and their values to be set, returned, or both, depending on <code>prop_flags</code> (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                      |
| <code>prop_flags</code> | Determines which properties are set, returned. Default is <code>PROP_STD</code> . Specify properties to be returned by setting <code>prop_spec</code> , and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| <code>store_name</code> | Name of store                                                                                                                                                                                                                                                                                    |
| <code>principal</code>  | File system user for whom the access check is made                                                                                                                                                                                                                                               |

## 53.7.7 DECODEFEATURES Function

Given a feature bit set integer value, this function returns a `FEATURES_T` table of the feature bits as `FEATURE_T` records.

### Syntax

```
DBMS_DBFS_CONTENT.DECODEFEATURES (
  featureSet      IN          INTEGER)
RETURN FEATURES_T DETERMINISTIC PIPELINED;
```

## Parameters

**Table 53-26 DECODEFEATURES Function Parameters**

| Parameter  | Description |
|------------|-------------|
| featureSet | Feature set |

## Return Values

[FEATURES\\_T Table Type](#)

## 53.7.8 DELETECONTENT Procedure

This procedure deletes the file specified by the given contentID.

### Syntax

```
DBMS_DBFS_CONTENT.DELETECONTENT (
    store_name      IN      VARCHAR2      DEFAULT NULL,
    contentID       IN      RAW,
    filter          IN      VARCHAR2      DEFAULT NULL,
    soft_delete     IN      BOOLEAN       DEFAULT NULL,
    principal       IN      VARCHAR2      DEFAULT NULL);
```

## Parameters

**Table 53-27 DELETECONTENT Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| store_name  | Name of store                                                                                                                                                                                  |
| contentID   | Unique identifier for the file to be deleted                                                                                                                                                   |
| filter      | A filter, if any, to be applied                                                                                                                                                                |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations). |
| principal   | File system user for whom the access check is made                                                                                                                                             |

## 53.7.9 DELETEDIRECTORY Procedure

This procedure deletes a directory.

If `recurse` is nonzero, it recursively deletes all elements of the directory. A filter, if supplied, determines which elements of the directory are deleted.

### Syntax

```
DBMS_DBFS_CONTENT.DELETEDIRECTORY (
    path           IN      VARCHAR2,
    filter         IN      VARCHAR2      DEFAULT NULL,
    soft_delete    IN      BOOLEAN       DEFAULT NULL,
    recurse       IN      BOOLEAN       DEFAULT FALSE,
    store_name     IN      VARCHAR2      DEFAULT NULL,
    principal      IN      VARCHAR2      DEFAULT NULL);
```

## Parameters

**Table 53-28 DELETEDIRECTORY Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path        | Name of path to the directory                                                                                                                                                                |
| filter      | A filter, if any, to be applied                                                                                                                                                              |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations. |
| recurse     | If 0, do not execute recursively. Otherwise, recursively delete the directories and files below the given directory.                                                                         |
| store_name  | Name of store                                                                                                                                                                                |
| principal   | File system user for whom the access check is made                                                                                                                                           |

## 53.7.10 DELETEFILE Procedure

This procedure deletes the specified file.

### Syntax

```
DBMS_DBFS_CONTENT.DELETEFILE (
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2  DEFAULT NULL,
    soft_delete   IN      BOOLEAN   DEFAULT NULL,
    store_name    IN      VARCHAR2  DEFAULT NULL,
    principal     IN      VARCHAR2  DEFAULT NULL);
```

## Parameters

**Table 53-29 DELETEFILE Procedure Parameters**

| Parameter   | Description                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path        | Name of path to the file                                                                                                                                                                       |
| filter      | A filter, if any, to be applied                                                                                                                                                                |
| soft_delete | If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i> , Deletion Operations). |
| store_name  | Name of store                                                                                                                                                                                  |
| principal   | File system user for whom the access check is made                                                                                                                                             |

## 53.7.11 FEATURENAME Function

Given a feature bit, this function returns a VARCHAR2 of that feature's name.

### Syntax

```
DBMS_DBFS_CONTENT.FEATURENAME (
    featureBit    IN      INTEGER)
RETURN VARCHAR2 DETERMINISTIC;
```

## Parameters

**Table 53-30 FEATURENAME Function Parameters**

| Parameter  | Description                                                         |
|------------|---------------------------------------------------------------------|
| featureBit | Bit representation of the feature (see <a href="#">Table 53-5</a> ) |

## Return Values

Name of the feature

## 53.7.12 FLUSHSTATS Function

This procedure flushes DBMS\_DBFS\_CONTENT statistics to disk.

### Syntax

```
DBMS_DBFS_CONTENT.FLUSHSTATS;
```

## 53.7.13 GETDEFAULTACL Procedure

This procedure returns the ACL parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTACL (  
    acl    OUT NOCOPY    VARCHAR2);
```

## Parameters

**Table 53-31 GETDEFAULTACL Procedure Parameters**

| Parameter | Description                                                                          |
|-----------|--------------------------------------------------------------------------------------|
| acl       | ACL for all new elements created (implicitly or explicitly) by the current operation |

## 53.7.14 GETDEFAULTASOF Procedure

This procedure returns the "as of" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTASOF (  
    asof    OUT NOCOPY    TIMESTAMP);
```

## Parameters

**Table 53-32 GETDEFAULTASOF Procedure Parameters**

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| asof      | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes |

## 53.7.15 GETDEFAULTCONTEXT Procedure

This procedure returns the default context. The information contained in the context can be inserted explicitly by way of arguments to the various method calls, allowing for fine-grained control over individual operations.

### Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTCONTEXT (
    principal    OUT NOCOPY    VARCHAR2,
    owner        OUT NOCOPY    VARCHAR2,
    acl          OUT NOCOPY    VARCHAR2,
    asof         OUT NOCOPY    TIMESTAMP);
```

## Parameters

**Table 53-33 GETDEFAULTCONTEXT Procedure Parameters**

| Parameter | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| principal | Agent (principal) invoking the current operation                                                             |
| owner     | Owner for new elements created (implicitly or explicitly) by the current operation                           |
| acl       | ACL for all new elements created (implicitly or explicitly) by the current operation                         |
| asof      | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes |

## 53.7.16 GETDEFAULTOWNER Procedure

This procedure returns the "owner" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTOWNER (
    principal    IN      VARCHAR2);
```

## Parameters

**Table 53-34 GETDEFAULTOWNER Procedure Parameters**

| Parameter | Description                                                                        |
|-----------|------------------------------------------------------------------------------------|
| owner     | Owner for new elements created (implicitly or explicitly) by the current operation |

## 53.7.17 GETDEFAULTPRINCIPAL Procedure

This procedure returns the "principal" parameter of the default context. This information contained can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

### Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTPRINCIPAL (  
    principal    OUT NOCOPY    VARCHAR2);
```

## Parameters

**Table 53-35 GETDEFAULTPRINCIPAL Procedure Parameters**

| Parameter | Description                                      |
|-----------|--------------------------------------------------|
| principal | Agent (principal) invoking the current operation |

## 53.7.18 GETFEATURESBYMOUNT Function

This function returns features of a store by mount point.

### Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYMOUNT (  
    store_mount    IN    VARCHAR2)  
RETURN INTEGER;
```

## Parameters

**Table 53-36 GETFEATURESBYMOUNT Function Parameters**

| Parameter   | Description |
|-------------|-------------|
| store_mount | Mount point |

### Return Values

A bit mask of supported features (see [FEATURES\\_T Table Type](#))

## 53.7.19 GETFEATURESBYNAME Function

This function returns features of a store by store name.

### Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYNAME (
    store_name      IN      VARCHAR2)
RETURN INTEGER;
```

### Parameters

**Table 53-37 GETFEATURESBYNAME Function Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

### Return Values

A bit mask of supported features (see [FEATURES\\_T Table Type](#))

## 53.7.20 GETFEATURESBYPATH Function

This function returns features of a store by path.

### Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYPATH (
    path           IN      PATH_T)
RETURN INTEGER;
```

### Parameters

**Table 53-38 GETFEATURESBYPATH Function Parameters**

| Parameter | Description |
|-----------|-------------|
| path      | PATH_T      |

### Return Values

A bit mask of supported features (see [FEATURES\\_T Table Type](#))

## 53.7.21 GETPATH Procedures

This procedure returns existing path items (such as files and directories). This includes both data and metadata (properties).

The client can request (using `prop_flags`) that specific properties be returned. File path names can be read either by specifying a BLOB locator using the `prop_data` bitmask in `prop_flags` (see [Table 53-9](#)) or by passing one or more `RAW` buffers.

When `forUpdate` is 0, this procedure also accepts a valid `asof` timestamp parameter as part of `ctx` that can be used by stores to implement "as of" style flashback queries. Mutating versions of the `GETPATH` Procedures do not support these modes of operation.

## Syntax

```
DBMS_DBFS_CONTENT.GETPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content       OUT        NOCOPY BLOB,
    item_type     OUT          INTEGER,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    asof          IN          TIMESTAMP  DEFAULT NULL,
    forUpdate     IN          BOOLEAN    DEFAULT FALSE,
    deref         IN          BOOLEAN    DEFAULT FALSE,
    store_name    IN          VARCHAR2   DEFAULT NULL,
    principal     IN          VARCHAR2   DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.GETPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    content       OUT        NOCOPY BLOB,
    item_type     OUT          INTEGER,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    asof          IN          TIMESTAMP  DEFAULT NULL,
    forUpdate     IN          BOOLEAN    DEFAULT FALSE,
    deref         IN          BOOLEAN    DEFAULT FALSE,
    store_name    IN          VARCHAR2   DEFAULT NULL,
    principal     IN          VARCHAR2   DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.GETPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount        IN OUT      NUMBER,
    offset        IN          NUMBER,
    buffers       OUT        NOCOPY RAW,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    asof          IN          TIMESTAMP  DEFAULT NULL,
    store_name    IN          VARCHAR2   DEFAULT NULL,
    principal     IN          VARCHAR2   DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.GETPATH (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    amount        IN OUT      NUMBER,
    offset        IN          NUMBER,
    buffers       OUT        NOCOPY RAW,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    asof          IN          TIMESTAMP  DEFAULT NULL,

    principal     IN              VARCHAR2  DEFAULT NULL);

```

## Parameters

**Table 53-39 GETPATH Procedure Parameters**

| Parameter  | Description                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to path items                                                                                                                                                                                                                                                    |
| properties | One or more properties and their values to be returned depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                               |
| content    | BLOB holding data which populates the file (optional)                                                                                                                                                                                                                         |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                                                                                                                                                             |
| amount     | On input, number of bytes to be read. On output, number of bytes read                                                                                                                                                                                                         |
| offset     | Byte offset from which to begin reading                                                                                                                                                                                                                                       |
| buffer     | Buffer to which to write                                                                                                                                                                                                                                                      |
| buffers    | Buffers to which to write                                                                                                                                                                                                                                                     |
| prop_flags | Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| asof       | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes                                                                                                                                                                  |
| forUpdate  | Specifies that a lock should be taken to signify exclusive write access to the path item                                                                                                                                                                                      |
| deref      | If nonzero, attempts to resolve the given path item to actual data provided it is a reference                                                                                                                                                                                 |
| store_name | Name of store                                                                                                                                                                                                                                                                 |
| principal  | Agent (principal) invoking the current operation                                                                                                                                                                                                                              |

## 53.7.22 GETPATHBYMOUNTID Function

If the underlying GUID is found in the underlying store, this function returns the full absolute path name.

### Syntax

```
DBMS_DBFS_CONTENT.GETPATHBYMOUNTID (  
    store_mount      IN      VARCHAR2,  
    guid             IN      INTEGER)  
RETURN VARCHAR2;
```

### Parameters

**Table 53-40** GETPATHBYMOUNTID Function Parameters

| Parameter   | Description                                                       |
|-------------|-------------------------------------------------------------------|
| store_mount | Mount point in which the path item with <code>guid</code> resides |
| guid        | Unique ID for the path item                                       |

### Usage Notes

If the GUID is unknown, a `NULL` value is returned. Clients are expected to handle this as appropriate.

### Return Values

Path of the path item represented by GUID in `store_mount`

## 53.7.23 GETPATHBYSTOREID Function

If the underlying GUID is found in the underlying store, this function returns the store-qualified path name.

### Syntax

```
DBMS_DBFS_CONTENT.GETPATHBYSTOREID (  
    store_name       IN      VARCHAR2,  
    guid             IN      INTEGER)  
RETURN VARCHAR2;
```

### Parameters

**Table 53-41** GETPATHBYSTOREID Function Parameters

| Parameter  | Description                                  |
|------------|----------------------------------------------|
| store_name | Name of store                                |
| guid       | Unique ID representing the desired path item |

### Usage Notes

If the GUID is unknown, a `NULL` value is returned. Clients are expected to handle this as appropriate.

Return Values

Store-qualified path name represented by the GUID

53.7.24 GETPATHNOWAIT Procedures

This procedure implies that the operation is for an update, and, if implemented, allows providers to return an exception (ORA-00054) rather than wait for row locks.

See FEATURE\_NOWAIT in [Table 53-5](#) for more information.

Syntax

```
DBMS_DBFS_CONTENT.GETPATHNOWAIT (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content       OUT          BLOB,
    item_type     OUT          INTEGER,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    deref         IN          BOOLEAN      DEFAULT FALSE,
    store_name    IN          VARCHAR2     DEFAULT NULL,
    principal     IN          VARCHAR2     DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATHNOWAIT (
    path          IN          VARCHAR2,
    properties    IN OUT NOCOPY PROPERTIES_T,
    content       OUT          BLOB,
    item_type     OUT          INTEGER,
    prop_flags    IN          INTEGER      DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),

    deref         IN          BOOLEAN      DEFAULT FALSE,
    store_name    IN          VARCHAR2     DEFAULT NULL,
    principal     IN          VARCHAR2     DEFAULT NULL);
```

Parameters

Table 53-42 GETPATHNOWAIT Procedure Parameters

| Parameter  | Description                                                                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to path items                                                                                                                                                                                                                                        |
| properties | One or more properties and their values to be returned depending on prop_flags (see <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> )                                                                                                                   |
| content    | BLOB holding data which populates the file (optional)                                                                                                                                                                                                             |
| item_type  | Type of the path item specified (see <a href="#">Table 53-4</a> )                                                                                                                                                                                                 |
| prop_flags | Determines which properties are returned. Default is PROP_STD. Specifies properties to be returned by setting prop_spec, and providing an instance of the <a href="#">DBMS_DBFS_CONTENT_PROPERTIES_T Table Type</a> with properties whose values are of interest. |
| asof       | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes                                                                                                                                                      |

**Table 53-42 (Cont.) GETPATHNOWAIT Procedure Parameters**

| Parameter  | Description                                                                                   |
|------------|-----------------------------------------------------------------------------------------------|
| deref      | If nonzero, attempts to resolve the given path item to actual data provided it is a reference |
| store_name | Name of store                                                                                 |
| principal  | Agent (principal) invoking the current operation                                              |

## 53.7.25 GETSTOREBYMOUNT Function

This function returns a store by way of its name.

### Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYMOUNT (  
    store_mount      IN      VARCHAR2)  
    RETURN STORE_T;
```

### Parameters

**Table 53-43 GETSTOREBYMOUNT Function Parameters**

| Parameter   | Description                                     |
|-------------|-------------------------------------------------|
| store_mount | Location at which the store instance is mounted |

### Return Values

[STORE\\_T Record Type](#)

## 53.7.26 GETSTOREBYNAME Function

This function returns a store by way of its name.

### Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYNAME (  
    store_name      IN      VARCHAR2)  
    RETURN STORE_T;
```

### Parameters

**Table 53-44 GETSTOREBYNAME Function Parameters**

| Parameter  | Description   |
|------------|---------------|
| store_name | Name of store |

### Return Values

[STORE\\_T Record Type](#)

## 53.7.27 GETSTOREBYPATH Function

This function returns a store by way of its path.

### Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYPATH (  
    path      IN      PATH_T)  
    RETURN STORE_T;
```

### Parameters

**Table 53-45** GETSTOREBYPATH Function Parameters

| Parameter | Description |
|-----------|-------------|
| path      | PATH_T S    |

### Return Values

[STORE\\_T Record Type](#)

## 53.7.28 GETSTATS Procedure

This procedure returns information about DBMS\_DBFS\_CONTENT statistics collection.

### Syntax

```
DBMS_DBFS_CONTENT.GETSTATS (  
    enabled      OUT      BOOLEAN,  
    flush_time   OUT      INTEGER,  
    flush_count  OUT      INTEGER);
```

### Parameters

**Table 53-46** GETSTATS Procedure Parameters

| Parameter   | Description                                               |
|-------------|-----------------------------------------------------------|
| enabled     | Whether statistics collection is enabled                  |
| flush_time  | How often to flush the statistics to disk in centiseconds |
| flush_count | Number of operations to allow between statistics flushes  |

## 53.7.29 GETTRACE Function

This function returns whether DBMS\_DBFS\_CONTENT tracing is turned on or not.

### Syntax

```
DBMS_DBFS_CONTENT.GETTRACE  
    RETURN INTEGER.
```

### Return Values

Returns zero if tracing is off, non-zero if tracing is on.

## 53.7.30 GETVERSION Function

This function marks each version of the DBMS\_DBFS\_CONTENT interface.

### Syntax

```
DBMS_DBFS_CONTENT.GETVERSION (
    RETURN VARCHAR2;
```

### Return Values

A string enumerating the version of the DBMS\_DBFS\_CONTENT interface in standard naming convention: string: *a.b.c* corresponding to *major*, *minor*, and *patch* components.

## 53.7.31 ISPATHLOCKED Procedure

This procedure checks if any user-level locks are applied on a given path.

### Syntax

```
DBMS_DBFS_CONTENT.ISPATHLOCKED (
    path          IN      VARCHAR2,
    who           IN      VARCHAR2,
    lock_type     IN OUT  INTEGER,
    store_name    IN      VARCHAR2  DEFAULT NULL,
    principal     IN      VARCHAR2  DEFAULT NULL);
```

### Parameters

**Table 53-47 ISPATHLOCKED Procedure Parameters**

| Parameter  | Description                                                       |
|------------|-------------------------------------------------------------------|
| path       | Name of path to file items                                        |
| who        | Transaction identifier that has locked the path                   |
| lock_type  | One of the available lock types (see <a href="#">Table 53-6</a> ) |
| store_name | Name of store                                                     |
| principal  | Agent (principal) invoking the current operation                  |

## 53.7.32 LIST Function

This function lists the path items in the specified path meeting the specified filter and other criteria.

### Syntax

```
DBMS_DBFS_CONTENT.LIST (
    path          IN      VARCHAR2,
    filter        IN      VARCHAR2  DEFAULT NULL,
    recurse      IN      INTEGER    DEFAULT 0,
    asof         IN      TIMESTAMP  DEFAULT NULL,
    store_name    IN      VARCHAR2  DEFAULT NULL,
    principal     IN      VARCHAR2  DEFAULT NULL)
RETURN DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

## Parameters

**Table 53-48 LIST Function Parameters**

| Parameter  | Description                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------|
| path       | Name of path to directories                                                                                                    |
| filter     | A filter, if any, to be applied                                                                                                |
| recurse    | If 0, do not execute recursively. Otherwise, recursively list the contents of directories and files below the given directory. |
| asof       | The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes                   |
| store_name | Name of repository                                                                                                             |
| principal  | Agent (principal) invoking the current operation                                                                               |

## Return Values

[DBMS\\_DBFS\\_CONTENT\\_LIST\\_ITEMS\\_T Table Type](#)

### 53.7.33 LISTALLPROPERTIES Function

This function returns a table of all properties for all path items in all mounts.

#### Syntax

```
DBMS_DBFS_CONTENT.LISTALLPROPERTIES
RETURN PROP_ITEMS_T PIPELINED;
```

## Return Values

[PROP\\_ITEMS\\_T Table Type](#)

### 53.7.34 LISTALLCONTENT Function

This function lists all path items in all mounts.

#### Syntax

```
DBMS_DBFS_CONTENT.LISTALLCONTENT
RETURN PATH_ITEMS_T PIPELINED;
```

## Return Values

[PATH\\_ITEMS\\_T Table Type](#)

### 53.7.35 LISTMOUNTS Function

This function lists all available mount points, their backing stores, and the store features.

#### Syntax

```
DBMS_DBFS_CONTENT.LISTMOUNTS
RETURN MOUNTS_T PIPELINED;
```

## Return Values

### MOUNTS\_T Table Type

## Usage Notes

A single mount results in a single returned row, with its `store_mount` field of the returned records set to `NULL`.

## 53.7.36 LISTSTORES Function

This function lists all available stores and their features.

## Syntax

```
DBMS_DBFS_CONTENT.LISTSTORES
  RETURN STORES_T PIPELINED;
```

## Return Values

### STORES\_T Table Type

## Usage Notes

The `store_mount` field of the returned records is set to `NULL` (since mount-points are separate from stores themselves).

## 53.7.37 LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

## Syntax

```
DBMS_DBFS_CONTENT.LOCKPATH (
  path          IN      VARCHAR2,
  who           IN      VARCHAR2,
  lock_type     IN      INTEGER,
  waitForRowLock IN      INTEGER      DEFAULT 1,
  store_name    IN      VARCHAR2     DEFAULT NULL,
  principal     IN      VARCHAR2     DEFAULT NULL);
```

## Parameters

**Table 53-49 LOCKPATH Procedure Parameters**

| Parameter                   | Description                                                       |
|-----------------------------|-------------------------------------------------------------------|
| <code>path</code>           | Name of path to file items                                        |
| <code>who</code>            | Transaction identifier that has locked the path                   |
| <code>lock_type</code>      | One of the available lock types (see <a href="#">Table 53-6</a> ) |
| <code>waitForRowLock</code> | Determines if a row is locked by a transaction or not             |
| <code>store_name</code>     | Name of store                                                     |
| <code>principal</code>      | Agent (principal) invoking the current operation                  |

## 53.7.38 MOUNTSTORE Procedure

This procedure mounts a previously registered store and binds it to the mount point.

### Syntax

```
DBMS_DBFS_CONTENT.MOUNTSTORE (
    store_mount    in    VARCHAR2    DEFAULT NULL,
    singleton      in    BOOLEAN     DEFAULT FALSE,
    principal      in    VARCHAR2    DEFAULT NULL,
    owner          in    VARCHAR2    DEFAULT NULL,
    acl            in    VARCHAR2    DEFAULT NULL,
    asof           in    TIMESTAMP   DEFAULT NULL,
    read_only      in    BOOLEAN     DEFAULT FALSE);
```

### Parameters

**Table 53-50 MOUNTSTORE Procedure Parameters**

| Parameter   | Description                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------|
| store_mount | Path name to use to mount this store                                                                         |
